1819.
PUNISHMENT, a penalty imposed upon the commission of some crime or offence against the laws. It is essential to the nature of a law, that it import or decree a punishment to the transgressors of it.

Solon very justly asserted, that the two great stimulants of human action being hope and fear, a good government could not possibly exist without an equitable system of rewards and punishments.

The forms and manners of punishment are various in various countries and ages, and for various crimes; as treason, felony, adultery, parricide, &c.

There was a time, says Beccaria, when all punishments were pecuniary. The crimes of the subjects were the inheritance of the prince, so that an injury done to society was a favour to the crown, and the sovereign and magistrates, those guardians of the public security, were interested in the violation of the laws. Crimes were tried at that time in a court of exchequer, and the cause became a civil suit between the person accused and the crown. The magistrate then possessed powers that were not necessary for the public welfare, and the criminal suffered punishments different from those which the necessity of example required. The judge was rather a collector for the crown, an agent for the treasury, than a protector and minister of the laws.

Among the Romans, the pecuniary punishments were the muleta and confiscatio. The corporal punishments were capitis diminutio, aque et ignis interdictio, proscription, deportatio, relegatio, surea, crux, carcer, culeus, equellus, sculeae, damnatio ad gladium, ad metallum, flagellatio, talio, &c. which fee described under their respective articles.

Among us the principal civil punishments are, fines, imprisonments, the stocks, pillory, burning in the hand, whipping, ducking-stool, hanging, beheading, quartering, burning, transportation, &c.

The ecclesiastical punishments are, excommunicatio, suspensio, dégradation, excommunication, anathemas, penances, &c. The military punishments are, being shot, running the gantetope, riding the wooden horse, the billows, &c.

Among the Turks, &c. impaling, bilinadoes on the foles of the feet, &c. obtain. See EMPALEMENT, &c.

The right of punishing crimes against the law of nature, as murder and the like, is in a state of more nature vested in every individual. Accordingly the first murderer, Cain, was so sensible of this, that we perceive him (Gen. iv. 14.) expressing his apprehensions, that whoever would find him would slay him. In a state of society, this right is transferred from individuals to the sovereign power; and thus men are prevented from being judges in their own causes, which is one of the evils that civil government was intended to remedy. The sword of justice is now vested by the consent of the whole community in the magistrate alone. Every punishment which does not arise from absolute necessity, says the great Montesquieu, is tyrannical; and this proposition is rendered more general by Beccaria, who observes, that every act of authority of one man over another, for which there is not an absolute necessity, is tyrannical. Upon this principle, the sovereign's right to punish crimes is founded; that is, upon the necessity of defending the public liberty, entrusted to his care, from the usurpation of individuals; and punishments are just in proportion, as the liberty, preferred by the sovereign, is sacred and valuable. It was necessity that forced men to give up a part of their liberty, and it is certain, that every individual would chuse to put into the public stock the smallest portion possible; as much only as was sufficient to engage others to defend it. The aggregate of these, the smallest portions possible, forms the right of punishing: all that extends beyond this is abuse, and not justice. The laws only can determine
the punishment of crimes; and the authority of making penal laws can only reside with the legislator, who represents the whole society, united by the social compact. No magistrate, therefore, as he is one of the society, can, with justice, inflict on any other member of the same society, punishment that is not ordained by the laws, nor exceed the punishment already determined by the laws. To the sovereign representing the society itself, who makes general laws to bind the members, it does not belong to judge, whether any individual has violated the social compact, or incurred the consequent punishment. In this case, there are two parties, represented by the sovereign, who inflicts upon the violation of the contract, and the other is the person accused, who denies it. It is necessary then, that there should be a third person to decide this contest; that is to say, a judge or magistrate, from whole determination there should be no appeal. Judges, in criminal cases, says Beccaria, have no right to interpret the penal laws, because they are not legislators. The lawful interpreter is the sovereign, that is, the representative of society, and not the judge, whose office is only to examine, if a man have, or have not committed an action contrary to the laws. Many evils arise from the erring infallibility of arbitrary interpretation.

The lawfulness of punishing criminals, who are chargeable with offences against the laws of society, that are only "mala prohibita," and not "mala in se," is founded upon this principle, that the law by which they suffer was made by their own consent; it is a part of the original compact into which they entered, when first they engaged in society; it was calculated for, and has long contributed to, their own security. This right, conferred by universal consent, gives to the state exactly the same power, and no more, over all its members, as each individual member had naturally over himself or others. Hence some have doubted how far a human legislature ought to inflict capital punishments for petty offences;—offences against the municipal law only, not against the law of nature; since no individual has, naturally, a power of inflicting death upon himself or others for actions in themselves indifferent.

With regard to offences "mala in se," capital punishments are in some instances inflicted by the immediate command of God himself to all mankind, as in the case of murder, by the precept delivered to Noah, their common ancestor and representative (Gen. ix. 6.), "Who so sheddeth man's blood, by man shall his blood be shed." In other instances they are inflicted after the example of the Creator, in his positive code of laws for the regulation of the Jewish republic; as in the case of the crime against nature. But they are sometimes inflicted without express warrant or example, at the will and discretion of the human legislature, as for forgery, for theft, and sometimes for offences of a lighter kind. None of these crimes are offences against nature, but only against social rights. The practice of inflicting capital punishments, for offences of human infraction, is thus justified by that great and good man, Sir Matthew Hale (1 Hal. P. C. 13.) "When offences grow enormous, frequent, and dangerous to a kingdom or state, destractive or highly pernicious to civil societies, and to the great insecurity and danger of the kingdom or its inhabitants, severe punishment and even death itself is necessary to be annexed to laws in many cases by the prudence of legislators." It is, therefore, as judge Blackstone observes, the enormity, or dangerous tendency of the crime, that alone can warrant any earthly legislature in putting him to death that commits it. It is not its frequency, only, or the difficulty of otherwise preventing it, that will excuse our attempting to prevent it by a wanton effusion of human blood. For, though the end of punishment is to deter men from offending, it can never follow from this circumstance, that it is lawful to deter them at any rate and by any means; since there may be unlawful methods of enforcing obedience even to the justest laws. Every humane legislator, as the learned judge remarks, will be therefore extremely solicitous of establishing laws that inflict the penalty of death, especially for flight offences, or such as are merely positive. Nor will it avail to allege that no lighter penalty will be effectual, because experience has not taught us that capital punishments are more effectual. Was the vast territory of all the Russias, it may be asked, worse regulated under the emperors Elizabeth, than under her more sagacious predecessors? or Has it been done, under Catherine II., less civilized, less social, and less secure? And yet we are assured, that neither of those illustrious princesses have, throughout their whole administration, inflicted the penalty of death; and the latter, upon a full persuasion of its being unfair, and even pernicious, issued orders for abolishing it entirely throughout her extensive dominions. But if capital punishments, says Blackstone, were proved by experience to be a sure and effectual remedy, that would not prove the necessity (upon which the justice and propriety depend) of inflicting them upon all occasions, when other expedients fail. This reasoning would, as we may justly apprehend, extend much too far. Where the evil to be prevented is not adequate to the pain of the punishment, a sovereign that thinks seriously can never reconcile laws that inflict death to the dictates of confidence and humanity. To shed the blood of our fellow-creatures, says the learned and humane judge, is a matter that requires the greatest deliberation, and the fullest conviction of our own authority; for life is the immediate gift of God to man; which neither he can resign, nor can it be taken from him, unleas by the command or per mission of him who gave it; either expressly revealed or collected from the laws of nature or society by clear and indisputable demonstration. Blackstone, however, would not be understood to deny the right of the legislature in any country to enforce its own laws by the death of the transgressor, though some persons of abilities have doubted it. To this class of persons we may refer the ingenious writer already cited. The unfeels profusion of punishments, which has never made man better, has induced Beccaria to enquire, whether the punishment of death be really just or useful in a well-governed state? What right, he asks, have men to cut the throats of their fellow-creatures? Certainly not that on which the sovereignty and laws are founded. The laws are only the sunk of the smallest portions of the private liberties of each individual, and represent the general will, which is the aggregate of that of each individual. Did any one ever give to others the right of taking away his life? Is it possible that in the smallest portions of the liberty of each, sacrificed to the good of the public, can be contained the greatest of all good, life? If it were so, how shall it be reconciled to the maxim which tells us, that a man has no right to kill himself? Which he certainly must have, if he could give it away to another. The punishment of death is not authorized by any right; for no such right exists. The death of a citizen cannot be necessary, but in one case; when, though deprived of his liberty, he has such power and connections as may endanger the security of the nation; when his existence may produce a dangerous revolution in the established form of government. But even in this case, it can only be necessary when a nation is on the verge of recovering or losing its liberty; or in times of absolute anarchy, when the disorders themselves hold the place of laws.

If the experience of all ages be not sufficient to prove, that the punishment of death has never prevented determined
PUNISHMENT.

men from injuring society; if the example of the Romans; if twenty years reign of Elizabeth, empress of Russia, in which she gave the fathers of their country an example more illustrious than many conquests bought with blood; if, says Beccaria, all this be not sufficient to persuade mankind, who always suspect the voice of reason, and who chuse rather to be led by authority, let us consult human nature in proof of this assertion.

It is not the intenseness of the pain that has the greatest effect on the mind, but its continuance; for our sensibility is more easily and more powerfully affected by weak but repeated impressions, than by a violent, but momentary, impulse. The power of habit is universal over every sensible being. As it is by that we learn to speak, to walk, and to satisfy our necessities, so the ideas of morality are stamped on our minds by repeated impressions. The death of a criminal is a terrible but momentary spectacle, and therefore a less efficacious method of deterring others, than the continued example of a man deprived of his liberty, condemned, as a beast of burden, to repair, by his labour, the injury he has done to society. "If I commit such a crime," says the Spectator to himself, "I shall be reduced to that miserable condition for the rest of my life." A much more powerful preventive than the fear of death, which men always behold in distant obscurity.

The terrors of death make so flight an impression, that it has not force enough to withstand the forgetfulness natural to mankind, even in the most essential things; especially when assailed by the passions. Violent impressions surprise us, but their effect is momentary; they are fit to produce those revolutions which instantly transform a common man into a Lacedemonian or a Persian; but in a free and quiet government they ought to be rather frequent than strong.

The execution of a criminal is, to the multitude, a spectacle, which in some excites compunction mixed with indignation. Thse sentiments occupy the mind much more than that fatal terror which the laws endeavour to inspire; but in the contemplation of continued suffering, terror is the only, or at least predominant sensation. The severity of a punishment should be just sufficient to excite compunction in the spectators, as it is intended more for them than for the criminal.

A punishment, to be just, should have only that degree of severity which is sufficient to deter others. Now there is no man, who, upon the least reflection, would put in competition the total and perpetual loss of his liberty, with the greatest advantages he could possibly obtain in consequence of a crime. Perpetual slavery, then, has in it all that is necessary to deter the most hardened and determined, as much as the punishment of death:—it has even more. There are many who can look upon death with intrepidity and firmness; some through fanaticism, and others through vanity, which attends us even to the grave; others from a desperate resolution, either to get rid of their misery, or ceafe to live; but fanaticism and vanity forfake the criminal in flavery, in chains and fetters, in an iron cage; and despair seems rather the beginning than the end of their misery. The mind, by collecting itself and uniting all its force, can, for a moment, repel affailing grief; but its most vigorous efforts are insufficient to refit perpetual wretchedness.

In all nations, where death is used as a punishment, every example supposes a new crime committed. Whereas in perpetual slavery, every criminal affords a frequent and laffing example; and if it be neceffary that men should often be witnessies of the power of the laws, criminals should often be put to death; but this supposes a frequency of crimes; and from hence this punishment will ceafe to have its effect, fo that it must be ufeful and ufefles at the fame time.

We shall be told, that perpetual slavery is as painful a punishment as death, and therefore as cruel. To which we anfwer, that if all the miserable moments in the life of a slave were collected into one point, it would be a more cruel punishment than any other; but these are scattered through his whole life, whilst the pain of death exerts all its force in a moment. There is also another advantage in the punishment of slavery, which is, that it is more terrible to the spectator than to the sufferer himfelf; for the spectator confiders the sum of all his wretched moments, whilst the sufferer, by the milery of the preffent, is prevented from thinking of the future. All evils are incréased by the imagination, and the sufferer finds reafons and confolations, of which the spectators are ignorant; who judge by their own fensibility of what paffes in a mind, by habit grown callous to misfortune.

He who foresees that he must pafs a great number of years, even his whole life, in pain and flavery; a slave to thofe laws by which he was protected; in flight of his fellow citizens, with whom he lives in freedom and society; makes an ufeful comparifon between thofe evils, the uncertainty of his fuccefs, and the shortnefs of the time in which he fhall enjoy the fruits of his transgression. The example of thofe wretches continually before his eyes, makes a much greater impression on him than a punishment, which, instead of correcting, makes him more obdurate.

The punishment of death is pernicious to society, from the example of barbarity it affords. If the passions, or the neceffity of war, have taught men to shed the blood of their fellow creatures, the laws, which are intended to moderate the ferocity of mankind, should not increase it by examples of barbarity, the more horrible, as this punishment is usually attended with formal pageantry. Is it not abfur'd, that the laws, which delteft and punifh homicide, shou'd, in order to prevent murder, publicly commit murder themfelves? What are the true and most ufeful laws? Thofe compacts and conditions which all would propofe and obferve, in thofe moments when private interest is filent, or combined with that of the public. What are the natural sentiments of every perfon concerning the punishment of death? We may read them in the contempt and indignation with which every one looks on the executioner, who is nevertheless an innocent executor of the public will; a good citizen, who contributes to the advantage of society; the fentiments of the general security without, as good fathers are without. Whaf then is the origin of this contradiction? Why is this sentiment of mankind indelible, to the scandal of reafon? It is, that in a fecret corner of the mind, in which the original impressions of nature are fiill preferv'd, men difcover a fentiment which tells them, that their lives are not lawfully in the power of any one, but of that neceffity only, which with its iron fceptre rules the univerfe.

What muft men think, when they fee wife magiftrates and grave minif ters of justice, with indifference and tranquility, dragging a criminal to death, and whifl a wretch trembles with agony, expecting the fatal stroke, the judge, who has condemned him, with the coldeft infenfibility, and perhaps with no fmal gratification from the exertion of his authority, quits his tribunal to enjoy the comforts and pleasures of life? They will fay, "Ah! thofe cruel formalities of justice are a cloak to tyranny, they are a fecret fign, a solemn veil, intended to conceal the word by which we are sacrificed to the infatiable idol of deputation. Murder, which they would reprefent to us as an horrible crime, we fee praftifed by them without repugnance, or remorse. Let us follow their ex-
ample. A violent death appeared terrible in their descriptions, but we see that it is the affair of a moment. It will be still less terrible to him, who, not expecting it, escapes almost all the pain.' Such is the fatal, though absurd reasoning of men who are disposed to commit crimes; on whom, the abuse of religion has more influence than religion itself.

How happy were mankind, says this author, if laws were now to be formed; now that we see on the thrones of Europe, benevolent monarchs, friends to the virtues of peace, to the arts and sciences, fathers of their people, though crowned yet citizens; the increase of whose authority augments the happiness of their subjects, by destroying that intermediate delphiopit, which intercepts the prayers of the people, to the throne. If these humane princes have suffered the old laws to subsist, it is doubtless because they are deterred by the numberless obstacles, which oppose the subversion of errors established by the function of many ages; and therefore every wise citizen will wish for the increase of their authority.

It has long since been observed, says Voltaire, to whom the commentary on Boccaria's effay is attributed, that a man after he is hanged is good for nothing, and that punishments invented for the good of society, ought to be useful to society. It is evident, that a score of stout robbers, condemned for life to some public work, would serve the state in their punishment, and that hanging them is a benefit to nobody but the executioner.

There have been some judges, says this writer, who were passionately fond of seeing human blood; such was Jefferies in England, and such in France was the man whom they called Conspicacite. Nature never intended such men for magistrates, but for executioners.

As to the end, or final cause of human punishments, this is not to be considered as an atonement or expiation for the crime committed, but as a precaution against future offences of the same kind. This purpose is accomplished in three ways; either by the amendment of the offender himself, with a view to which all corporal punishments, fines, and temporary exile or imprisonment are inflicted; or by deterring others by the dread of his example from committing similar offences, 44 ut pena (as Cicero expresses it, pro Cluentio, 45) ad pauros, metus ad omnes pervenient 46 or, lastly, by depriving the party who offends and injures mankind of the power to do future mischief, which is effected by either putting him to death, or condemning him to perpetual confinement, slavery, or exile. The method of inflicting punishment, however, ought always to be proportioned to the particular purpose it is meant to serve, and by no means to exceed it; and therefore the pains of death, and perpetual disability by exile, slavery, or imprisonment, ought never to be inflicted, but when the offender appears incorrigible.

The measure of human punishments must be left to the arbitration of the legislature, which should inflict such penalties as are warranted by the laws of nature and society, and such as appear to be the best calculated to answer the end of precaution against future offences. Some have recommended, and highly extolled for its equity, the "lex talonitis," or law of retaliation; but judge Blackstone observes, that this cannot be in all cases an adequate or permanent rule of judgment. Although there cannot be any regular or determinate method of rating the quantity of punishments for crimes, by any one uniform rule, applicable to all cases; and without ultimately referring to the will and discretion of the legislative power; yet there are some general principles, deduced from the nature and circumstances of the crime, that may afford some assistance in allotting to it an adequate punishment. One circumstance that serves in some measure to determine the nature and degree of punishment regards the object of it; for the more dignified in respect of rank, character, and influence, the object of an injury is, so much greater care should be taken to prevent that injury, and of course under this aggravation the punishment should be more severe. Accordingly treason in confining the king's death, is by the English law punished with greater rigour than even actually killing any private subject. Moreover, the violence of passion, or temptation may, in some cases, alleviate a crime; such is theft in cafe of hunger, contradiitigualified from the fame crime committed through avarice, and to serve the purposes of luxury. Homicide, in confection of sudden and violent resentment, is left penal than upon cool deliberate malice. The age, education, and character of the offender; the repetition (or otherwise) of the offence; the time, the place, the company in which it was committed; all these, and a thousand other incidents, may aggravate or extenuate the crime. Thus Demolthanes (in his oration against Midas) finely marks up the aggravations of the infults he had received: "I was abused," says he, "by my enemy, in cold blood, out of malice, not by heat of wine, in the morning, publicly, before strangers as well as citizens; and that in the temple, whether the duty of my office called me."

Farther, as punishments are chiefly intended for the prevention of future crimes, those should be most severely punished, which are the most destructive of the public safety and happiness; and, among crimes of an equal malignity, those which a man has the most frequent and easy opportunity of committing, which cannot be so easily guarded against as others, and which, therefore, the offender has the strongest inducement to commit; according to Cicero's observation (Pro Sexto Rofcio, 40); "ea funt animadver- tenda peccata maxime, quae difficilium praecautum." We may also observe, that punishments of unreasonable severity, especially when indiscriminately inflicted, have less effect in preventing crimes, and amending the manners of a people, than such as are more mild or merciful in general, and yet properly intermixed with due delineations of severity. Crimes, says Boccaria, are more effectually prevented by the certainty than the severity of punishment. The certainty of a small punishment will make a stronger impression, than the fear of one more severe, if attended with the hopes of escaping; for it is the nature of mankind to be terrified at the approach of the smallest inevitable evil, whilst hope, the best gift of heaven, hath the power of dispelling the apprehension of a greater; especially if supported by examples of impunity, which weaken or avarice too frequently afford.

If punishments be very severe, men are naturally led to the perpetration of other crimes, to avoid the punishment due to the first. The countries and times most notorious for severity of punishments, were always those in which the most bloody and inhuman actions and the most atrocious crimes were committed; for the hand of the legislator and the aifain were directed by the fame spirit of ferocity; which, on the throne, dictated laws of iron to slaves and savages, and, in private, infligted the subject to sacrifice one tyrant to make room for another.

In proportion as punishments become more cruel, the minds of men, as a fluid rises to the same height with that which surrounds it, grow hardened and insensible; and the force of the passions full continuing, in the space of an hundred years, the wheel terrifies no more than formerly the prizen. That a punishment may produce the effect required,
PUNISHMENT.

It is sufficient that the evil it occasions should exceed the good expected from the crime; including in the calculation the certainty of the punishment, and the privation of the expected advantage. All severity beyond this is superfluous, and therefore tyrannical.

There are yet two other confquences of cruel punishments, which counteract the purpose of their institution, which was, to prevent crimes. The first arises from the impossibility of establishing an exact proportion between the crime and punishment, for though ingenious cruelty hath greatly multiplied the variety of tortures, yet the human frame can suffer only to a certain degree, beyond which it is impossible to proceed, be the enormity of the crime ever fo great. The second confquence is impunity. Human nature is limited no less in evil than in good. Excessive barbarity can never be more than temporary; it being impossible that it should be supported by a permanent fystem of legislation; for if the laws be too cruel they must be altered, or anarchy and impunity will succeed. The excessive severity of laws (says Montefquieu, Sp. of Laws, b. 6. c. 13.) hinders their execution; when the punishment surpasses all measure, the public will frequently, out of humanity, prefer impunity to it.

Thus also the statute 1 Mar. st. 1. c. 1. recites in its preamble, "that the state of every king confuits more affuredly in the love of the subject towards his prince, than in the dread of laws made with rigorous pains; and that laws made for the preservation of the commonwealth without great penalties, are more often obeyed and kept, than laws made with extreme punishments." Happy had it been for the nation, says judge Blackstone, if the subsequent practice of that deluded princes, in matters of religion, had been correspondent to these sentiments of herself and parliament, in matters of state and government. It may be farther observed, that fanguinary laws are a bad symptom of the distemper of any state, or of leat of its weak constitution. The laws of the Roman kings, and the twelve tables of the decemvirs, were full of cruel punishments: the Porcian law, which exempted all citizens from sentence of death, silently abrogated them all. At this period the republic flourished: under the emperors fewer punishments were revived; and then the empire fell.

We may further add, that it is abfur'd and impolitic to apply the same punishment to crimes of different malignity. Besides, a multitude of sanguinary laws (besides the doubt that may be entertained concerning the right of making them) argues likewise a manifest defect either in the wisdom of the legislative, or the strength of the executive power. Although it be much easier to extirpate than to amend mankind; yet that malignity must be esteemed both a weak and a cruel surgeon, who cuts off every limb, which through ignorance or indiscretion he will not attempt to cure. Boccaia therefore proposes to form in every state a scale of crimes, with a corresponding scale of punishments, depending from the greatest to the least; but if this idea be deemed romantic, a wise legislator will at least mark the principal divisions, and not assign penalties of the first degree to offences of an inferior rank. When men fee no distinction made in the nature and gradations of punishment, the generality will be led to conclude, there is no distinction in the guilt. Much as we may be disposed to admire and extol the excellence of the English law in a variety of respects, yet none can otherwise than regret the frequency of its capital punishments: inflicted by a multitude of successive and independent statutes, upon crimes very different in their natures; and we cannot forbear paying our tribute of respect to Sir Samuel Romilly, whose talents and character far exceed our praise, and other legislators, who are laudably exerting themselves in simplifying and mitigating our penal code.

It is a melancholy truth, says judge Blackstone, that among the variety of actions, which men are daily liable to commit, no less than 160 have been declared by act of parliament to be felonies without benefit of clergy; or in other words, to be worthy of infall death. So dreadful a list, instead of diminishing, increases the number of offenders. The injured, through compunction, will often forbear to prosecute: juries, through compunction, will sometimes forget their oaths, and either acquit the guilty or mitigate the nature of the offence; and judges, through compunction, will reprieve one half of the convicts, and recommend them to the royal mercy. Among so many chances of escaping, the ready and hardened offender overlooks the multitude that fail; he boldly engages in some desperate attempt, to relieve his wants or supply his vices; and if, unexpectedly, the hand of justice overtakes him, he deems himself peculiarly unfortunate, in falling at last a victim to those laws, which long impunity has taught him to contemn.

Boccaia, whose excellent essay we have often cited in this article, observes, that the more immediately after the commissio of a crime, a punishment is inflicted, the more just and useful it will be. It will be more just, because it spares the criminal the cruel and superfluous torment of uncertainty, which increases in proportion to the strength of his imagination, and the fene of his weaknesses; and because the privation of liberty, being a punishment, ought to be inflicted before condemnation, but for as short a time as possible. Imprisonment, he says, being only the means of securing the person of the accused, until he be tried, condemned, or acquitted, ought not only to be of as short duration, but attended with as little severity as possible. The time should be determined by the necessary preparation for the trial, and the right of priority in the oldest prisoners. The confinement ought not to be clofer than is requisite to prevent his flight, or his concealing the proofs of the crime; and the trial should be conducted with all possible expedition. Can there be a more cruel contrariet than that between the indolence of a judge, and the painful anxiety of the accused; the comfort and pleasures of an infensible magistrate, and the filth and misery of the prisoner? In general, "The degree of the punishment, and the confquences of a crime, ought to be fo contrived, as to have the greatest possible effect on others, with the least possible pain to the delinquent." If there be any fertainty in which this is not a fundamental principle, it is an unlawful society; for mankind, by their union, originally intended to subject themselves to the least evils possible.

An immediate punishment is more useful; because the smaller interval of time between the punishment and the crime, the stronger and more lafting will be the allocation of the two ideas of crime and punishment; so that they may be considered, one as the cause, and the other as the unavoidable and necessary effect.

It is, then, of the greatest importance, that the punishment should succeed the crime as immediately as possible, if we intend, that in the rude minds of the multitude, the seducing picture of the advantage arising from the crime, should instantly awake the attendant idea of punishment. Delaying the punishment serves only to seperate these two ideas; and thus affects the minds of the spectators rather as being a terrible sight, than the necessary confquence of a crime; the horror of which should contribute to heighten the idea of the punishment.
PUNISHMENT.

There is another excellent method of strengthening this important connexion between the ideas of crime and punishment, that is, to make the punishment as analogous as possible to the nature of the crime; in order that the punishment may lead the mind to consider the crime in a different point of view, from that in which it was placed by the flattering idea of promised advantages. This ingenious writer closes his essay with the following general theorem, as the result of his previous reasoning. "That a punishment may not be an act of violence, of one or of many against a private member of society, it should be public, immediate, and necessary; the least possible in the cause given; proportioned to the crime, and determined by the law." Montesq. Sp. of Laws. Beccaria's Essay on Crimes and Punishments. Blacklt. Com. vol. iv.

A valuable work, comprising the subject of this article, was presented to the public in the year 1811 by M. Dumont of Geneva. It was formed of detached materials, furnished by the papers of Mr. Jeremiah Bentham, and the whole is executed with such judgment in the arrangement of the matter, and so much live interest and elegance as to the style of the composition, that M. Dumont appears more like an original author than an editor. This work would have afforded us many instructive and interesting extracts, if our limits had allowed our making that use of it, which it deserves. This, however, is the least necessary, as the reader may have access to the original treatise, viz. "Theorie des Pénal et des Recompenses; par M. Jeremiah Bentham, Jurisconsulte Anglois; redigée en Francais d'apres les Manuscrits, par M. Et. Dumont de Généve," 2 vol. 8vo. à Londres, 1811: or to the ample analysis of it in the Edinburgh Review, No. 43. A brief account of its contents may, however, be gratifying to our readers. This work consists of two great parts or branches; the theory of penal legislation, and the theory of remunerative legislation. The former contains in a systematical form all the principles that serve to regulate the choice of different modes of punishment and the apportionment of punishments to crimes. In the second are exhibited the principles upon which the lawgiver ought to proceed, when he holds out inducements either alone or attended with corresponding penalties, to influence the conduct of his subjects. The first book explains the general principles of the system, and opens with definitions and classifications.

Punishment, in its most general sense, is the infliction of some evil upon an individual, with an intention that he should suffer this evil, and with a reference to some act done or omitted. Punishment, in its legal sense, is the infliction of some evil, according to judicial forms, upon an individual convicted of some act forbidden by law, and with the intention of preventing the recurrence of such acts. Punishments, as well as crimes, are divisible into four classes, as they affect the person, the property, the reputation, or the condition of those upon whom they are inflicted. Those which affect the person, or corporal punishments, are subdivided into various species; they may be simple or complex, afflicting, or restrictive, or active (e.g., compulsory labour) or capital. The other three classes are all private, affecting the delinquent with loss or degradation. Hence arises another general classification of punishments, by dividing them into corporal and privitive.

From this definition it appears, that the object of all punishment is the prevention of the offence in future, either by the fame delinquent or by other persons in similar circumstances. The first end is accomplished in three ways; by taking from the offender the physical power of committing the offence; by taking away the desire; or by deterring him. The other, and principal object of the infliction, that of restraining others, can only be effected as far as the punishment is concerned, by the threat which it holds out of similar infliction. These objects, as they form the only just motives, constitute also the only justification of punishments. Although the direct and primary object of punishment is prevention, the civil magistrate, having provided for that object, has another duty to perform, which is to provide as far as possible for the repairation of the injury sustained through the crime committed.

The essence or effect of any punishment is, in the language of this system, the whole evil of every kind occasioned by it, including the sufferings of the delinquent, the loss of his labour or life to the public, the pecuniary cost of his punishment; and, in short, every thing endured, paid, or forgone, in order to obtain the double preventive which the punishment is intended to administer. The gain or profit of the punishment consists in this preventive, or in the tendency of the punishment to secure it. A punishment may be termed frugal or economical which produces the desired effect with as little suffering as possible; and it may be termed costly or prodigal, when the same effect might have been produced by a smaller degree of suffering. The real value is distinguished from the apparent value, of the suffering; the former being the actual amount of that which is inflicted; the latter, the portion of it which is exhibited, or otherwise made known to, and understood by the public. The essence of punishment is equivalent to the real amount; the profit is in proportion to the apparent amount only; and hence are deduced these important maxims: 1. That, ceteris paribus, a punishment easily comprehended, is preferable to one of difficult apprehension: 2. That one which takes hold of the memory, is preferable to one easily forgotten; 3. That one which is as great or greater in apparent than in real amount, is preferable to one which is really greater than it appears to be;—the excess of real amount being in truth so much thrown away, so far as regards the principal object, of general example.

The next subject of discussion comprehends the principles that ought to regulate the extent of punishment, for the prevention of crimes. These are contained in the following propositions. 1. The evil of the punishment must exceed the advantage arising from the crime; so that, generally speaking, the stronger the temptation to commit any crime, the more severe ought to be the punishment, subject to exceptions in extreme cases. 2. When the criminal act evidently indicates a habit or practice, the punishment should be proportioned, not to the gain derived from a single offence, but to the probable amount of profit flowing from a course of such conduct. 3. An addition must be made to the punishment, in order to compensate its want of certainty and proximity. 4. In cases where a temptation offers for the commission of different crimes, a more severe punishment should be denounced against the greater crime. 5. The more atrocious any crime is, the more safely may a less severe punishment be ventured upon, for the chance of preventing it. 6. The nominal amount of punishment for the same crime, must often be varied at the discretion of the judge, according to the circumstances of the delinquent, in order to preserve the real amount of suffering.

The qualities of punishment, the consideration of which naturally succeeds that of the measure or quantity, are such as follow: it should be divisible; invariable, or certain or equal; commensurable with others; analogous to the crime; exemplary; economical; remissible; that it should restrain the offender from doing harm; conducive to his reformation; yield a profit, in the ordinary sense of the word; be simple in its description;
PUNISHMENT.

description; and so far popular as to shock none of the established feelings or prejudices of the community. These qualities are, for the most part, understood as soon as they are mentioned. Some of them, however, undergo a more ample discussion than others. This is the case with respect to the qualities of analogy and popularity. One of the sources of analogy specified by Mr. Bentham is that of employing the same instrument or operation in the punishment, as the delinquent did in the crime, as, e. g. burning an encampment who had committed any aggravated act of arson, by which lives were sacrificed as well as property. Another method is that of inflicting on the delinquent the same injury which he offered to the innocent person. A third consists in subjecting to punishment the part of the body with which the offender committed the crime. A fourth, in affecting the face with some disfigurement similar to disfiguring, where part of the offense was the use of a disguise. Other analogies also are enumerated. In discussing the popularity of punishment, the author advert to the prevalence of false feelings and prejudices, and he reduces the errors proceeding from these causes to four heads; as they consist in mistaken notions of liberty, decency, religion, and humanity. The author allows, however, that a lawgiver should, for a time at least, frame his institutions so as to humour even the caprices and errors of his people, when he finds them too deeply rooted and widely spread, to be overcome or disregarded. To any speculative arguments, founded upon false views of those different subjects, of course no regard should be paid—as to those fancies in politics, religion, or sentiment, who would have no imprisonment because it violates liberty, or abolish capital punishments because they encroach upon the province of the Deity, or because they are painful to the feelings.

The author mentions four cafes, in which punishment is wholly inept, and ought not to be inflicted; viz. where the crime being either imaginary, or unfit for legislative interference, may be fain to exit, and the punishment would be unfounded; where the punishment would be wholly injurious on the delinquent, or others in the same circumstances, as in the case of idiots: where the means being sufficient to accomplish the end in view, punishment would be superfluous: where more evil being likely to result from punishing the particular offenders than from letting them escape, the infliction would be too costly, as in the cafe of an extensive mutiny or rebellion.

We have already stated, that the author divides punishments into two great classes, corporeal and privative; that he again subdivides corporeal punishments into five kinds, and privative into three. 1. The first class of corporeal punishments consists of punishments simply affictive, denoting those which cause bodily suffering, with little attendant injury; and even those mere simple, as the lath, are accompanied with a certain disgrace by their public exhibition, which is an essential part of the process. Of the various kinds of simple infliction, our author gives the preference to the lath, under certain modifications. 2. The second class consists of punishments complexly affictive, those in which the mere bodily suffering is attended with, or followed by, some other ills, either of personal comfort or reputation. These are subdivided into three kinds, comprehending those that are inflicted by deforming the person, which is done either by disfiguring, e. g. burning in the hand; or disfigurement, e. g. by cutting the nose, or cutting the ear; by disfiguring a limb or organ, without destroying it; by mutilating or destroying the part. The third class comprehends restrictive punishments, which prevent the offender from doing or enjoying something agreeable or useful to him. The restrictions thus imposed are of two kinds; simple prohibitions, and restraints upon loco-motion. The former are so limited in their application, that we need not particularly specify them; but the latter are divided into five kinds; viz. imprisonment, in the ordinary sense of the word; quasi-imprisonment, or confinement within the district to which the offender belongs; relegation, or confinement to some other district within the dominions of the state; local interdiction, or imprisonment from a particular district; banishment from the territories of the state, either indefinitely, or to some specific foreign part. Imprisonment, according to our author's statement, in order to be effectual, ought to place the offender, for a limited time, under the most complete restraint, instead of being long and flight. Mr. Bentham enlarges in the enumeration of the evils comprehended under this mode of suffering; of which some belong indispensably and necessarily to it; others such as are accidental, but most frequently accompany it; and others again such as arise from abuse of it. With imprisonment, he says, in certain cafes, and always for a very limited time, may most advantageously be joined solitudes, darkens, and regimen. Our author, having exposed the absurd system of "prison-fees," infers from his general principles that there ought to be three kinds of prisons, adapted to the several purposes of simple detention, penitentiary confinement, and perpetual imprisonment. The first being only applicable to the case of insolvent debtors guilty of imprudence or extravagance, and of accused persons kept for trial, should have no accompaniment whatever of rigour. The leading principle in distinguishing the two others is, that the subjects of the former are to enter again into society; while those of the latter, being for ever excluded from it, the exemplary nature of their sufferings should be the principal object of attention. The names of the three prisons, for these separate purposes, should be different, as well as their external appearance; and every thing which can feize hold of the imagination, without awakening sympathy, should be present, both in the construction of the perpetual prison, and in the situation of its inhabitants. 4. The fourth class of punishments comprehends those that are termed active or laborious. Punishments of this class, when examined by the rules already premised, are found to unite the greatest number of advantages with the fewest defects. In the discussion of this subject, the author directs our attention to what may be called the extreme cafe of mismanagement in this kind of punishments. Here he alludes to Botany Bay. The transportation of convicts to America, which preceded the present plan, with several disadvantages of great moment, was, upon the whole, infinitely preferable. It was grossly unequal, insufferable as it became linditute with exile to the poor, while it was only simple relegation to those who could pay for their pillage. It was defective too in preventive power, the opportunities of escape being necessarily great. In both these particulars, the deportation now practiced has the manifest advantage. All the convicts are equally under restraint, and their escape is much more difficult; but in every other point of view, it is either as bad, or a great deal worse. It is as little as possible exemplary: the disproportion between the real and apparent suffering,—the excess of the former,—is in truth a maximum. The community in this country fee a convict sent on a long voyage, to a fertile country, lying in a fine climate. This is the situation. The reality is, that the miserable wretch, after rotting in the hulks for a year or two, is crammed with some hundreds of his fellows into a floating prison, or, or it may be, a pelt-house, in which, if he survives the rilks of famine, pestilence, mutiny, fire, shipwreck, and explosion, he is conveyed, through the in-
PUNISHMENT.

fiction of a ten months' voyage, to a life of alternate slavery and rebellion, where guilty or cruel excess succeeds exquisite suffering, without varying the uniform misery, or changing the prevalent character of the body: and all this passes at the opposite extremity of the earth's diameter, from whence it operates no more in any manner of way upon the inhabitants of England, than if it were passing in the moon. The tendency of discipline in the colony to reform the convicts, supposing them to have arrived there, may easily be estimated. They are not separated from their companions in guilt; they have no better examples before them, no eyes to watch them. The partial historian of the rising settlement, himself the chief magistrate, (Mr. Collins,) has supplied us with the details; and, in spite of his inclination to see every thing in the fairest light, he has painted, if the pages of a journal for sixteen years may be paid to paint, by far the blackest picture ever yet exhibited of human society. His book is a catalogue of crimes; it would be a record of convictions, but that perjury so universally prevails as to ensure the escape of all who are not taken in the fact. The vice at the root of all the rest, a rage for spirits approaching to frenzy, can neither be cured, nor deprived of gratification. Far from improving by their reformation there, it was only at the first establishment that any remission of unfavourable symptoms appeared. As soon as the first convicts had finished their period of servitude, their liberty brought along with it an influx of disorder and contamination, which each succeeding year seems to increase. If this sytem, then, prevents the deliquent from repeating his crimes, it is only by transferring the scene of them to a distant settlement, where it softens and augments them; and, although, with reference to one part of the empire, this may be termed prevention, the legislator, whose care should embrace the whole, has no right to give it such a name. As to the pecuniary expense, by which so much evil is purchased, we find it in the parliamentary reports estimated at above a million in about ten years, or about thirty-eight pounds for each convict, besides the value of his labour. Last of all, the punishment inflicted is perfectly different from the one to which the sentence of the law has condemned the convict. Not to mention the detention before transportation, and the arrival sometimes when the term of punishment has nearly expired, the power of returning at its expiration is possessed by few men, and no women; while of the voyage some idea may be formed, from the average mortality between 1787 and 1795, being above one in ten; and from a jail fever, always a probable occurrence, on one occasion, in 1799, having carried off one hundred in three. If, in such a case, we could look to the settlement as a colonial speculation, we should find its gains a similar proportion; but this estimate would be as superficial after what has been said, as it would be foreign to the design of this inquiry.

In the work before us we have a general sketch of the author's plan of improvement upon this system, together with a view of its connection with the principles which he has unfolded, and of the prodigious advantages accruing from it. The "Panopticon" is distinguished by three leading properties. From the form of the building, and the disposition of the cells, the inspector can see each prisoner at all times, without being seen by them, and can direct them without leaving his post: the management of the establishment is carried on by contract, the government paying a fixed price for the whole expenses of each convict, and the contractor having the whole profit, as he has the entire charge and regulation, of the work to be performed, but allowing a certain proportion of the gain to the convict: the contractor infuses the lives and safe custody of the convicts; he is allowed yearly a certain sum for the deaths, as calculated from the common tables, and he pays the same sum for each death which actually does happen, and for every escape which takes place. If we mistake not, Mr. Bentham, by his contract with government, further engaged to pay so much for each prisoner who, after his discharge, should afterwards be convicted of any offence. The entire publicity of his accounts was another condition, and one upon which he himself insisted. The Panopticon was to be open at all times to every magistrate, and at certain hours to the public generally.

The most striking points of the comparison between both systems, as they are presented to us by the anonymous author of the article on the subject in the Edinburgh Review, are such as follow. The punishment is in the highest degree exemplary; it is all seen and understood; it appears much greater than it really is; the comforts of the convicts, in their intercourse with each other according to their improvement, and in the state of industry, and cleanliness, and wholesome regimen, for which they have exchanged their ordinary habits, being, however real, by no means such as strike the multitude of spectators, who only see confinement, compulsory labour, and ignominy. The reforming effects of the plan are equally manifest: the labour, to which they are in part allured by a fixed allowance of profit; the perfect temperance in which they live; the facility afforded of separating them into classes, according to their habits and behaviour; the means of easy instruction, both religious and other, which they give; all furnish as good a chance of reclaiming those unhappy persons who are not hardened in guilt, as from any such discipline can reasonably be expected. The preventive powers of the Panopticon are complete, while the convict remains in it; and although a relapse after liberation can only be guarded against by reformation, a contrivance is added to this establishment, admirably calculated to provide against the first dangers of the discharge: the convict is transferred to another place of mitigated confinement, where he is rather under inspection than in custody, and from whence he is gradually allowed wholly to withdraw. With respect to the cost of the plan, we may form some estimate of it from the terms of Mr. Bentham's contract. Each convict was to cost government £31. 10s., including 1/. 10s. for the proportion of the expenses of building and ground. He was to provide a fund for indemnifying the parties injured; to allow the convicts one quarter of the profits of their labour; and, after the first trial, to make a reduction in the charge. Practical men, well versed in such matters, had no doubt that a very considerable reduction might have been speedily afforded; and that in a few years, the profits would entirely defray the expenses of the establishment to the state. While all manner of delays and difficulties were thrown in the way of this experiment: while wits and jobbers, or, as they termed themselves, matter-of-fact men, averce to theories, and deprecating novelties, were employed in running it down; trials were made in America of penitentiary houses upon similar principles, though in a much less perfect shape, and without some of Mr. Bentham's chief improvements. We have the most irrefragable testimony borne to their success, by the interesting narratives of the duc de Rochefoucault Liancourt and captain Turnbull; the one a person eminently skilled in the subject of prisons; the other a mere practical observer, imbued with no knowledge beyond that of the naval profession. Both these very different witnesses concur in their statement of the salutary consequences of the plan; and if we wished to find a perfect contrast to the melancholy
PUNISHMENT.

melancholy narratives of Mr. Collins, we could certainly nowhere so well be suited as in the descriptions which the French and English travellers have given us of the convicts in New York and Philadelphia.

5. Capital punishments compose the fifth class. This class consists either of simply inflicting death with the least possible degree of suffering, or in accompanyng the destruction of life with torment. The latter method, at one period universally prevalent, and still known in most countries, is happily almost abolished in the two most civilized nations. In France, the Code Napoleon allowed it only in the cases of parricide, and attempts against the sovereign's life, where the addition made to the punishment of death is cutting off the right hand. In England, it is only in the case of high treason that such augmentations are allowed: the punishment of the law is no doubt barbarous in the extreme, but in practice it is always remitted. All such cruelties have the effect of inspiring pity in the spectators towards the criminal, and of rendering criminals more hardened and savage.

The ingenious author of the critique on Mr. Bentham's theory, to whose analysis of the work we are so much indebted in the compilation of this article, agrees with him in his objections to Beccaria, who maintains that a punishment of longer duration is more terrible to the spectator. Clearly there is none so dreadful as death. M. Dumont adds, that its apparent suffering is greater than its real, which applies only to the pains of it. On the other hand, it exceeds all others in some material defects; not only is it expensive, and beginning to become unpopular; it is quite irremissible, and it is in the highest degree unequal, and incapable of division or apportionment. A very satisfactory statement is given under this head, of the evil tendency of frequent executions, of the kind of reasoning by which offenders at the moment of temptation get rid of the fear of death, and especially of the wide difference between encountering certain destruction, and yielding to impulses which may lead to it. The evils arising from its being irremissible are also ably expounded; yet we think the author has neglected to consider how much of its horror consists in this quality. It is manifest that no other punishment can utterly exclude hope. In comparing capital with other punishments, our author is disposed to give the latter the preference, almost to the exclusion of the former; chiefly because, however exemplary to men in general the infliction of death may be, and how deep forever the impression it makes on their minds, it has not the same terrors for the clafs of men most likely to commit the worst offences, violent spirits and hardened delinquents. That its range should be extremely limited, we are willing to admit; but we differ from him in the position, that for this clafs of men, perpetual confinement to hard labour would have more terrors than death. The total extinction of life, without chance of escape, pardon, or mitigation, ought still to be denounced against the worst offences; and, by being confined to these, will unquestionably become doubly terrible. The evils arising collaterally from the abuse of this punishment, are so ably pointed out by Sir Samuel Romilly, that our author abridges a part of the treatise before us, by referring to his tract.

The other great division of punishments in Mr. Bentham's theory, consists more particularly in privation. These may be arranged in three clafs, as they impose a forfeiture of reputation, of property, or of condition. 1. Punishments which affect a man's reputation consist of appeals to public opinion, and are those measures which the lawgiver takes with respect to him, for directing that opinion against him. The lawgiver may inflict punishments of this kind, or rather may expose the offender to have them inflicted, either by simply denouncing, with the authority belonging to his functions, that certain acts shall be deemed infamous, or by treating the particular offender judicially in a certain way. The latter is the mode used in modern times; and it is practiced in different ways: by publication of the offence;—by judicial admonition;—by inflicting punishments of the other classes, corporal as well as privative, the immediate object of which is not the destruction of reputation;—by inflicting what may be termed quasi-corporal punishments, the sole object of which is infamy;—by degradation, or depriving the offender of his rank, natural or conventional;—by discrediting him, or preventing his testimony from being received.

2. The description of punishments affecting property consists of those which are pecuniary, and which are quasi-pecuniary, as confiscation of lands, &c. 3. The forfeiture of condition, or flatus, though a clafs of great extent, theoretically speaking, is in practice reduced within narrow limits. Marriage may be disallowed; children may be bastardized; blood may be corrupted; the different kinds of trust may be taken away; a person may be reduced to slavery; a community may be deprived of its rights and privileges. Outlawry may also be referred to this head.

There are other kinds of infliction, which every found principle teaches us to avoid where it is possible, and to diminish as much as possible, where, from the defects of all human contrivances, they inevitably mingle themselves with the legitimate modes of punishment. Our author's system arranges them in two classes; those which are misplaced, or which fall upon other persons than the offender; and those which are complicated, or present neither to the legislator, the judge, the party, nor the public, any fixed and definite idea. Those punishments that are misplaced, in the proper sense of the term, or which the legislator enacts with the intention of punishing another person than the offender, either along with him, or in his place, consist of four kinds; viz. vicarious, where the offender escapes:—transitive, where an innocent person is purposely punished who is connected with the offender:—collective, where a body of innocent persons suffer, in the presumption of the guilty being among them:—and fortuitous, where an innocent person suffers as well as the offender, though unconnected with him. The only infame of vicarious punishments is that inflicted upon the families and creditors of suicides by the law of England. This, like all other absurd and unjust laws, is evaded, in almost every instance, by perjury, and the exercise of discretion in a sovereign. The example given of transitive punishment is the corruption of blood, the absurdity of which is ably expounded. The chief instances of collective punishments are those in which corporations are punished for the faults of certain individual corporations; a proceeding which can never be justified. The well-known examples of fortuitous punishments are taken from the law of England. The most notable is the forfeiture and efeche of freehold property, in cases of attaint of treason and felony, where the confiscation relates back to the commissiort of the offence, and all moneys conveyances are avoided; so that a man may commit a secret crime, and sell his estate to an ignorant and innocent purchaser, in whose hands the crown or the lord afterwards seizes the estate upon the vendor's attaint; and as his goods and chattels are forfeited upon conviction, the only fund of compensation is gone also. Deodands are another infame of familiar injustice; and the punishment of incapacitating a person from giving evidence, is manifestly one which may
strike more injuriously at parties wholly unconnected with the offender, than at himself; besides, that it is by no means inflicted merely with the view of putting courts of justice on their guard against admitting a bad witness; for it is often the punishment of crimes which have no peculiar connection with violation of truth.

Among the evils of complicated punishments, we may reckon, besides outlawry and incapacitation of giving evidence, excommunication and felony. Some gross abuses having occurred in the infliction of the punishment of excommunication, several distinguished persons have undertaken to substitute other procedure in its place; and Sir W. Scott brought a bill into parliament with this view, so that the evil is done away. The punishment of persons as felons, comprehends a number of inflictions very different from each other, so that our author considers the punishing as a felon to be a vague and indefinite term. This comprehends two descriptions of punishment; the one capital, with forfeiture of lands and chattels; the other not capital, but consisting in forfeiture of chattels, and the form of burning in the hand; to which, by special enactment, imprisonment, transportation, or indeed any other punishment, may be superadded. It must be acknowledged, that a much simpler and better manner of slating the punishment due to an offence would be, to tell at once of what it is to be composed; and instead of enacting that certain offences are felonies, which specifies nothing, to prohibit them, and state the precise inflictions which shall follow the committal of them. For the general character and high commendation of the work, which has furnished the preceding materials, we refer to the Edinb. Rev. No. 45, p. 1-31.

Punishment, in Theology. It has been disputed among divines, whether the punishment of the wicked in a future world be strictly eternal or not. For the arguments on both sides of the question, see Hell.

Punitive Interest, in the Civil Law, such interest of money, as is due for the delay of payment, breach of promise, &c.

Punk, in Natural History, the inward part of the excellence or exuberance of an oak. It is used by the Indians in Virginia for medicinal burning, as the East Indians ufe moxa. Phil. Trans. No. 454. fed. 1.

Punn. See Pun.

Puno, in Geography, a town of Peru, now annexed to the vicerealty of La Plata or Buenos Ayres, and capital of a district of the same name, called also Pucarolla (not Pucarkerolla, as it is misprinted in that article). It is a rich and populous town, situated on the W. side of the lake Titicaca, and containing some illustrious families, as well as a beautiful church for the Spaniards, and another for the Indians, who weave great quantities of coarse cloth, with which they supply the neighbouring countries. S. lat. 16° 20'. W. long. 70° 26'.

Punt, in Sea Language, a sort of oblong flat-bottomed boat, with a square head and stern, whose floor resembles the platform of a floating stage; and used by shipwrights for blemming, caulking, or repairing a ship's bottom. It is also used in some canals.

Punta, in Geography, a town of South America, in the audience of Quito, and jurisdiction of Guayaquil.

Punta, La, a town of Mexico, in the province of New Biscay; 40 miles N.N.E. of Durango.

Punta is also an epithet, distinguishing several capes, which are too numerous to be here recited; and this is the Ues necessary, as the principal of them occur under other appropriate titles.

Punta Entornada, a town on the N. coast of Spain. N. lat. 43° 34'. W. long. 5° 32'.

Punta del Guada, a sea-port and capital of St. Michael, one of the Azores, defended by a castle.

Punta de Tordena, a town and cape of Spain, on the coast of Catalonia. N. lat. 41° 38'. E. long. 2° 37'.

PUNTO del Monte, a town of South America, in the province of Cordova; 15 miles S. of Cordova.

Punugga, a village of Bootan, situated in a deep hollow, and surrounded with mountains, for the most part covered with pines, along whose sides clouds are perpetually hovering. On the borders of this village are many large heaps of fir-leaves, which being left to ferment and rot, are used as excellent manure.

Pununagur, a town of Bengal; 10 miles W. of Nattore.

Punwary, a town of Hindoootan, in the circar of Gohud; 18 miles E. of Raat.

Puolango, a town of Sweden, in the government of Ulea; 46 miles S. of Cajana.

Pupa, in Natural History, a name lately substantiated in the room of chrysalis or aurelia, because: many insects in this state resemble an infant in swaddling clothes; and all, except those of the hemiptera order, take no nourishment. See Entomology.

Pupilio, in Geography, a town of Etruria; 10 miles N. of Pilcola.

Pupillus, Pupillus, in the Civil Law, a boy or girl not yet arrived at the age of puberty, i.e. under fourteen years of age for the boy, and under twelve for the girl.

While a minor remained under the direction of a tutor, he was called a pupil; after puberty, a curator being appointed him, he ceased to be called a pupil.

A tutor is obliged to pay interest for what monies of his pupil lie idle and unemployed. A tutor is allowed to do anything for his pupil, but nothing against him.

Pupil is also used by way of extension, in Universities, &c. in the sense of alumnus, for a youth under the education or discipline of any one.

Pupil, in Optics. It is observed, that as we are forced to use various apertures to our optic glasses, so nature has made a like provision in the eyes of animals, whereby to shut out too much, and admit sufficient light, by the changes in the aperture of the pupil.

The structure of the uvea and iris is such, that, by their aperture, the pupil is contrastible and dilatable at pleasure, so as to accommodate itself to objects, and to admit more or fewer rays, as the object, being either more vivid and near, or more obscure and remote, requires more or less light: it being a constant law, that the more luminous the object, the smaller the pupil; and again, the nearer the object, the smaller the pupil; and vis' estin.

This fact has been long ago noticed by optical writers.

B. Porta, about the middle of the sixteenth century, in his treatise De Refractione, p. 74, observes, that the pupil is contracted involuntarily when it is exposed to a strong light, and opens of itself when the light is small. A similar observation was made by his countryman and contemporary, Father Paul of Venice. Galen, indeed, first observed the dilatation of the pupil of one eye, when the other was shut or left, and the contraction of it, when the other was opened or recovered; and in this opinion he was followed by all naturalists and philosophers, till Fabricius ab Aquapendente, professor at Padua, by observing the eye of a cat, found
found that the pupil not only dilated and contracted itself, when one of the eyes was shut, but also when both were open. F. Paul found, from repeated experiments, that the pupil not only of cats, but also of men, and other animals, always contracted itself when the eye was exposed to a bright light, and again dilated itself when the light was faint and languid. This he always observed, as well when both eyes were open, as when one of them was shut. The same remark had been made by Achillinius, in a treatise published in 1522; and the fact was known to the Arabians, Rhazes and Avicenna. That the pupil of the eye is enlarged, in order to view remote objects, and that it is contracted while we are viewing those that are near, is a fact with which Scheiner, in the beginning of the seventeenth century, was well acquainted, and which he proved by experiments, and illustrated by figures. When a needle, or any small object, is brought near to the eye of any person, who looks attentively at it, the pupil, he says, is plainly seen to contract; and it as constantly expands whenever it is withdrawn.

This alteration of the pupil is effected by certain muscular fibres on the outside of the uvea, which arrive from nerves detached hither from the sclerotics. These fibres, proceeding straight from their origin towards the central periphery, in the orbicular limb or edge of the pupil, which consists of orbicular fibres, whereby the figure and space of the pupil are defined. The first, or longitudinal fibres, dilate the aperture of the pupilla; the latter, or orbicular ones, constrict it.

Some authors, however, attribute the motions of the pupil to the ligamentum ciliare; and others think, that both this, and the fibres of the uvea, concur herein. Dr. Derham adds, that while the pupil opens and shuts, the ligamentum ciliare dilates or compresses the crystalline, and brings it higher, or farther from, the retina, as the object is more or less remote.

There is no doubt that the change to which the pupil is subject is the effect of light upon the eye. Dr. Hartley, Obs. on Man, vol. i. p. 219, supposes, that the light which enters at the pupil has great efficacy in contracting both the greater and lesser rings of the iris, as may be concluded, he says, from the immobility of the pupil in a gutta serena; also because, on this supposition, the light which passes in at the pupil must, by contracting the lesser ring, become a check and guard against its own too free admission, which is agreeable to the tenor of nature in like instances. The retina, he observes, extends to the greater ring, and may send some nervous fibres to it, and even to the iris. Dr. Whytt also says, Essay on vital and involuntary Motion, p. 112, that the contraction of the pupil is not performed by the action of light upon the iris, but upon the retina; since whatever intercepts the rays of light, so as to prevent their reaching the retina, causes a preternatural dilatation of the pupil; because in a cataract, where the crystalline humour, being considerably opaque, intercepts a great part of the rays, the pupil loses a good deal of its contractile power. This author also observes, that the wideness of the pupil in a syncope, apoplexy, and confirmed gutta serena, shews that, in order to dilate the pupil to its largest size, no effort of the mind is necessary, but only the superior contractile power of the longitudinal fibres of the uvea, when its circular muscles is not excited into action by the stimulus of light on the retina. M. Mery informs us (Mem. Ac. Paris, for 1704) that, having plunged a cat in water, and exposing her eye to the strong light of the sun, the pupil was not at all contracted by it; whence he infers, that the contraction of the iris is not produced by the action of the light, but by some other circumstance. For he contends, that the eye in this situation receives more light than in the open air. M. de la Hire, in reply, endeavours to shew, (Mem. Ac. Par. for 1709) that fewer rays enter the eye under water, and that, in those circumstances, it is not liable to be affected by them. Besides, it is obvious to be remarked, that the cat must be in great terror in this situation; and being an animal that has a very great voluntary power over the muscles of the iris, and being now extremely attentive to every thing about her, she might have her eyes open, notwithstanding the action of the light upon it, and though it might be very painful to her.

The figure of the pupil, in various animals, is wonderfully adapted to their various circumstances and occasions: in some, e.g. in man, it is round, that form being fittest for the position of our eyes, and the various uses we make of them in all directions.

In others, it is elliptical or oblong: in some of which, e. g. the horse, sheep, ox, &c. the ellipse is transversely, and the slit large, to enable them to see laterally, and even with a little light; and thereby both to gather their food the better in the night, and to avoid dangers on either side.

In others, e. g. the cat, the ellipse is erect, and is also capable of opening very wide, and shutting very close, by means of the latter of which states, that animal can exclude all, but, as it were, a single ray of light, and so avoid all the inconveniences of the bright sun; and by the former, it can take in all the faintest rays, and thus avoid the inconveniences of the night: an incomparable provision for these animals, which are to watch and way-lay their prey both by day and night, to see upwards and downwards, to climb, &c. See Eye and Vision.

PUPIL Closer of. A preternatural smallness of the pupil always renders the patient incapable of discerning objects well at night-time, and occasions a diminution of vision. The consequence of a complete closure of the pupil, a cafe termed synopsia, is total blindness. These affections only differ from each other in degree, and they originate from the same causes. The most frequent cause is a violent inflammation of the eyes, particularly when such disorder extends to the iris, and arises at a period when the anterior and posterior chambers of the aqueous humour contain none of this fluid. This cafe principally happens after the extraction of the cataract. Here the inflammation constantly affects the capsule of the crystalline lens, so as to make it opaque, and at the same time adhere behind the pupil to the iris; a circumstance which is well deserving attention. Not unfrequently, however, a closure of the pupil takes place during ophthalmia, notwithstanding both chambers of the eye are full of the aqueous humour. Wounds of the iris sometimes cause this unpleasant occurrence, especially when they continue open, and do not heal. It is observed to be most frequently produced by such wounds as divide the radiated fibres of the iris transversely. These wounds, however, do not invariably remain open: sometimes they close, and then the pupil undergoes no alteration. Even when such wounds do not unite, a closure of the pupil does not always follow. In these instances, the natural pupil has been remarked to become closed, and the preternatural aperture in the iris to be widened, when the eye was exposed to the light; and, on the contrary, immediately the light was diminished, the pupil became dilated, and the other opening was contracted and closed. Wounds of the iris in the other direction, even when they remain diffused, often cause little or no diminution of the natural motion of the pupil.

It sometimes happens, that a greater or lesser portion of the iris is detached from the circumference of the cornea;
ternaturally dilated. In all such cases, the only indication is to endeavour to remove the original disease, of which the mydriasis is merely a symptom.

In the case where mydriasis is to be regarded as the only disorder, the complaint seems to depend upon a weakness or paralysis of the fibres which close the pupil. Here it is commonly the consequence of apoplexy, a blow on the eye, or a violent and sudden dilatation of the pupil, as, for example, sometimes happens in the extraction of a cataract. When the disease is of long standing, there is little hope of cure, whatever may be the cause from which the complaint arises. When it is recent, the pupil will sometimes regain the power of moving and contracting under the use of internal and external stimulating tonic remedies. The chief means of this class are, blisters applied to the eye-brows, ethereal oil rubbed into the skin around the orbit, electricity, emetic medicines in small and full doses, and other similar remedies, which are usually prescribed for the relief of paralytic affections of other parts. When these means prove unavailing, the practitioner must be content with recommending a palliative plan, which will be presently noticed.

As the pupil naturally dilates in the dark, it follows, that when a person is kept a long while away from the light, a mydriasis ex contractuadine is produced, the pupil becoming habituated to the expanded state, and losing the power of contraction. In most instances, it gradually recovers its motion after the eye has been for a certain time exposed to the light again. The light, however, must be allowed to get to the eye only by degrees, or else its sudden operation on the eye, in the expanded state of the pupil, would be apt to impair, or even destroy vision altogether. When the pupil does not recover its power of motion, the patient must be satisfied with resorting to palliative means. It has been remarked, that mydriasis is sometimes a congenital defect. All attempts at a radical cure must here be attended with extreme difficulty. When the light cannot be endured without inconvenience, the palliative plan is necessary. A blow on the eye sometimes tears the pupil. The rent moily remains open, and the patient is in the same state as if affected with mydriasis. Here, as the laceration cannot be repaired, the indication is to prevent, by palliative means, vision from being hurt by the too great strength of the light.

Through a preternaturally dilated pupil the light enters the eye in such quantity, that the patient is blinded. He not only sees things very indistinctly in light places, but he also runs a risk of being gradually entirely deprived of vision, in consequence of the too strong action of the light upon the eye. The prevention of such mischief is the object of the palliative treatment. By it the light which falls upon the eye is to be diminished, so that the patient may be enabled to see not only plainly and without inconvenience in light places, but also without any danger of losing his sight altogether. The usual means recommended for this purpose are, eye-shades, by which the light, coming principally from above, is kept from entering the eye; black veils over the face; green spectacles, which lessen the quantity of rays of light coming from objects which the patient is looking at; spectacles made with black cards, in the centre of which is left an opening of the size of the natural pupil. But the best and most proper means is a pair of tube-spectacles. This is a common place of spectacles, which, instead of glasses, has adapted to its two rings two conical tubes, the bases of which are to be put towards the eyes, and the narrower parts towards the objects which are looked at. These tubes ought to be made of black leather, and they should be three or four inches long. Their diameter at the base must be equal that of the circumference of the orbit; but their other ends need not be quite so wide. The edge of their bases is to be cut in such a way, that they will fit closely on the circumference of the orbit. The use of these spectacles consists in their keeping off all the rays of light coming laterally, and only admitting those into the eye, which proceed from objects in the axis of vision. Every surgeon will be able, according to circumstances, to multiply and vary the contrivance here described. See Richter's Anfangsgr. d. Wundartzneykunst, band 3, kap. 10.

PUPILLARIS MEMBRANA, in Anatomy, a circular membrane, by which the pupil is closed during the greater part of utero-gestation. See EYE.

PUPILLARITY, or PUPILLAGE, the state of a pupil; in opposition to puberty.

PUPPET, in Natural History. See AURELLA.

PUPPISOS, a name given by some authors to the os frontis. The future in this bone is also called by many anatomists the future puppis.

PUPPOLA, in Geography, a town of Sweden, in the government of Ulea; 45 miles S. of Ulea.

PUPULE, a name used by some to express the extremities of the fingers.

PUR, in Geography, a river of Russia, which runs into the Kazovskh gull. N. lat. 67° 40'. E. long. 78° 34'.

Pur autre vie, in our Law-Books, is used where lands are held for the life of another. See OCCUPANT, and TENANT.

PURA Elecmofyna, pure alms, denotes a tenure, whereby the churchmen hold lands in Scotland, somewhat on the footing of the primitive clergy.

Pura Hauja. See Hasta.

Puralla Bay, in Geography, a bay on the coast of Chili. S. lat. 42° 10'.

Purana, the common name of a series of poetical romances, confounded among the Hindoos as sacred works, the offspring of inspired writers, communicated for the instruction and benefit of mankind. They are ascribed, in their present form, to a celebrated man in the literary history of the Hindoos, whom they call Vyasa. (See VYASA.) He is supposed to have reduced an immense mass of inspired writings into eighteen works, and to have arranged them as they now appear. The following are the titles of these eighteen books, to which the common denomination of Purana is applied when spoken of or referred to. 1. Brahm, or the Great One. 2. Padma, or the lotos. 3. Brahmanda. 4. Agni, or fire. 5. Vifnu. 6. Garuda. 7. The transformations of Brahma. 8. Siva. 9. Linga. 10. Nareda. 11. Skanda. 12. Markandeya, or the immortal man. 13. Bhawhibya, or the prediction of futurity. 14. Madya. 15. Varaha. 16. Kurma. 17. Vamana. 18. Bhagavata. Of these, the first four relate to cosmogony; the next nine to the attributes and powers of the Deity. The sixth is named after the vehicle or bird of Vifnu, called Superna, as well as Garuda. (See SUPERNA.) See LINGA, for the mysterious symbol whence the ninth derives its name. Nareda, whose laws and history are detailed in the tenth, is a mythological son of Brahma. Skanda, the hero of the eleventh, is a name of Karitika; see that article. The fourteenth and three following relate the histories of four of the principal incarnations of Vifnu the preserver, called Madya Tatarva, Varakavatara, Kurmakavatara, and Suvama-

Vatara. Under these articles respectively will be found a brief notice of the outline of their histories. The eighteenth, called Sri Bhagavata, is the life of Krishna, (see KRISHNA), with
with which the poet Vyasa is popularly imagined to have crowned the whole series; though some reasonably assign them different composers; and the series is differently arranged and named by other authorities. Every Purana treats of five subjects. 1. The creation of the universe. 2. Its progres, and the renovation of the worlds. 3. The genealogy of gods and heroes. 4. Chronology, according to a fabulous fable. 5. Heroic history, containing the achievements of demigods and heroes. Since each Purana contains a cufumory, with mythological and heroic histories, they may, not unaptly, be compared to the Grecian theogonies.

A copy of, we believe, all the eighteen mythological poems, is preserved in the library of the East India house. It is estimated that the whole cannot consist of less than half a million of flessas. Hitherto no translation of any of them, or of any considerable portion of either, hath been made from the original into any European language. They are, of course, written in the Sanscrit tongue. In some articles of this work a flessa, or a brief outline of some of the Puranic tales, elucidatory of the character or subjeét under discussion, is occasionally introduced, and may perhaps give some little idea of the style of these extravagant poems. The reader, in this view, may consult the following, in addition to the other articles herein and thence referred to; JAM-BAVANTA, KALPA, KARSHAGNI, KRITIKA, LILESWARA, LOTOS, MERTU, MUNI, NAKSHATRA, NARAMEDHA, PA-VAKA, PAVANA, PIKESWARI, POLLEAR, PRITHU, &c. &c

As to these extravagant, and not always decent, tales of the Puranas, the probability is that physical or historical facts are thus connected under a veil of allegory, carried through a series of poetical narratives and adventures, related of the personified attributes of the Deity. The facts are either forgotten, or unknown to the vulgar; but the fables remain, and are generally and commonly alluded to in composition and conversation. Taken literally, as the transmutations of divine or holy persons, nothing (bating the invention, imagery, and other poetic merits) can be more contemptible than these Puranic romances; but if we desire to extract the grains of ore that the malts may probably contain, we must be content to examine them as they are; and in case of failure, many inquisitive researchers will deem their labour not lost, in the invention and other poetical beauties abounding in theses wild compositions.

We shall briefly give an abstract of the contents of two or three of the Puranas, whence a judgment may be formed of the others. The Agni Purana is entitled to have been delivered by Agni, or Pavaka, the god of fire. (See Pa-VAKA.) It contains a great variety of subjects, and seems to have been intended as an epitome of Hindu learning. The poem opens with a short account of the several incarnations of Vishnu, an enumeration of which, with a brief outline of their history, will be found in the article VISHNU of this work, and thence referred to. It dwells, however, chiefly on the incarnations of KRITIKA and RANA. (See these articles.) Then follow a history of the creation; a tedious dissertation on the worship of the gods, with a description of their images, and directions for constructing and setting them up; a concise description of the earth, particularly of those places which are exalted holy, with the forms of worship to be observed at them; a treatise of astronomy, or rather astrology; a variety of incantations, charms, and spells, for every occasion. One species of this is named mantras, under which article a sufficient account is given of them; computations of the periods called MANVASANTRA, KALPA, &c. (See KALPA); a description of the several religious modes of life called aYRAMA, and the duties to be performed in each; rules for penance (on this head see TAPAS); feasts and fasts to be observed throughout the year; rules for bellsowing charity; a dissertation on the great advantages to be derived from the mystic word OM (under which article of this work the reader will probably find sufficient of mysticism), with a hymn to Varuna, of whom something occurs under that article. The next head relates to the office and duties of princes; under which are given rules for knowing the qualities of men and women; for choosing arms and emblems of royalty; for the choice of precious stones; and a treatise on the art of war. The next head treats of worldly transactions between man and man, as to buying and selling, borrowing and lending, giving and receiving, &c. &c. Then follow certain ordinances, according to the Veda, respecting security from misfortunes, &c. and for the worship of the gods. Genealogies of the two races of solar and lunar kings, called Suryavansha and Chandravansha (see SURYA); of the family of Yadu and of Krishna, with a short history of the twelve years war, described in the Mahabarat. (See MAHABARAT.) A treatise on the art of healing, as applicable to man and beast, with rules for the management of elephants, horses, and cows; charms and spells for curing various disorders; and the mode of worshipping certain deities; on the letters of the Sanscrit alphabet; on the oraments of speech, as applicable to oratory, poetry, and the drama; on the mystic significations of the single letters of the Sanscrit alphabet; a grammar and short vocabulary of that language. The whole of this defuluary work is divided into 353 short chapters.

The Siva Purana is sometimes called also, after one of the forms of his comfort, the Kalika Purana. (See KALI.) It is a mythological history of that goddes, including her adventures under various names and characters. Many of those names and characters are enumerated under the article PARVATI, her more common name; and Mr. Moor has given an extract under Naramedha, which word means a man-sacrifice, the rites and ceremonies of that horrid offering being minutely laid down in this Purana. It is a curious and entertaining work, including as episodes several beautiful allegories, particularly one founded on the motions of the moon. See Moor's Hindu Pantheon.

The Vayu Purana, as one of these poetical romances is variously called, but which we have not the means at this moment of ascertaining, is attributed to the regent of wind Vayu, otherwise and more commonly called Pavana (see PAVANA); where the reason is furnised why the Purana is not called after that name. It contains, among a variety of other curious subjects, a circumstantial detail of the creation of all things, celestial and terrestrial, with the genealogy of the first inhabitants; chronological computations as to the grand periods MANVASANTRA, KALPA, &c. before spoken of; a description of the earth, as divided into islands, continents, &c. and its dimensions, and also of other planets and fixed stars, their distance, circumference of orbits, &c. &c. Under the article PAVANA, an extract is given from the Matya Purana, directing how images or pictures are to be made of the god of wind. Most of the Puranas contain directions of that sort.

A brief notice of one other of these inspired works will suffice. The Nareda Purana is believed to have been delivered by the inspired Nareda, a mythological son of Brahma. Under the article NAREDAS (see Hindu Pantheon) an account is given of him, with his genealogy, and the derivation of his name, from the Varaha Purana. Like the others, this poem opens with describing "how heaven and earth rose out of chaos;" but it treats principally of the unity of God, and as it fectiorally is written with the Vaiṣhṇava bias (see VAIŚH-NAVAYA).
PURBAH, George, in Biography, an eminent mathematician and astronomer in the 15th century, was born at Purbach, a town on the confines of Austria and Bavaria, in 1423. He was educated at Vienna, where he manifested great talents, and took his degree of M.A. with great applause. He directed his attention principally to mathematics and advanced in that science with almost incredible rapidity. For farther improvement, he visited the most celebrated universities of Germany, France, and Italy. He found a particular friend and patron in cardinal Cusa, and he formed an intimacy with John Blanchini of Bologna, who admiring Purbach's extensive knowledge, and his ready method of communicating instruction, wished to prevail upon him to deliver lectures on astronomy at Ferrara; but Purbach preferred returning to Vienna, where he obtained the mathematical professorship in that university. About this time he received offers from Ladislaus, king of Hungary, to become his astronomer, accompanied with promises of liberal rewards and distinguished honours, which he declined.

The fame of Purbach, as a mathematical professor, was soon widely diffused, and brought numerous students to attend his lectures at Vienna. Among others was the celebrated Regiomontanus, who secured the esteem of his master, and was chosen the aifente and companion in his labours. From this time they maintained an union of studies, in their endeavours to improve the different branches of mathematical science, and more particularly astronomy. This science they would, no doubt, have materially improved by their joint labours, had Purbach's life been prolonged. His first essay was to amend the Latin translation of Ptolemy's Almagest. After this he wrote "An Introduction to Arithmetic," and proceeded to draw up another "On Gnomonics," or dialling, with tables suited to the difference of climates and latitudes. This was followed by a small tract "Concerning the Altitudes of the Sun," with a table, and "Astronomic Cansons." After this he made solid spheres, or celestial globes, and not only explained their construction and uses, but added to them a new table of fixed stars, with the longitude by which every star had increased, from the time of Ptolemy to the middle of the fifth century. He also invented various other instruments, among which was a "gnomon," or geometrical square, with canons, and a table for the use of it, which he sent to the archbishop Strigonia, who was himself a man of great erudition, and entertained a high opinion of Purbach. Our author made considerable improvements in trigonometry; prepared tables of the fixed stars, and undertook to reform those of the planets, and constructed some entirely new ones. When these tables were finished, he drew up a kind of perpetual almanack, chiefly for the moon, answering to the periods of Meton and Calippus: also an almanack for the planets, or, as it was afterwards called, an Ephemeris for many years. He finished his "Theorie Noue Planetarum," (see Muller,) which was made a textbook in all the schools, and was commented upon by some of the most eminent mathematicians. Purbach died in the 38th year of his age, in 1451.

PURBECK, Isle of, in Geography, a district in the Blandford division of the county of Dorset, England, is bounded on the west by Luckford lake; on the south by the British channel; and on the other side by the river Frome, and the bay of Poole. It is improperly called an island, being in fact only a peninsula, as it may be entered from Earl Gulworth by an isthmus, between the head of Luckford lake and the sea. This district extends twelve miles in length, and varies from leven to ten in breadth.
It includes two hundreds, called Hazler and Rowbarrow, the former comprehending the eastern division of the island, and the latter the western. These are subdivided into nine parishes, and contain one town, Corfe-caitle, and several large villages and hamlets. The soil is everywhere calcareous; but the surface is much diversified by hill and dale. The quarries, towns, and cliffs, on the south side of the island in particular, afford an inexhaustible fund of natural curiosities. Near Kingston, Worth, Langton, and Swanwick, are extensive quarries of freestone; and in many parts is a flone that rifies thin, and is used for tilting; also a hard paving stone, much of which was used in rebuilding London after the fire, and in paving the streets and courts. At Swanwick is a white flone full of shells, which takes a high polish, and looks like alabaster; and near Dunby is dug up marble of various colours, but chiefly a grey kind, formed by a congeries of shells, and anciently much used for grave stones and monuments. It was likewise very generally employed for small columns in the churches which were erected during the 13th century. The corina amonos are frequently discovered here, some of them two or three feet in diameter.

In ancient times the whole of this island was a forest, and was well stocked with red and fallow deer, and flags, especially in the west parts; but these were almost entirely destroyed in the civil wars. James I. was the last of our kings who hunted here. The whole island was till lately governed by a lord-lieutenant, who was admiral of the island, and had power to raise and muster a militia; but this office ceased when the regular militia act was passed. Formerly there were many gentlemen's seats dispersed all over the island; which were probably built for the reception and accommodation of the nobility and gentry who attended the royal hunts, as most of the owners of estates in this part of the country had their principal seats elsewhere, and only came hither in the hunting feasons. These are now almost, without exception, converted into farm-houses. For an account of the only town in Purbeck, see Corfe-Castle.

Purbeck Stone, the faxum arenarium cimereum Purbeckens of Da Colta, and psdarium frabili albo fucum of Hill, is an alkaline sand-flone, which is hard and rough, of a disagreeable ahen colour, very heavy, and moderately hard, of a texture not very compact, but somewhat porous, and is composed of an angular grit, cemented together by an earthy spar: it cuts freely, and with a tolerable even or smooth surface, but will not take a polish. It will not strike fire with a steel, and burns white a yellow colour. The quarries of this flone are in the ifland of Purbeck, in Dorsetshire, whence it is brought to London in great quantities, and used in building, and for pavements. Its specific gravity is 2.68. There is another kind of Purbeck Rone, the faxum fucem-albidum of Da Colta, and the symposium durifimum, splendidum albo-fucem of Hill, which is alkaline, of a dull, disagreeable, pale, brownish, white colour, and is not capable of a polish, though it cuts to a very smooth surface: it is of a fine, close, compact texture, not quite deftruite of brightnes, but full of sparses of pure spar, and intimately mixed with salt quantities of small pealcinctum, which are often faurate and filled with the fame substance: it is very heavy and hard, and water does not pervade its texture; it does not strike fire with steel, and when burnt acquires a clear ahen colour. This flone is brought from Purbeck, and used in building, pavements, &c. Hill informs us, that it is likewise found in many other parts of the kingdom, and that there are large strata of it in Yorkshire. Da Colta's Fossilis, p. 128-152.

Purburry, in Geography, a river of Hindooftan, which runs into the Chumbul; seven miles W. of Sultapour, in the country of Agimere.

Purcar, a town of European Turkey, in Baffarabia, on the Dnieter; 4 miles S.E. of Bender.

Purcell, Henry, in Biography, an English musician of more extensive genius than perhaps our country can boast at any other period of time, was born in 1659. His father, Henry, and uncle, Thomas Purcell, were both musicians, and gentlemen of the chapel royal, at the restoration of King Charles II. There is a three-part song in Playford's "Musical Companion," by Henry Purcell, which, being printed in 1667, when our great musician was but nine years old, must have been the production of his father. There is likewise a chant in the first volume of Boyce's Collection, p. 289, No. II. called the "burial chant," by Thomas Purcell, his uncle, who continued in the service of the chapel till the time of his death, in 1682. Though these compositions promise no great hereditary genius, they are mentioned here, as mankind is naturally curious concerning every thing that is connected with eminent persons.

From whom Henry received his first instructions in music, cannot be very clearly ascertained. But his father dying in 1664, when he was no more than six years old, it is probable he was qualified for a chorister by Capt. Cook, who was master of the children from the restoration till the time of his death, in 1672. For, as Purcell was appointed organist of Westminster Abbey at eighteen years of age, he must have learned the elements of his art before his fourteenth year, at which time Pelham Humphrye, brought up in the royal chapel under Capt. Cook, was appointed his successor, as master of the boys. Purcell certainly continued to sing in the king's chapel, and to receive lessons from Humphrye till his voice broke, an accident which usually happens to youth at sixteen or seventeen years of age: after this, perhaps, he had a few lessons in composition from Dr. Blow, which were sufficient to cancel all the instructions he had received from other masters, and to occasion the boast inferred on the tomb-stone of Blow, that he had been "Master to the famous Mr. Henry Purcell."

But there is nothing more common than this petit larceny among musicians: if the first master has drudged eight or ten years with a pupil of genius, and it is thought necessary, in compliance with fashion or caprice, that he should receive a few lessons from a second, he instantly arrogates to himself the whole honour, both of the talents and cultivation of his new scholar, and the first and chief instructor is left to sing, sic vos non vocis.

Purcell is said to have profited so much from his first lessons and clofe application, as to have composed, during the time of his being a finging boy in the chapeL many of his anthems, which have been constantly sung in our cathedrals ever since. Eighteen was a very early age for his being appointed organist; that is, maestro di capella of Westminster Abbey, one of the first cathedrals in the kingdom for chorale compositions and performance. It was not likely he would stop here: the world is, perhaps, more partial to promising youth than accomplished age; and at twenty-four, in 1682, he was advanced to the post of organist of the chapel royal, on the death of Edward Low, the successor of Dr. Christopher Gibbons, in the same situation.
After this, he produced so many admirable compositions for the church and chapel of which he was organist, and where he was sure of having them better performed than elsewhere, that his fame was soon extended to the remotest parts of the kingdom.

From this time, his anthems were eagerly procured, and heard with pious rapture wherever they could be performed; nor was he suffered long to devote himself totally to the service of the church. He was, very early in life, solicited to compose for the stage, and chamber, in both which undertakings he was so superior to all his predecessors, that his compositions seemed to speak a new language; yet, however different from that to which the public had been long accustomed, it was universally understood. His songs seem to contain whatever the ear could then wish, or heart could feel.

We have been assured by a very good judge of music, who was nineteen years of age when Purcell died, and remembered not only his person very well, but the effect which his songs had on himself and the public at that time, when many of them were first heard; and used to say, that "no other vocal music was listened to with pleasure, for near thirty years after Purcell's death; when they gave way only to the favourite opera songs of Handel."

The unlimited powers of this musician's genius embraced every species of composition that was then known, with equal felicity. In writing for the church, whether he adhered to the elaborate and learned style of his great predecessors Tallis, Bird, and Gibbons, in which no instrument is employed but the organ, and the several parts are constantly moving in fugue, imitation, or plain counterpoint; or, giving way to feeling and imagination, adopted the new and more expressive style of which he was himself one of the principal inventors, accompanying the voice-parts with instruments, to enrich the harmony, and enforce the melody and meaning of the words, he manifested equal abilities and resources. In compositions for the theatre, though the colouring and effects of an orchestra were then but little known, yet as he employed them more than his predecessors, and gave to the voice a melody more interesting and impassioned than, during the seventeenth century, had been heard in this country, or perhaps in Italy itself, he soon became the darling and delight of the nation. And in several species of chamber music which he attempted, whether litanies for interludes, canzonets, orodes, sonatas, fantasias, ballatas, or for the voice, he so far surpassed whatever our country had produced or imported before, that all other musical productions seem to have been instantly confounded to contempt or oblivion.

As many of his numerous compositions for the church, particularly those printed in the second and third volumes of Dr. Boyce's Collection, are still retained in the king's chapel, and in our cathedrals, we shall here acquaint the musical reader in what manner we have been affected by some of these productions, in a late attentive perusal of them. It appears by Dr. Bayley's "Collection of the Words of Anthems used in his Majesty's Chapel Royal," that ten of Purcell's are still performed there; and in the late Rev. Mr. Mafon's "Copious Collection of the Words of such Anthems as are used in the Cathedral of York," that nearly twenty of his choral compositions are still sung in that choir.

Purcell's four-part anthem, "O God, thou art my God," (Boyce's Collection, vol. ii. p. 148.) must certainly have been one of his juvenile productions, before he had sufficiently refined his ear, or exercised his judgment; as there are many crude harmonies, and false accents in it, which in riper years he would not have tolerated.

Of his four-part anthem, "O God thou hast call us out," the first movement, in which there are many bold harmonies, is extremely elaborate, yet spirited and pleasing. The verse, "O be thou our help," is not only full of new and fine effects, but touching. By those who object not to the confusion in the words which arises from fugue and imitation, while the several parts are sounding different portions of the same sentence, at the same time, the words will appear perfectly well accented and expressed.

The first movement of his full anthem in eight parts, "O Lord God of hosts," is a noble composition, *Alta Puraus*, in which all the laws of fugue are observed, and sometimes more subjects, are preferred inviolable; the harmony, though bold, is, in general, chaste; and the effect of the whole spirited and majestic. The second movement is extremely pathetic and expressive; but, both in that and the last movement, he seems trying experiments in harmony; and, in hazardizing new combinations, he seems now and then to give the ear more pain than pleasure.

The two-part anthem, "Thy way, O God, is holy," continues to be excellent music still, in the slow movements; the quick, however, seems somewhat antiquated, and the melody to these words, "the air thundered," &c. seem too light and dramatic for the church at any period.

The three-part anthem, "Be merciful unto me, O God," is admirable throughout. Indeed, to our conceptions, there seems no better music existing, of the kind, than the opening of this anthem, in which the verse, "I will praise God," and the last movement, in C major, are in melody, harmony, and modulation, truly divine music.

The complete service of Purcell, in B flat, printed by Boyce, is a most agreeable and excellent piece of counterpoint, of which the modulation frequently surprises attention by unexpected transitions, yet of so sober a kind as never to give the ear the least uneasiness, till we come to the bottom of p. 110, and then the same crudities of the harp 3d and flat 6th, and flat 5d, 4th, and 5th, which we have already noticed in the works of Dr. Blow, occur; which we hope, in spite of our partiality for Purcell, the organists of our cathedrals scruple not to change for better harmony.

These two or three combinations, like some words and phrases which Shakspere tried unsuccessfully to render current, have been rejected by posterity; and it is in vain to attempt at forcing them upon the public by the mere weight of authority. The ear will patiently bear every rough usage from an artist who in general makes it such ample amends; however, there are limits, beyond which it is unsafe to exceed cruelty of all kinds; and the auricular sense will be deadened, disgust, or rendered indifferent to music's powers, by too harsh treatment.

The "Benedictus," as well as "Te Deum," and all the rest of the service, must be extremely pleasing, in all other respects, to every ear sensible to harmony. The words are, in general, accented with great accuracy (except the contracting height into a monolythical, to which only one note is given); and the few points of imitation are fragments of agreeable melody. In p. 121 of Boyce, the A 5, at the word *beasts*, in the Kyrie, are peculiarly beautiful, as are the 9th with the 9th at "before all worlds," in the creed, and the close at "by whom all things were made." The point at "throughout all generations," in the Magnificat, is what the Italians call *tenorato*, well-worked. In the last line, however, of page 132, so many exceptional combinations
nations occur, that we cannot pass them over without a digression. Yet, upon the whole, the abilities of Purcell, as a profound contrapuntist, appear perhaps more in the course of this service than elsewhere; as he has manifested deep study and meditation in a species of writing to which it was not likely that his creative and impetuous genius would submit, having had the patience, as well as abilities, to enrich it with no less than four different canons, of the most difficult construction, as of two, three, and four in one, by inversion.

The superior genius of Purcell can be fairly estimated only by those who make themselves acquainted with the state of music previous to the time in which he flourished; compared with which, his productions for the church, if not more learned, will be found infinitely more varied and expressive; and his secular compositions appear to have descended from another more happy region, with which neither his predecessors nor contemporaries had any communication.

Besides the whole service, with three full, and six verse anthems, in Dr. Boyce’s Collection, there are nine verse and full anthems, wholly different, still sung in the cathedral at York. And in Dr. Tudway’s Collection, British Museum, there are besides a whole service in B flat, different from that in Boyce, eight full and verse anthems, different from all the rest, four of which were composed for the chapel royal of Charles II., and are accompanied with instruments. And still, exclusive of these and the hymns printed in the two books of “Harmonia Sacra,” in a manuscript bequeathed to Chrift-church college, Oxon. by Dr. Aldrich, there are two motets, and a “Gloria Patri” for four and five voices, in Latin, with seven psalms and hymns for three and four voices, by our fertile and diligent composer, that have all their peculiar merit, but of which none may, without hyperbole, be said to reach the true sublime of sacred music.

To enter into a minute examination of these, and his admirable Te Deum and Jubilate, composed for St. Cecilia’s day, 1694, would extend this article to too great a length; though they merit much praise as well as critical remark; for which, on the Te Deum we refer our readers to the ample account of him and his works, in Burney’s History of Music, vol. iii.

Purcell’s theatrical compositions, if we collect the number and excellencies of his productions for the church, and the shortness of his life, will surmise by their multiplicity as well as inorganic merit. Of these dramas which are called operas, and of which music and decorations were the principal allurements held out to the public, a detailed account is given in speaking of the origin and progress of the musical drama in England, previous to the use of the Italian language, music, and performers on our lyre stage. (See Masques, and Matthew Locke.) And of Purcell’s detached and incidental songs, dialogues, and fancies that were performed at our national theatre, or playhouse, the principal will be mentioned in speaking of his “Orpheus Britannicus,” or posthumous collection of his miscellaneous compositions. But before we enter on an examination of this work, it seems necessary to acquaint the reader, that the chief part of his instrumental music for the playhouse is included in a publication that appeared two years after his decease, under the title of “A Collection of Ayres composed for the Theatre, and on other Occasions, by the late Mr. Henry Purcell,” London, printed for Frances Purcell, Executrix of the Author, 1697.” These airs are in four parts, for two violins, tenor, and basso, and were played as overtures and air-tunes in our own memory, till they were superceded by Handel’s hautbois concertos, and those, by his overtures, while Boyce’s sonatas, and Arne’s compositions, served as air-tunes. In process of time these were supplanted by Martini’s concertos and sonatas, which were thrown aside for the symphonies of Van Mulder, and sonatas of the elder Stamitz. About this time, the trios of Campioni, Zanetti, and Abel, came into play, and then the symphonies of Stamitz, Canabich, Holtzbauder, and other Germans, with those of Bach, Abel, and Giardini; which, having done their duty many years very pleasantly, “slept with their fathers;” and at present give way to Vanhall, Boccherini, Haydn, and Pleyel. “Sic transit gloria muclicorum!”

Purcell seems to have composed introductory and air-tunes to most of the plays that were brought on the stage during his time. The publication of these, in four parts, contains his music to the following dramas:

“Abelazor,” 1677. The music of this consists of an overture, and eight airs or tunes.

“India’s Queen.” The first movement of this overture is equal to any of Handel’s. There are likewise two or three trumpet-tunes, well calculated for the instrument, and a rondeau at the end, which would now seem new, if played in a concert by a good band.

“Dido and Aeneas,” or the “Prophetessa,” 1690. The instrumental music of this English opera given here, consists of an overture of two movements, the first excellent in the style of Lulli, and afterwards of Handel, with better fugues; prelude, accompaniment to a song, trumpet-tune, air, hornpipe, country-dance, and canaries.

“Amphitryon,” 1691. Overture and eight tunes.

“Gordian Knot untied,” 1691. Overture and seven tunes.

“Dilressed Innocence, or the Princes of Peria,” 1691. Overture and seven tunes, all proofs of the author’s original genius.

“The Fairy Queen,” 1692. Two overtures and sixteen tunes of different kinds. N° 12, an air, 4 in 2, is a very curious canon on two subjects: the first treble and bafe performing one, and the second and tenor the other. There is as much accent and spirit in this composition, as if it were in free counterpoint.

“The Old Bachelor,” 1693. Overture and eight tunes.

“The Married Beau,” 1694. Overture and eight tunes, among which is a very agreeable air for the trumpet, a march, and hornpipe, that are characteristic. This last is very much in the style of a Spanish fandango.

“Bondoça,” 1695. Overture and eight tunes, including “Britons strike homes,” and “To arms,” in four parts. These are the contents of this posthumous publication; but besides the music for these dramas, he composed overtures, air-tunes, and songs, for “Timon of Athens,” 1678; for “Theodorus, or the Force of Love,” 1680; for Dryden’s “Tempest,” 1694; and for “Don Quixote,” 1694.

But few of Purcell’s single songs seem to have been printed during his life. He published the music to a masque sung in the tragedy of “Oedipus,” when it was revived in 1694. And “a musical entertainment, performed Nov. 22, 1683, on St. Cecilia’s day, printed in score by John Playford, with a dedication to the gentlemen of the musical society, and particularly the stewards, written by Henry Purcell, composer of the music.”

D 2
PURCELL.

There are several of his songs in Playford's Collection, called "The Theatre of Music, 1687, fourth and last Book," and though these are not in his best manner, they are more original and interesting than the rest. Among these is a "New song to a Scotch tune," by our author, of which we may use more pleasing and less hidden, than any of the Scotch songs, or imitation of the national melody of the northern inhabitants of this island, that has been since produced.

Page 62 of the same Collection, there is an admirable piece of recitative, in a truly grand style: "Amidst the shades," &c. But the collection of his secular vocal music, which did him the greatest honour, and long rendered his name dear to the British nation, was published by his widow two years after his decease, by the title of "Orpheus Britannicus." Here were treasured up the songs from which the natives of this island received their first great delight and impression from the vocal music of a single voice. Before that period we had cultivated madrigals, and songs in parts, with diligence and success; but in all these songs, and thofe of Purcell appeared, the chief effects were produced from the words, not the melody. For the airs, till that time, were as unformed and mis-shapen, as if they had been made of notes scattered about by chance, instead of being cast in an elegant mould. Exclusive admiring of modern symmetry and elegance, may call Purcell's taste barbarous; yet in spite of superior cultivation and refinement, in spite of all the vices which of fashion, through all his rudenesses and barbarisms, original genius, feeling, and passion are, and ever will be, discoverable in his works, by candid and competent judges of the art.

To this admirable collection are prefixed seven copies of verses to his memory, at the head of which is an ode, written on his death, by Dryden, which was set by Dr. Blow, and performed at the concert in York Buildings.

There are few songs in the "Orpheus Britannicus" but what contain some charactetistic marks of the author's great and original genius. The melody, however, will at first seem to many at present uncouth and antiquated; but by a little allowance and examination, any one pleased of a great love for music, and a knowledge of our language, will feel, at certain places of almost every song, his superior felicity and passion in expressing the poet's sentiments which he had to translate into melody.

The favourite songs with Purcell's admirers in our youth, were the following; and upon a late attentive perusal of the book, they seem to have merited particular distinction.

"Celia has a thousand charms:" the first movement of this, like many of Purcell's songs, seems only recitative, or embellished with the fashionable volatil, or flourishes of the tunes, which are now as antiquated as the curls of his own peruke, or the furbelows and lincees of Queen Elizabeth. The second movement, however, of this song is plaintive and graceful; and at "I should my wretched, wretched, fate deplore," is still new and pathetic.

"You twice ten hundred duties," opens with what seems to us the best piece of recitative in our language. The words are admirably expressed throughout this song, by modulation as well as melody. And there is a propriety in the changes of movement, which does honour to Purcell's judgment, as much as the whole composition to his genius. The change of style and sluggish motion given to the notes at these words, "from my sleeping mantling rife," is a model of musical imitation and expression. The modulation is still so excellent, that the best modern masters are obliged to adopt it on almost all great occasions.

"O of the music to "King Arthur" we shall lay but little, as it has been lately revived, well performed, and printed. If ever it could be laid with truth of a composer, that he has been "for a century," outstripped his age, Purcell is entitled to that praise; as there are movements in many of his works which a century has not injured, particularly the duet in King Arthur, "Two daughters of this aged Kent," and "Fairest isles of isles excelling," which contain not a single passage that the best composers of the present times, if it presented itself to their imagination, would reject. The dialogue in the "Prophetess," "Tell me why, my charming fair," is the most pleasing and ingenious of all the compositions of the kind which the rage of fashion produced during fifty years. The first part of "O lead me to some peaceful gloom," is truly elegant and pathetic.

"From roie bow's," is laid to have been "set in his last sicknels," at which time he seems to have realized the poetical fable of the fawn, and to have sung more sweetly as he approached nearer his dilution; for it seems to us, as if no one of his productions was so elevated, so pleasing, so expressive, and throughout so perfect, as this. The variety of movement, the artful, yet touching modulation, and, above all, the exquisite expression of the words, render it one of the most affecting compositions extant to every Englishman who regards music not merely as an agreeable arrangement and combination of sounds, but as the vehicle of sentiment, and voice of passion.

There is more elegant melody, more elaborate harmony, more ingenious contrivance, in the motion and contexture of the several parts than in the works of many great composers; but to the natives of England, who know the full power of our language, and feel the force, spirit, and shades of meaning, which every word bears according to its place in a sentence, and the situation of the speaker, or finger, we must again repeat it, this composition will have charms and effects, which, perhaps, Purcell's music only can produce.

"When Mirra sings," is a duet that will ever be captivating, as long as the words remain intelligible; of which he has augmented the force, particularly at the end, by notes most select and expressive that the musical scale can furnish.

"Loft is my quiet," another duet, which still lives. And "Celebrate this festival," a birthday song for Queen Mary, which is graceful and pleasing through all its old-fashioned thoughts and embellishments. "I'll fall upon the dog-star," has all the fire of Handel's prime.

"Mad Bfs" is a song, or rather a cantata so celebrated, that it needs no panegyric, or renewal of public attention, as every captivating English singer in our memory has revived its favour. The first Mrs. Sheridan and Mrs. Bates never gave more exquisite delight by their admirable performances, than when they rejoiced their friends with this song. Beard, forty years ago, used to acquire great applause by singing Purcell's "Rosy Bowers," and Paffy, by her performance of "Mad Bfs," in the concerts at Hickford's rooms, the Castle, and Swan concerts, where Stanley was justly admired for his ingenious and masterly manner of accompanying them. "The Nature's Voice," is an etymological song, feemingly on nature, in which Purcell has crowded all the fashionable graces of taste and vocal difficulties of the time. Indeed, he seems to have anticipated many fantatical feats of execution and articulation in which great performers have since rivalled; and this is the more wonderful, as the Italian opera was not established, or even attempted here, during the life of Purcell; whose decease preceded the arrival of Valentini and Nicoli, the first great singers imported from Italy, at least ten years.

"Blow,
"Blow, Boreas, blow," was in great favour, during our youth, among the early admirers of Purcell; but this seems now more superannuated than any of his popular songs.

"Let Caesar and Urania live," was a duet in a birth-day ode, during the reign of king William and queen Mary, which continued so long in favour, not only while those fore-reigns jointly wielded the sceptre, but even when George II. had lost his royal comfort, and there ceased to be a queen, or Urania, for whom to offer up prayers, that Dr. Green, and afterwards Dr. Boyce, used frequently to introduce it into their own and the laureate's new odes. This duet, like many other productions of Purcell, was built on a ground-bafe of only two bars, which are invariably repeated to different passages of the voice-parts that are in harmony with it, throughout the movement. The latter part of this duet is extremely beautiful, and does not seem at all to have suffered from the voluntary restraint under which the composer laboured.

The composing songs on a ground-bafe, was an exercise of ingenuity, in which Purcell seems to have much delighted; but though it was as much a fashion in his time, as the composing madrigals on the subjects of old tunes in the days of Juquin, and variations upon those tunes in the days of Bird and Dr. Bull, in which they all manifested superior abilities, yet the practice was Gothic, and an unworthy employment for men possessed of such genius and original resources. The Italians started this, as well as most other musical fashions; for it appears by the works of Tranquino Merula, published 1635, that writing upon a ground-bafe was a favourite occupation with that capricious composer, as well as our ingenious countryman.

Judges of musical design, modulation, and expression, will meet with many places to admire in songs that have never been popular, yet have local beauties, and mark the superior powers of the composer; particularly in the "Sigis for the death of king Charles II." In the "Dialogue in tyrannic Love," p. 158, there is a passage upon which the late Mr. Bach has constructed a favourite movement in one of his Quartetti concertanti.

"I attempt from love's sicknees," is an elegant little ballad, which, though it has been many years dead, would soon be recalled into existence and fashion, by the voice of some favourite singer, who should think it worth animation.

"Let the dreadful engines!" this is the last song in the first volume of the "Orpheus Britannicus," of which, though both the words and music of the first movement are wild and bombast, yet the second and last discover a genius for the graceful comic, as well as the tender and sublime style of composition; and there are several passages in this cantata sufficiently gay and new for a modern burletta.

In 1702, a second, and more correct, edition, of the first volume of this work was published, with more than thirty songs that were not in the first impression; but, in order to make room for which, some of the former were excluded.

The same year was likewise published a second volume of "Orpheus Britannicus," by Henry Playford, which he dedicated to the earl of Halifax. The song of this second volume, p. 4, beginning, "Ah! cruel nymph!" has great ingenuity in the first movement, and grace in the second. And the next air, "Crown the altar," seems the most pleasing of any that he has composed on a ground-bafe. "May the god of wit inspire," for three voices, is natural and pleasing, and the echoes in the second part are very ingeniously contrived.

"Thus the gloomy world," accompanied with the trumpet, and violin alternately, is masterly, and well designed to display the truest and most brilliant tones of the trumpet, though but little is given to the violin, which so much better deferves employment, than an instrument of such false intonation as the trumpet.

Those that can relish good music of every age and country, and have no exclusive partiality to individuals of either, will find amusement in the performance or perusal of Purcell's "Four Sea-songs," in the "Fairy Queen," which comprehend merit of various kinds.

"To arms, to arms," is an admirable military song, accompanied by a trumpet, which is so confine an instrument, that nearly the fame passages must be used in all ages, so that time has robbed this song of but little of its novelty. Indeed, the divisions of this air have been revived of late years, and are now as fashionable, in frivolous and unmeaning melody, as ever.

There are many excellent songs in this volume; however, thefe and their peculiar beauties we must pass over, or our commentary will encroach too much on the limits of our biographical articles, as well as on the time and patience of those readers to whom the name and productions of our British Orpheus are alike unknown or indifferent. Yet we must observe, that there is a composition in Purcell's "Bonduca," in which he has anticipated a species of dramatic music, which has been thought of late invention; the words are "Hear ye gods of Britain!" which he has set in an accompanied recitative, "a tempo, or aria parlante. The beginning, however, with the base a pedale, has the true characteristic of recitative. Afterwards, when the base is put in motion, the whole has the properties of an air, ingeniously and spiritedly accompanied by two violins and a base. Besides the true dramatic call of this composition, there are new harmonies hazarded, which we do not recollect having seen in antient contrapuntalls, at least of our own country.

We dare proceed no further in analyzing the works of our illustrious countryman, though it would afford us great pleasure, as we never look at them without seeing a merit very superior to that of any of his contemporaries out of Italy, and even there, only the vocal compositions of Carissimi and Stradella seem to far pass them in grace and elegance. Carissimi appears to have been his model in his bell recitatives, and Lulli in the world; and it is manifest that he was fond of Stradella's manner of writing, though he never pillaged his passages.

We must not quit his vocal music without an honourable and grateful memorial of his catches, rounds, and glee, of which the humour, ingenuity, and melody, were so congenial with the national taste, as to render them almost the sole productions of the factious kind that were in general use for near fourscore years. And though the countenance and premiums bestowed of late years upon this species of composition, as well as modern refinements in melody and performance, have given birth to many glee's, of a more elegant, graceful, and exalted kind, than any which Purcell produced; yet he seems hardly ever to have been equalled in the wit, pleafantry, and contrivance of his catches.

Of fifteen anthems, with symphonies and instrumental parts, with innumerable odes and miscellanies, we have room to say nothing, though much praise is due to many of them.

An absurd custom prevailed in Purcell's time, which he carried to greater excess, perhaps, than any other composer, of repeating a word of one or two syllables an unlimited number of times, for the sake of the melody, and sometimes before the whole sentence has been heard. Such as no, no, no,—all, all, all,—pretty, pretty, pretty, &c. ad infinitum. But there is equal redundancy and obscurity in the use which the Italians make at present of i, ii, iii, and nò, nò, nò, in their songs.

Purcell
Purcell was so little acquainted with the unlimited power of the violin, that we have scarcely ever seen a becoming passage for that instrument in any one of his works; the symphonies and ritornels to his anthems and fongs being equally deficient in force, invention, and effect. And though his fonatas contain many ingenious, and, at the time they were composed, new traits of melody and modulation, if they are compared with the productions of his contemporary, Corelli, they will be called barbarous. But Corelli wrote for an instrument of which he was a great master: and who ever entirely succeeded in composing for one of which he was ignorant? When a great performer on keyed instruments condescends to compose for the violin, upon which he has never been a good player, or the voice, without knowing in what good singing conflicts, the passages all come from the head, and none from the hand, except the hand of a harpsichord player, which is ever unfit to suggest ideas either for a voice, or for any other instrument than his own. Such a composer for the violin must inevitably embarrass the player with perpetual awkwardness and difficulties without effect, which discover an utter ignorance of the finger-board.

If Purcell, by travelling, or by living longer at home, had heard the great instrumental performers, as well as great fingers, that arrived in this country soon after his decease, and had such to compose for, his productions would have been more regular, elegant, and graceful: and he would certainly have fet English words better than it was possible for any foreigner to do, for our feelings, however great his genius, or excellent, in other respects, his productions. But Purcell, like his successor, Arne, and others who have composed for the playhouse, had always an inferior band to the Italian opera composers, as well as inferior fingers, and an inferior audience to write for.

The diligent and candid Walther, by not having affigned to Purcell a niche in his Musical Dictionary, seems never to have heard of his existence; but Purcell was so truly a national composer, that his name was not likely to be whetted to the continent; and the narrow limits of his fame may be fairly ascribed, not only to the puerility and poverty of his compositions for instruments, for which the musical productions are an intelligible language to every country, but to his vocal compositions being solely adapted to English words, which render it unlikely for their influence to extend beyond the foil that produced them.

We should, however, have known as little of Lulli, as the French or Italians of Purcell, but for the partiality which Charles II. acquired, by his long residence on the continent, for the arts and amusements of France. The first attempts at operas here, after the Restoration, were either in French, or on the model of those that were then in high favour at Versailles. And whoever is equally acquainted with the recitative, we have almost said the general melody of Lulli and Purcell, must perceive a strong resemblance.

Purcell, however, having infinitely more fancy, and indeed, harmonic resources, than the Frenchified Tufan, his productions now afford far greater pleasure and amuseavour to a liberal lover of music, than can be found, not only in the productions of Cambert and Grubin, whom Charles II. and to flatter his majesty, Dryden, patronized in preference to Purcell, but in all the noisy monotony of the rhapsodist of Quantz.

Let those who shall think Purcell has sacrificed the national honour by conferring his reverence for the productions of Italy, compare the pecular productions of English musicians, from the death of Queen Elizabeth to the year 1683, with those of Carissimi, Cesti, Stradella, and innumerable others of great abilities, and if they do not equally hate music and truth, they will admire Purcell's probity, as well as his genius.

Indeed, music was manifestly on the decline, in England, during the seventeenth century, till it was revived and invigorated by Purcell, whose genius, though less cultivated and polished, was equal to that of the greatest masters on the continent. And though his dramatic style and recitative were formed in a great measure on French models, there is a latent power and force in his expression of English words, whatever be the subject, that will make an unprejudiced native of this island feel more than all the elegance, grace, and refinement of modern music less happily applied, can do. And this pleasure is communicated to us, not by the symmetry or rhythm of modern melody, but by his having forfitted, lengthened, and tuned, the true accents of our mother-tongue; those notes of passion, which an inhabitant of this island would breathe, in such situations as the words he has to set describe. And these indigenous expressions of passion Purcell had the power to enforce by the energy of modulation, which, on some occasions, was bold, affecting, and sublime.

The remarks are addressed to none but Englishmen: for the expression of words can be felt only by the natives of any country, who seldom extend their admiration of foreign vocal music, farther than to the general effect of its melody and harmony on the ear; nor has it any other advantage over instrumental, than that of being executed by the human voice, like faliggi. And if the Italians themselves did not come hither to give us the true expression of their songs, we should never discover it by study and practice.

It has been extremely unfortunate for our national taste and our national honour, that Orlando Gibbons, Pelham Humphrey, and Henry Purcell, our three best composers during the last century, were not blest with sufficient longevity for their genius to expand in all its branches, or to form a school, which would have enabled us to proceed in the cultivation of music without foreign assistance.

Orlando Gibbons died 1625, at forty-four.
Pelham Humphrey died 1674, at twenty-seven.
And Henry Purcell died 1695, at thirty-seven.

If these admirable composers had been blest with long life, we might have had a music of our own, at least as good as that of France or Germany; which, without the assistance of the Italians, has long been admired and preferred to all others by the natives at large, though their princes have usually foreigners in their service. As it is, we have no school for composition, no well-digested method of study, nor, indeed, models of our own. Instrumental music, therefore, has never gained much by our own abilities; for though some natives of England have had hands sufficient to execute the productions of the greatest masters on the continent, they have produced but little of their own that has been much esteemed. Handel's compositions for the organ and harpsichord, with those of Scarlatti and Alberti, were our chief practice and delight for more than fifty years; while those of Corelli, Geminiani, Albinoni, Vivaldi, Teifartini, Veracini, and Tartini, till the arrival of Giardini, supplied all our wants on the violin, during a still longer period. And as for the hautboys, Martini and Figler, with their scholars and imitators, all that we have listened to with pleasure.

If a parallel were to be drawn between Purcell and any popular composer of a different country, reasons might be assigned for supposing him superior to every great and favourite contemporary musician in Europe.

Carissimi and Stradella, if more polishec in their style, were certainly less varied, and knew still less of instruments, than
than our countryman. They had both, perhaps, more grace and regularity, but infinitely less passion and fire.

The elder Scarlatti was more riébérché and learned, but never so natural and effecting.

In Germany, if Keifer, during an active and much longer life, surpassed him in the number and excellence of his dramatic compositions, his productions for the church, could they be found, would, we believe, bear no comparison.

Lulli, blest likewise with superior longevity, composed also more operas than Purcell, and was the idol of the nation for which he laboured; but though his overtures long served as models, even to Purcell, as well as to the composes of all the rest of Europe, and his music was performed by better singers, and a more numerous band, supported by the patronage of a court, and all the splendour of ingenious and costly exhibition: it is easy to see that even his theatrical works are more manières, monotonous, and uninteresting in themselves, than those of Purcell; but in relinquishing the stage, and stepping on holy ground, we should have found, even in France, during all his glory, and the enthusiasm he raised, none of his votaries who would attempt to put his sacred music in comparison with that of our countryman.

Rameau, the successor of Lulli in court and popular favour, and who had more learning and theoretical knowledge in the art, than perhaps any practical musician of modern times; yet, in pathos and expression of words and the passions, he was Purcell's inferior, even upon the stage; and in the church, he had no claim to celebrity.

Handel, who flourished in a less barbarous age for his art, has been acknowledged his superior in many particulars; but in none more than the art and grandeur of his choruses, the harmony and texture of his organ fugues, as well as his great style of playing that instrument; the majesty of his hautbois and grand concertos, the ingenuity of the accompaniments to his songs and choruses, and even in the general melody of the airs themselves; yet in the accent, passion, and expression of English words, the vocal music of Purcell is, sometimes to our feelings, as superior to Handel's as an original poem to a translation.

PURCHASE. Samuel, was born at Thaxted, in Essex, in 1577. He was educated at Cambridge, and was presented to a vicarage in his native county. This cure he resigned to his brother, and came to live in London, for the purpose of conducting the great work he had undertaken. The first volume folio appeared in 1613, under the title of "Purcells Pilgrimage, or Relations of the World and the Religions Observed in All Ages and Places discovered from the Creation unto this Present." The other four volumes were published in 1625. To these the general title is "Haklytus Posthumus, or Purchas his Pilgrims: containing a History of the World in Sea-royages and Land-travels by Englishmen and others;" the name of Haklyt is introduced, because Purchas became possessed of the papers which he left behind him. This great work, of which the object is to connect ancient and modern history, was well received, but probably involved the author in debt. He had been collated to the rectory of St. Martin's Ludgate, and was chaplain to Abbot, archbishop of Canterbury. He died about the year 1628, at the age of fifty-one. Biog. Brit.

PURCHASE, in Law, in its largest and most extensive sense, is defined by Littleton to be the possession of lands and tenements, which a man hath by his own act or agreement, and not by descent from any of his ancestors or kindred. In this sense, it is contradistinguished from acquisition by right of blood, and includes every other method of coming to an estate, but merely that by inheritance; in which the title is vested in a person, not by his own act or agreement, but by the single operation of law. (Co. Litt. 18.) Purchase, in its vulgar and confined acceptation, is applied only to the acquisition of goods, lands, tenements, or the like, by means of money, or some other valuable consideration.

What we call purchas, perquisito, the feudists call conquisitu, conquetus, or conquisto, (see Conquest); both denoting any means of acquiring an estate out of the common course of inheritance; and this is still the proper phrase in the law of Scotland. The difference, in effect, between the acquisition of an estate by descent and by purchase, consists principally in these two points.

1. That by purchase the estate acquires a new inheritable quality, and is descible to the owner's blood in general, and not the blood only of some particular ancestor.

2. An estate taken by purchase will not make the heir answerable for the acts of the ancestor, as an estate by descent will.

According to this legal signification of the word perquisito, or purchase, it includes the five following methods of acquiring a title to estates, viz. écheat, occupancy, perquisition, forfeiture, and alienation, conveyance, or purchase, in its limited sense: under which latter head may be comprised any method in which estates are voluntarily resigned by one man, and accepted by another; whether that be effected by sale, gift, marriage-fettlement, devise, or other transmission of property, by the mutual consent of the parties. See the several articles, and Title.

Natural persons, incorporate persons, sole or aggregate, dead, dumb, and blind persons, minors, and all reasonable creatures, may purchase, except in some cases; but some have capacity to purchase, and not to hold, as aliens, felons, &c.; and others have ability to hold or not to hold upon a purchase, at the election of themselves or others, as infants, and feme covert's.

1 Inft, 2. 3. 11 Rep. 77. 7 Rep. 17.

PURCHASE and value of land. See Valuation of Land, and Political Economy.

PURCHASE of servit. See WRIT.

PURCHASE, in the Sea Language, has the fame signification with draw in, at land. Thus, they say, the caplenn purchas space, i.e. draws in the cable space; and when they cannot draw or halve any thing in with the tackle, they say, the tackle will not purchase.

PURCHASE is also a name given by sailors to any mechanical power employed in raising or removing heavy bodies, or in fixing or extending the ship's rigging. Such are the tackles, windlasses, caplenns, fcrews, and handspikes.

PURCHASE-Book, among Traders, is the name given to a book, which is a kind of journal, containing an account of all the purchases made, or things bought in the day.

PURCHASER, First, Perquisitor, in Law, denotes the person who first acquired an estate to his family, whether the same was transferred to him by sale or by gift, or by any other method, except only that of descent. See Descent.

PURCHASING of Estates, in Agriculture, the business of buying landed property. In order to perform this sort of bargain with propriety, and to the best advantage, attention is necessary to be had to a great variety of circumstances of different kinds, which respect the nature, quality, situation, condition, value, and conveniences of the property. See Valuation of Land.

But it is probably best done, when to any extent, by a surveyor or other person who is perfectly conversant with the nature of the busines, and fully acquainted with the real
real value of landed property in the district where the purchase may be situated or met with.

It has been observed by Mr. Marshall, that there are two methods of making bargains of this kind, the one by public biddings, the other by private treaty or contract: in either of which, a certain degree of caution is common prudence. In the former, however, the conditions being fixed, an accurate valuation is the best safeguard; and, in the latter, among honnête men little more is required.

In purchasing by private contract, the particulars which may be previously required to be furnished by the seller, are the quantities of the several pieces of the lands which are on sale, together with the maps, or rough drafts, of the same; the tenure under which they are held; some assurance as to the title of the seller; and his right of alienation; the tenure under which the several farms are let; and, if on lives, the ages of the nominees; if for a term of years, the number which are unexpired; if at will, the notices with which the tenants have been served, if any have been given.

An abstract of the covenants under which they are let; particularly of those which relate to taxes and repairs, to the expenditure of produce, to the ploughing of grasslands, &c. &c.

The existing rents and profits receivable; whether for tenanted lands, appurtenances, or abstract rights; with the estimated value of the demesne, and the woodlands in hand; together with the estimated value of the timber growing upon the estate on sale; as well as of the minerals and foils on which it may contain.

The outgoings to which the estate is liable; the proposed time of the delivery of possession; the price and the mode of payment which are expected.

And next, it will be proper to lay down the particulars of the instructions to be given to a surveyor, or other valuer, of the estate to be purchased. It will be right, however, to premise, that much, in this respect, depends on the probability of purchasing; and on the time which is allowed for making the estimate. In cases of sale by public auction, when there can be no certainty as to purchase, and where the time for valuation is limited, a rough estimate of each farm, and a general idea of the value of the timber and other appurtenances, may be all that can be prudently ascertained. But in a sale by private contract, where the refusal of an estate is granted, and time allowed for deliberate inquiry, a more minute investigation may be proper; especially where there is every reason to believe that a bargain will take place. For the fame report will not only serve as a guide to the purchaser, but will become a valuable foundation, on which to ground the future management of the estate. And for these and other reasons, a purchase by private contract is most to be desired by one who is not in the habit of personally attending public sales, and is unacquainted with the usages of an auction room.

It may be noticed, that the particulars to be required from a surveyor, or surveyors, in these cases, are principally these: the rental value of each field or parcel of land, with the flate in which it lies, as to arable, meadow, pasture, or woodland: the value of the timber and other appurtenances: the character: the state and flate of management of each farm or tenement, with the eligibility of the occupier; together with the state of repair of buildings, gates, fences, water-courses, and roads, the amount of the encumbrances and outgoings. And, lastly, the probable value of the improvements of which the estate may appear to be capable: whether by the several means that are commonly practiced, or by new regulations and improved modes of agricultural management, that may admit of being introduced.

It is added, that these several particulars of information being procured, the subjects of treaty are few. The two statements having being duly compared, so that no misunderstanding can take place between the parties, the price, and the times and mode of payment, are the principal matters of agreement. A clear understanding respecting the custody of title deeds and the expenses of conveyance, require, however, to be enumerated among the preliminaries of purchase.

In these transactions, it is also supposed, the business of negotiation is best carried on by letters; which become vouchers of facts. Whatever is done by interview, requires to be reduced to writing, and to be read by or to the parties before they separate, that no possibility of misconception may arise. And, added to these precautions, it is proper in large purchases, and when abstracts of intricate title deeds are to be made out, and examined, that a legal contract or memorandum of agreement should be entered into, for the mutual satisfaction and hurry of the parties. This contract and the deed of conveyance, which is the instrument which is legally to transfer the property from the seller to the purchaser, may be read to conclude and ratify the business of purchase. And in this part of it, legal assurance is essentially necessary; to examine existing deeds, and see that the seller has a legal right and clear title to the land, and a legal power to dispose of it; as well as to draw up or examine the fresh deed of conveyance, and see that it is sufficient to transfer the property legally and adequately to the purchaser.

PURCHASEN, in Geography, a town of Spain, in the province of Grenada; 60 miles E. of Grenada. N. lat. 37° 19'. W. long. 2° 30'.

PURE, something free from any admixture of foreign or heterogenous materials.

PURE FIRE. See FIRE.

PURE HYPERBOLA, in Conics, is a hyperbola without any oval, node, ipike, or conjugate point. See CURVE.

PURE MATHEMATICS. See MATHEMATICS.

PURE PROPORTION. See PROPORTION.

PURE QUADRATIC. See QUADRATIC.

PURE RESIGNATION. See RESIGNATION.

PURE VILLAGE. See VILLAGE.

PURE A., or PUNA, in Geography, a town of Chili; 80 miles S.S.E. of La Conception.

PUREEWAR, a town of Hindooftan, in Oude; 10 miles N. of Baharath.

PURIG, formerly Pura, once the capital of Gedrofia (Mekran), and termination of the toilsome march of Alexander towards the frontiers of Caramania, is now a mean village.

PURRENDRA, in Mythology, a name of Indra, the Hindoo regent of the firmament. (See INDRA.) The word is said to mean defender of towns, the Indian Jupiter having, in revenge for sacrificial flights or negligences, frequently, according to the Hindoo books, assumed that character. The ancient city of Ouein, the capital of Malwa, was, according to tradition, destroyed by Indra. See OUEIN.

PURESIL, in Geography, a town of Hindooftan, in the circuit of Ciccacle; 40 miles N.W. of Vizianagram.

PURETTA, a name given by some writers to the common shining black quand, used to flour over writing, and erroneously called by some feel-dark.

It is a natural mineral substance, found on the shores near Genoa, and in other places.

PURPLED.
PUR

PURPLED, ornamental work, whether in stone or other materials, representing embroidery or lace work.

PURPLEW, a term in Heraldry, expressing ermine, peans, or any of the fur, when they compose a border found a coat of arms.

Thus they say, he beareth gules a border, purlew, vary; meaning, that the border is vary.

PURG, or FORS, in Geography, a town of Persia, in the province of Laristan; 60 miles N. E. of Lar. Lat. 28° 30'. E. long. 54° 40'.

PURGATION, Purgatio, the act of purging, scouring, or purifying any thing, by separating and carrying off any impurities found therein.

Purgation, in Pharmacy, is the cleansing of a medicine by retrenching its superfluities; as taking the wood and seeds out of caffia, and the stones out of dates, tamarinds, and other fruits.

Purgation is also used, in Chemistry, for several preparations of metals and minerals, intended to clear them of their impurities; more usually called purification and refinement.

The ordinary purgation of mercury is performed, by passing it through a chamois skin. (See MERCURY.) Gold is purged by the coppel, cementation, &c. See Gold, Copper, &c.

Purgation, in other metals, is performed by repeated fusion, &c.

Purgation, Catharistica, in Medicine, the evacuation of the alimentary canal of its fecal contents, by means of substances which stimulate its fibres, and excite them to a more active peristaltic motion. Purgation is also sometimes carried farther, and, by causing a copious discharge of fluids from the exhalent vels of the inner surface of the bowels, produces a considerable evacuation from the system at large. For an elucidation of the doctrine of purgation, see CATHERISTIC.

Purgation, in Law, is the clearing one's self of a crime, whereof publicly suspected or accused before a judge, called also judicium Deus.

Of these purgations there was anciently much use in England, especially touching matters of felony charged on clerks; and there is something of them still retained in the ecclesiastical court on suspicion of incontinency, &c. Purgation is either canonical or vulgar.

Purgation, Canonical, is that preferred in the canon law, the form of which, obtaining in the spiritual court, is, that the party suspected shall take his oath that he is clear of the fact objected against him; and bring so many of his honest neighbours, not above twelve, as the court shall affign him, to swear, on their confidences, that they believe he swears truly.

The canonical doctrine of purgation, whereby the parties were obliged to answer upon oath to any matter, however criminal, that might be objected against them, continued till the middle of the 17th century to be upheld by the spiritual courts; when the legislature was obliged to interpose, to teach them a lesson of similar moderation. By the statute of 13 Car. II. cap. 12. it is enacted, that it shall not be lawful for any bishop, or ecclesiastical judge, to tender or administer to any person whatsoever, the oath usually called the oath ex officio, or any other oath whereby he may be compelled to confess, accuse, or purge himself of any criminal matter or thing, whereby he may be liable to any censure or punishment. But this doth not extend to oaths in a civil suit; and, therefore, it is still the practice both in the spiritual courts, and in equity, to demand the personal answer of the party himself upon oath. Yet if in the bill any question be put, that tends to the discovery of any crime, the defendant may thereupon demur, and refuse to answer. Anciently, upon the allowance of the benefit of clergy, the person accused was delivered to the ordinary, to make his purgation, which was to be before a jury of twelve clerks, by his own oath affirming his innocence, and the oaths of twelve compurgators as to their belief of it. But now, by the flat. 18 Eliz. cap. 7. this kind of purgation is also taken away; and the person admitted to his clergy shall not be delivered to the ordinary.

Purgation, Vulgar, being the most ancient manner, was by fire, or water, or combat; used by infidels, and by Christians too, till abolished by the canon law. See ORDEAL, and Cornell.

Combat, though now diffused, may yet be still practised by the laws of the realm, in cases where evidence is wanting, and where the defendant rather chooses combat than any other trial. See Combat.

Terris beatis, &c. redabendis poti Purgationem. See Terris.

Purgation, in Rhetoric, is used for that kind of defence which takes place when the accused person owns the fact, but denies that he did it with design, or with any bad intention.

Purgation, in Tragedy, is a term which Aristotle uses for the effect of tragedy on the mind.

That philosopher observes, that tragedy, by means of the terror and compulsion which it excites, purges passions out of the soul.

Indeed, Corneille adds, that tragedy frequently creates passions, instead of purging them; so that he takes Aristotle's purgation to be no more than a chimera.

Purgations, Monfradus, the catamenia or menes of women.

Purgative, or Purgino-Medica, a medicament, which evacuates the contents of the bowels by a flux. See Cathartic.

Purgatory, Purgatorium, in the Romish church, a place where the just are supposed to suffer the pains due to their sins, for which they have not satisfied in this world.

It is by the mercy of God, the indulgences of the church, and the prayers of the faithful, that people are supposed to be delivered out of purgatory.

This doctrine of purgatory, which some derive from the Platonic fancies of Origen, the Montanist of Tertullian, pretended visions, and pagan stories, rhetorical flourishes, and doubtful expressions of the later fathers, and in which we may discern an obvious resemblance to the famous pagan doctrine, concerning the purification of departed souls by means of a certain kind of fire, was partly introduced, at least in the spirit of it, towards the close of the fifth century, and by Gregory the Great in the sixth century; but it was not, however, positively affirmed till about the year 1140, nor made an article of faith till the council of Trent. Sess. 25. Decret. de Purgat. See PAPISTS and POPERY.

In Ireland is a place called "St. Patrick's purgatory," where, as the legend has it, at the prayers of St. Patrick, bishop of the place, there was made a visible representation of the pains which the wicked undergo after death, in order to deter sinners, &c.

Purgatty, in Geography, a town of Hindoostan, in the circar of Cicacole; 40 miles N.W. of Viznagaram.

Purge, in Medicine, a term frequently used for a dose of some purgative medicine.

Purging Alk., Butler's. See Alk.

Purging Grain, Gily, in Botany. See Sesamum.

Purging Nut, in Botany. See Jatrophia.

Purging Thorn. See Buckthorn.

PURGLITZ,
PURGLITZ, or Krzimowka, in Geography, a citadel of Bohemia, in the circle of Rakonitz, where the royal treasures were anciently kept, and late prisoners confined five miles S.E. of Rakonitz.

PURGOT, a town of Hindooftan, in Coimbetore: 35 miles W. of Ardenelle.

PURGOW, a town of Hindooftan, in Bagdana: 25 miles E.N.E. of Balken.

PURGSTALL, a town of Austria; four miles N. of Scheibs.

PURIFICATION, in Chemistry, &c. the act of purifying or refining natural bodies; or of separating the faces and impurities from them.

For the methods of purifying metals, gold, silver, iron, copper, tin, &c. see GOLD, SILVER, &c. and REFINING.

For the purification of semi-metals, minerals, and other matters, as antimony, sulphur, camphor, faltpetre, &c. see ANTIMONY, SULPHUR, CAMPHOR, &c.

PURIFICATION, in Pharmacy. See TRYING.

PURIFICATION, in Matters of Religion, denotes an offering made the priest by women rilling out of child-bed, before they are re-admitted into the church.

By the law of Moses, a woman, after bringing forth a male child, was unclean forty days: after a female, eighty days: during which time, she was not to touch any thing holy, nor to go near the temple, but was to continue without doors, separate from all company, and commerce of others.

This term expired, she was to present herself at the temple, and at the door of the tabernacle, to offer a lamb, as an holocaust, and a pigeon or turtle; which the priest taking, offered to God, and prayed for her, that she might be purified.

This ceremony, which consisted of two things, an holocaust, and a sacrifice of expiation, was called פַּנְיָה פָּנָי, purification, purgatio.

The holy Virgin, though, according to the fathers, exempt from the terms of the law, yet complied with it, and, at the time prescribed, went to the temple, and accomplished the law; in commemoration of which the church yearly solemnizes the feast of the Purification of the Virgin, on the second of February; called also the Feast of Candlesmas.

Purification, The Feast of the, seems to be very ancient. It is ordinarily said to have been instituted in the time of Julijtinian, in the year 542, and on this occasion of a mortality, which that year dispeopled almost the whole city of Constantinople. Yet there are some, who imagine it to have been observed before, though in another manner; and on a different day from that fixed by Julijtinian; vide between the Circumcision and Epiphany. See CANDLEMAS.

The same day is the presentation of our Saviour in the temple.

Purification, in Geography, a town of Mexico, in the province of Xalchitl; eight miles S. of Compostella Nuova. N. lat. 19° 58'. W. long. 105° 46'.

PURIM, a solemn feast held among the Jews on the fourteenth and fifteenth of March, in memory of their deliverance from the conspiracy of Haman by Esther. See ESTHER.

This feast, which derives its name from the Persian word purim, q. d. lots, because it was by the casting of lots that Haman determined this time for the destruction of the Jews, is the Baccalaureate of these people, which they celebrate with all manner of rejoicing, mirth, and jollity; indulging themselves with every kind of luxury, especially in drinking wine even to drunkeness, which they consider as part of the duty of the festival; because it was by means of the wine banquet (they say) that Esther made the king's heart merry, and brought him into that good humour, which inclined him to grant the request presented by her for their deliverance; and, therefore, they think they ought also to make their hearts merry, when they celebrate the commemoration of it. During this festival the book of Esther is solemnly read in all their synagogues from the beginning to the end, at which they are all to be present, men, women, children, and strangers, because all shared in the benefit of the deliverance which Esther obtained for them. And as often as the name of Haman occurs in the reading of this book, the custom is for all to clap with their hands, and stamp with their feet, and cry out, Let his memory perish. Prideaux's Conn. vol. ii. p. 456.

PURITANS, in Ecclesiastical History. See CATHARI

and NOVATIANS.

PURITANS is also a term anciently used for the Calvinists of Great Britain, from their professing to follow the pure word of God, in opposition to all traditions, human confitu-

tions, and other authorities.

The separation, whence this distinguishing appellation took its rise, commenced on the following occasion. Upon the accession of queen Mary, it is well known that popery revived in this kingdom; the flagons of king Edward were re-erected, and the penal laws against heretics were put in execution against the reformers. Many suffered at home; and others escaped the fury of persecution by seeking refuge in foreign countries. Some went into France and Flanders; some to Geneva; and others into those parts of Germany and Switzerland, where the reformation had taken place, and where the magistrates received them with great humanity, and allowed them places for public worship. The exiles were most numerous at Frankfort; and there that contest and divition began, which gave rise to the Puritans, and to that separation from the church of England, which continues to this day.

In the year 1554, some of the English fugitives settled in this city; and agreed to conduct their worship, without answerring aloud after the minister, and without using the liturgy and furnishes; to begin the public service with a general confession of sins, then to sing a psalm, after which the minister prayed for the divine affiance, and next proceeded to the sermon; after sermon, a general prayer for all estates, and particularly for England, at the end of which was subjoined the Lord's prayer, and a rehearal of the articles of belief; then the people were to sing another psalm, and the minister to dissimilate them with a blessing. Such was the order which they had unanimously adopted; and having chosen a minister and deacons, they invited their dispersed brethren to join with them. In the year 1556, Dr. Cox, afterwards bishop of Ely, came to settle at Frankfort with several of his friends; who interrupting the public service by answering aloud after the minister, and reading the whole liturgy, in violation of the agreement upon which the congregation was formed, overpowered the first settlers; and obtaining leave of the magistrates for the free use of king Edward's service-book, performed divine worship according to the rites that had been authorized by that prince; while others, who preferred the Genevan method of worship, as more pure and simple, left the city of Frankfort, and removed to Basle and Geneva. Thus commenced the distinction of Puritans and Conformists, by which the two parties were afterwards known. The former were called Conformists, on account of their compliance with the ecclesiastical laws enacted by Edw. VI. and the denominations of Nonconformists and Puritans were given to the latter, from their initiating upon a form of worship, more exempt from superstition, and of a purer kind than
than the liturgy of Edward seemed to them to be. Upon
the accession of queen Elizabeth, the exiles returned to
England, where each party strove to advance the reformation
according to their own standard. The queen, with those
who had weathered the storm at home, were only for
refounding king Edward’s liturgy; but the majority of the
exiles were for the worship and discipline of the foreign
curches, and refused to comply with the old establishment,
declaming loudly against the popish habits and ceremonies.
However, the queen’s party prevailed; and in 1559 a com-
mittee of divines was appointed to review king Edward’s
liturgy, who were instructed to strike out all offensive
passages against the pope, and to make people easy about
the belief of the corporal presence of Christ in the sacra-
ment. But no alterations were made in favour of those who
now began to be called Puritans, from their attempting a
purer form of worship and discipline than had yet been
established; and while sentiments in many points were
agreeable to those maintained by John Wickliffe, the first
reformer. For they agreed with him in opinion, that in the
sacrament of orders there ought to be but two degrees,
prebendaries and bishops, and deacons; that all human tra-
ditions are superfluous and hurtful; that we must practice
and teach only the laws of Christ; that mystical and sig-
nificant ceremonies in religious worship are unlawful, and
that to refrain men to a prescribed form of prayer is con-
trary to the liberty granted them by God. The old festivas,
with their eyes and the popish habits, were continued as they
were in the second year of king Edward VI. In 1558 the
act of supremacy was passed, in which there is a remarkable
clause, that gave rite to the court of high-commission,
which proved afterwards so offensive; and in 1559 was
passed an act for the uniformity of common prayer, and
service in the church, and administration of the sacraments.
The Puritans remonstrated against these proceedings, and
complained, that the gross superfluities of popery, which
they had looked upon as abrogated and abolished, were
now revived, and even imposed by authority. Some re-
quired nothing less than that the church of England should
be exactly modelled after that of Geneva; others only de-
sired liberty of conscience, with the privilege of celebrating
divine worship in their own way; but neither party ob-
tained the object of their wishes. The queen, intent upon
the suppression of this troublesome sect (as she was used to
call it), permitted its enemies to employ for that purpose all
the resources of artifice, and all the severity of the laws.
The court reformers pleaded, that every prince had authority
to correct all abuses of doctrine and worship within his own
territories; the Puritans, on the other hand, whilst they
disowned all foreign authority and jurisdiction over the
church, could not admit of that extensive power which the
crown claimed by the supremacy; apprehending it un-
reasonable, that the religion of a whole nation should be at
the disposal of a single lay person. However, they took the
oath, with the queen’s explication in her injunctions, as
retaining her majesty only to the ancient and natural rights
of sovereign princes over their subjects.

Farther, the court reformers allowed, that the church of
Rome was a true church, though corrupt in some points of
doctrine and government; that all her ministrations were
valid, and that the pope was a true bishop of Rome, though
not of the universal church. But the Puritans affirmed
the pope to be antichrist, the church of Rome to be no true
church, and all her ministrations to be superfluous and idol-
ratous; they renounced her communion, and durst not
suspends the validity of their ordinations upon an unint-
rupted line of secession from the apostles through her hands.

Moreover, it was agreed by all, that the holy scriptures
were a perfect rule of faith; but the bishops and court re-
formers did not allow them to be the standard of discipline
or church government; affirming that our Saviour and his
apostles left it to the discretion of the civil magistrate, in
those places where Christianity should obtain, to accommo-
date the government of the church to the policy of the state.
But the Puritans apprehended the holy scriptures to be a
standard of church discipline as well as of doctrine; at least
that nothing should be imposed as necessary but what was
expressly contained in, or derived from them by necessary
consequence, and, besides, they maintained that the dis-
cretionary power was not lodged with the civil magistrate,
but with the spiritual officers of the church. Farther, the
court reformers maintained, that the practice of the primitive
church for the first four or five centuries was a proper
standard of church government and discipline, and in some
respect s a better than that of the apostles, which (according
to them) was only accommodated to the infant state of the
church while it was under persecution, whereas theirs was
founded on the grandeur of a national establishment. Whereas
the Puritans were for adhering to the bible in the main prin-
ciples of church government, and for admitting no church
officers or ordinations, but such as are herein mentioned;
and they apprehended, that the apostles, in establishing the
first Christian church on the arithmetical plan they observed in the Jewish sanhedrin, designed it as an unchangeable
model to be followed in all times and places. These court
reformers also maintained, that things indifferent in their
own nature, which are neither forbidden nor commanded in
the holy scriptures, such as rites, ceremonies, habits, &c.
might be settled, determined, and made necessary by the
command of the civil magistrate, and that in such cases it
was the indispensible duty of all subjects to obey them.

But the Puritans insisted, that those things which Christ had
left indifferent, ought not to be made necessary by any
human laws, and that such rites and ceremonies as had been
abused to idolatry, and had a manifest tendency to lead men
back to popery and supercretion, were no longer indifferent,
but to be rejected as unlawful. Nevertheless, both parties
agreed too well in affording the necessity of a uniformity of
public worship, and of calling in the sword of the magis-
trate for the support and defence of their several prin-
ciples; which they made all use of in their turns, as they
could grasp the power into their hands. The standard of
uniformity, according to the bishops, was the queen’s
supremacy, and the law of the land; according to the
Puritans, the decrees of provincial and national synods,
allowed and enforced by the civil magistrate; but neither
party was for admitting that liberty of conscience, and free-
dom of profession, which is every man’s right, as far as is
confident with the peace of the government under which he
lives.

In the year 1564, upon a report that the habits, enjoined
on the clergy, were generally neglected, and also of inten-
tion to other imposed forms, the queen directed the
ecclesiastical commissioners to consult some proper methods
to reduce them to an exact uniformity; upon which they
agreed on certain advertizements (as they were called), partly
for due order in preaching and administering the sacraments,
and partly for the apparel of ecclesiastical persons. To
these advertizements certain protestations were annexed,
to be made, promised, and subscribed by such as should here-
after be admitted to any office or cure in the church. The
queen, though she would give no authority to the adverti-
iments, which had occasioned much remonstrance and com-
plaint, sufficed out a declaration in 1564, peremptorily re-
quiring
Puritan uniformity in the habits, upon pain of prohibition from preaching, and deprivation. Parker, the archbishop of Canterbury, was violent and unrelenting; and by various methods of severity, harassed, silenced, and deprived many of those who ventured the use of the habits. The infamed ministers, finding that renewed applications to the queen and her commissioners were ineffectual, published, in 1566, a small treatise in vindication of their conduct; in which they allege, that neither the prophets of the Old Testament, nor the apostles of the New, were distinguished by their garments; that a confusion of garments in the Christian church did not generally obtain till long after the rising of antichrist; that the garments against which they objected, had been abuses to idolatry, forcery, and all kinds of conjurations; that they were an offence to weak Christians, an encouragement to ignorant and obfolute papists, and the use of them an affeotation of returning to their communion: that at bell they were only human appointments, fulfilling to the apostles reproach, Col. ii. 20—22; that allowing them to be indifferent (which they did not grant), yet they ought not to be imposed, because it was an infringement of the liberty with which Christ had made them free; and finally they urged the suffrage of foreign divines, who all condemned the habits, though they were not willing to hazard the reformation in its infancy, on account of them.

If, at this time, the habits and a few ceremonies had been left indifferent, both ministers and people would have acquiesced; but it was the compelling of these things by law that made them separate from the established church. Accordingly, in 1566, they came to a resolution, alleging it to be their duty, in their present circumstances, to break off from the public churches, and to assemble, as they had opportunity, in private houses, or elsewhere, to worship God in a manner that might not offend against the light of their confessions; and it was debated among them, whether they should use as much of the common prayer and service of the church as was not offenive, or resolve at once, since they were cut off from the church of England, to set up the pure and simple form of worship, most consonant to the holy scriptures, and to the practice of the foreign reformers. The latter of these measures was concluded upon; and accordingly they laid aside the English liturgy, and made use of the Geneva service-book. However, it was necessary to obviate, that though all the Puritans of these times would have remained in the church, if they might have been indulged in the habits, and that the remnant, after they were imposed from being satisfied with the hierarchy, there were other objections besides those for which they were deprived; of which we shall here subjoin a summary. They complained of the bishops alloting to be thought a superior order to prebendaries, and claiming the sole right of ordination, and the use of the keys; and assuming, in connection with their offices, temporal dignities, titles, and employments. As long, however, as the English bishops pretended to derive their dignity and authority from no other source than the laws of their country, and pleaded a right, merely human, to the rank they held in the church and state, the controversy was carried on without excessive animosity and zeal; but the flame broke out with redoubled fury in the year 1588, when Bancroft, afterwards archbishop of Canterbury, ventured to assert that the order of bishops was superior to the body of prebendaries, not in consequence of any human institution, but divina, or by the express appointment of God himself. Further, the Puritans excepted against the titles and offices of archdeacons, deans, chapters, and other officials, belonging to cathedrals, as having no foundation in scripture, or primitive antiquity, and intruding upon the privileges of the prebendaries in the several dioceses. They complained of the exorbitant power and jurisdiction of the bishops and their chancellors in their spiritual courts, as derived from the canon law of the pope, and not from the word of God, or the statute law of the land. They lamented the want of a godly discipline, and were uneasy at the pronomicious and gemonal access of all persons to the Lord's table. Though they did not dispute the lawfulness of certain forms of prayer, provided a due liberty was allowed for prayers of their own composition before and after sermon, yet they disliked the frequent repetition of the Lord's prayer in the liturgy, the interruption of the prayers by the frequent repetitions of the people, some passages in the office of marriage, as With my body I thee worship, and in that of burial, as In fare and certain hope of the resurrection to eternal life, pronounced over the world of men, if not excommunicated, &c. They also objected against the reading of the apocryphal books in the church, while some parts of canonical scripture were omitted; and though they did not dislike the hirmaries, they thought that no man should be ordained a minister in the church who was not capable of preaching and expounding the holy scriptures. They disapproved of several of the church festivals or holidays, as having no foundation in scripture, or primitive antiquity; and they disallowed of the cathedral mode of worship: nor did they approve of musical instruments in the church service. Finally, they feruped conformity to certain rites and ceremonies, which were enjoined by the rubric, or the queen's injunctions; as the sign of the cross in baptism, baptism by midwives, or other women, in cases of sickness, and the mode of churching women; the use of god-fathers and god-mothers, to the exclusion of parents from being sureties for the education of their own children; the cedulm of confirming children, as soon as they could repeat the Lord's prayer and their catechism, by which they had a right to come to the sacrament, without any other qualification, and the imposition of hands, as a sign of the divine favour, which seemed to them to imply a sacramental efficacy in this ceremony; kneeling at the sacrament of the Lord's supper, whilst they considered that Christ gave it to his disciples rather in a poulch of sealing than of adoration; that it had no foundation in antiquity; that it had been grossly abused by the papists to idolatry in their adoration of the host; and that, if the poulch were indifferent, it ought not to be imposed as a necessary term of communion; nor did they approve of administering either of the sacraments in private houses, even in cases of danger; bowing at the name of Jesus, giving the ring in marriage, which they considered, as derived from the papists, who made marriage a sacrament, and the sign a sort of sacred sign or symbol; the prohibition of marriage during certain times of the year, and the licensing it for money: and, lastly, the wearing of the surplice, and other vestments to be used in divine service.

In points of doctrine there was, at this time, no difference between the Puritans and Conformists; and if we add one article more to the preceding, we shall have the principal heads of controversy between the church of England and the Protestant Dissenters, at this day: viz. the natural right which every man has to judge for himself, and make profession of that religion he apprehends most agreeable to truth, as far as it does not affect the peace and safety of the government under which he lives; without being determined by the prejudices of education, the laws of the civil magistrate, or the decrees of councils, churches, or synods. See Protestant Dissenters.

Towards the latter end of Queen Elizabeth's reign, there arose a party, which were first called Rotten, and then for overthrowing,
overthrowing, the received opinions concerning predestination, perseverance, free-will, effectual grace, and the extent of Christ's redemption. The clergy of the episcopal church began to lean towards the notions concerning these intricate points, which Arminius propagated some time after this; while on the other hand, the Puritans adhered rigorously to the system of Calvin. Several episcopal doctors remained attached to the same system in the reign of James I. &c. and all these abettors of Calvinism, whether episcopal or presbyterian, were called doctrinal Puritans. At length, according to Mr. Fuller, (Church Hist. book ix. p. 97; book x. p. 100.) the name was extended to rigmatize all those who endeavoured in their devotions to accompany the minifter with a pure heart, and who were remarkably holy in their conversation; so that a Puritan was a man of severe morals, a Calvinist in doctrine, and a Non-conformist in the ceremonies and discipline of the church, though he did not totally separate from it.

Queen Elizabeth was violent in her opposition to the Puritans through the whole course of her reign; and besides the ordinary courts of the bishops, she erected, as we have already observed, a new tribunal, called the court of high-commission, which suspended and deprived men of their livings, not by the verdict of twelve men upon oath, but by the solemn determination of three commissioners of her own nomination, founded upon not the statute law of the realm, but upon the canon law; and instead of producing witnesses in open court to prove the charge, they assumed a power of administering an oath ex officio, by which the prisoner was obliged to answer all questions the court should put to him, though never so prejudicial to his own defence. If he refused to swear, he was imprisoned for contempt; and if he took the oath, he was convicted upon his own confession.

During the reign of James I. from whom the Puritans expected more indulgent treatment, they were treated with great severity, and many of them were obliged to leave the kingdom, and retire to Holland; and from thence considerable numbers migrated to America in the year 1620. All were Puritans, in the estimation of King James, who adhered to the laws of the land in opposition to his arbitrary government, though otherwise ever so good churchmen. These were called Puritans in the flate; and those who scrupled the ceremonies, and adhered to the doctrines of Calvin, were Church Puritans, who, though comparatively few, yet being joined by those of the other class, became the majority of the nation. The success which attended the first emigrants, who settled in that part of America afterwards called New Plymouth, engaged great numbers of Puritans, who groaned under the oppression of the bishops, and the severity of a court, by which this oppression was authorized, to follow the fortunes of these religious adventurers; and this produced a second emigration in the year 1629, which gave birth to the second grand colony, commonly known by the name of the Massachusetts's Bay. The colony of Connecticut was formed by emigrants of the same class in 1636, and that of New Haven in 1637, who fled from the persecution of Laud, and the oppressions of the star-chamber and high-commission courts. Afterwards, when the Puritans were not allowed to transport themselves to New England, many of them removed, with their families, into the Low Countries.

After the reformation of Charles II. in the year 1662, the name of Puritans, says bishop Burnet, was changed into that of Protestant Non-conformists, who were subdivided into Presbyterians, Independents, Anabaptists, and Quakers. At this time a public law, called the Act of Uniformity, was enacted, by which all who refused to observe the rites, and subscribe the doctrines of the church of England, were entirely excluded from its communion. From this period until the reign of king William III. the Non-conformists were in a precarious and changing situation, sometimes involved in calamity and trouble, and at other times enjoying some intervals of tranquillity and certain gleams of hope, according to the varying spirit of the court and ministry, but never entirely free from perplexities and fears. But in the year 1689, their affairs took a favourable turn, when a bill for the toleration of all Protestant Dissenters from the church of England, except the Socinians, passed in parliament, almost without opposition, and delivered those who could comply with the conditions it imposed, from the penal laws to which they had been subjected by the act of uniformity, and other acts passed under the house of Stuart. For the present state of the toleration, see TOLERATION. See also CORPUS. ACT and TEST. Neal's Hist. of the Puritans, in 4 vols. 8vo, pa6im.

**PURITY, in Oratory, is one of the constituent parts of elegance, and denotes the choice of such words and phrases as are suited and agreeable to the use of the language in which we speak. Grammarians reduce the faults which they oppose to it two sorts, which they call barbarism and solecism; the former of which respects single words, and is an offence against etymology, and the reproach of it is incurred by the use of words entirely obsolete, or by the use of words entirely new, or by new formations and combinations, from simple and primitive words in present use. The latter respects the construction of words, and is an offence against syntax: to which Dr. Campbell adds a third class of faults, under the denomination of impurity, which is an offence against lexicography, the business of which is to assign to every word of the language the precise meaning or meanings which use hath aligned to it. This impurity occurs both in single words and in phrases. Dr. Ward recounts the principal things that vitiate the purity of language. It often happens, he says, that such words and forms of speaking, as were introduced by the learned, are afterwards dropped by them, as mean and fordid, from a seeming bafeness contracted by vulgar use; and it is common to language, with all other human productions, that it is in its own nature liable to a constant change. (Hor. Art. Poot. v. 68.) We must, therefore, no less abstain from antiquated, or obsolete words and phrases, than from fordid ones. On the other hand, we should refrain from new ones, and such, whose use has not been yet sufficiently established, at least among those of the belles lettres. Besides, any mistake in the sense of words or their construction, is opposed to purity: for to speak purely is to speak correctly. And farther, a distinction ought to be made between a poetic diction, and that of prose writers: for poets in all languages have a sort of peculiar dialect, and take greater liberties, not only in their figures, but also in their choice and disposition of words: so that what is a beauty in them, would often appear unnatural and affected in prose. Ward's Or. vol. i. p. 368 &c. Campbell's Phil. of Rhet. vol. i. p. 409. &c.

**PURKAI, in Geography, a town of Hindooftan, in Bahar; 33 miles N. of Ramgar.

**PURLEU. See PULFE.

**PURLEU-Woods, such as formerly constituted parts of the royal forests, but of which the owners have obtained grants from the crown, and permission to disport them, and which not being now subject to any of the laws or regulations by which different interests in forest woods are conducted, may, Mr. Donaldson says, be to all intents and purposes considered as private property. And, he adds, that
that the manner in which these woodlands are occupied is
exactly the same as that of many of the royal forests, with
the exception of the right of palurage, and for that reason
much more productive and beneficial. See Woods and
Royal Forests.

Purlieu, or Purlieu, or Pouralle, formed from the
French pur, pure, and lieu, place, is all that ground near any
forest, which, being added to the ancient forest by our kings,
was, by perambulation, granted by some of their successors,
fevered again from the same, and made purlieu, i.e. pure
and free from the laws and obedience of the forest.

A purlieu, or pouralle, is defined a circuit of ground ad-
joining to the forest, and circumscribed with inviolable
boundaries, known only by matter of record; which com-
pacts of ground was once forest, and afterwards was dis-
afforested by the perambulations made for severing the new
forest from the old.

Purlieu, or pouralle, commenced after the manner fol-
lowing. King Henry I. at his accession to the crown in
1154, took so much delight in the woods of this kingdom,
that, not being contented with those he found there, though
many and large, he began to enlarge divers of them, and to
disafforestrate the lands of his subjects newly adjoining to the same.

His successors, Henry II. and Richard I., far from en-
trenching or reining any thing, made still farther encroach-
ments; and thus did the lands continue till the 17th year of
king John; at which time, the grievance being grown
notorious, and generally felt by all degrees of people, divers
noblemen and gentlemen besought the king to grant, that
they might have all those new afforestations made by his
predecessors aforesaid, and by himself, disafforested again;
and the king, after much solicitation, was at length pre-
vailed on to subscribe and seal such articles concerning the
liberties of the forest, as they then demanded; being, for
the most part, such as are now contained in the Charter of
the Forest.

Hereupon choice was made of divers noblemen, &c.
to the number of twenty-five, who were sworn, with others
their affiants, to see the said liberties, so granted and con-
formed by the king, to be in every point observed.

But, before any thing was done to the purpose, king
John died; and king Henry III. succeeding, from solic-
titations were made to him; who, for the better accom-
plishing of the said disafforestation, ordered inquisitions to
be taken, by subialtural juries, for severing all the new
forests from the old; upon which, two commissioners were
sent to take those inquisitions; in virtue whereof, many
great woods and lands were not only disafforested, but were
improved to arable lands by the owners thereof. After
this charter was made and confirmed, some of these new
afforestations were perambulated, and proper inquisitions
taken, and the certainty was determined by matter of re-
cord, which were the old, and which the new: though it
appears, that the greatest part of the new afforestations
were still remaining during the life of king Henry III.

Under Edward I. fresh petitions and solicitations being
set on foot, three bishops, three earls, and three barons,
were at length appointed to see those perambulations per-
formed and continued; who caused them to be made ac-

Thus it appears how the purlieus, or pourallees, had
their first beginning: for all such woods and lands as were
afforested by Henry II. Richard I. or king John, and, by
perambulations, severed from the ancient forests, were, and
yet are, called pourallees, q. d. woods and lands severed
from the old forests, and disafforested by perambulation; pouralle
being the same as perambulatio, in Latin.

But, notwithstanding such new afforestations were dis-
afforested by perambulation, whereby the same became
pouralle, or purlieu, yet they were not thereby so dis-
afforested as to every man, but that they do, in some sense,
continue forest till as to others. For, by the words of
Charter of Forests, if the king has afforested any woods or
lands of his sujeists, to the damage of the proprietors,
they should forthwith be disafforested again; that is, only
as to those persons whose woods and lands they were:
who, as the proper owners thereof, might fell and cut down their
woods at their own pleasure, without any licence from the
king; as also convert their meadows and pastures into till-
age, or otherwise improve their ground to the best advan-
tage. So also they might hunt, and chase the wild beasts
of the forest, towards the same. But no other person
should claim such benefit of hunting in the pouralle, be-
fides the proper owner of the foil thereof, who is left at
liberty to suffer the pouralle to remain forest till, as fore,
in effect, have thought most expedient, because hereby en-
titled to the benefit of the common within the forest, which
otherwise they were excluded from. Hence, if the beasts
chance to wander out of the forest into the pouralle, the
king hath a property in them still, against every man, but
the owner of the ground wherein they are, who hath a spe-
cial property in them, ratiune soli; yet so as he may only
take them by hunting, or chafing with his greyhounds or
dogs, without any forefelling or forestfetting them in their
courte again towards the forest.

Beside what hitherto has been said of the difference be-
tween forest and purlieu, or pouralle, there is this farther
diversity, that all the woods and lands within the regard
of the forest are absolutely within the bondaje or charge of the
forest, as well in respect to the owners thereof, as of any
other person; for no one may cut down his own woods, or
improve his own lands, within the regard of the forest, with-
out licence from the king or his chief justice in eyre of the
forest. Neither shall any person hunt, chafe, or molest
the wild beasts of the forest in his ground, within the regard
of the forest, without licence or warrant from the king, or
his chief justice of the forest to do.

But tho' whole grounds are within the pourallees, are
not subject to these restrinctions. Yet are not the woods
and lands in the pourallees absolutely freed from the bondaje
of the forest, in respect of the wild beasts having their haunts
therein, when they happen to stray out of the forest; but
as they were once absolutely forest, so they are still con-
ditionally so.

Purlieu-Man, or Purlicus-man, or Pouralle-man, is one
who has land within the purlieu, and is allowed or qualified
to hunt or cource within the same, though under certain
restricions.

By Stat. 13 Ric. II. he who may lawfully hunt in any
pouralle, ought to have woods or lands of freehold within
the pouralle, to the yearly value of 40s. By Stat. Jac. I.
he ought to have lands of inheritance of the yearly value
of 10l. or lands of freehold of the yearly value of 30l. or
have
have goods worth 200l. or be the son of a knight or baron, or perilon of a higher degree, or son and heir apparent of an esquire. But, by a later act, Car. II. no man may keep greyhounds within the pourallee, or elsewhere, within England or Wales, unless he have a free warren, or be lord of a manor, or such a freeholder as is defined, in his own right, or in right of his wife, of lands, tenements, or hereditaments of the clear yearly value of 40l. over and above all charges and reprizes of such estate of inheritance; or of lands, tenements, or hereditaments, in his own right, or in right of his wife, for term of life or lives, of the yearly value of 80l. over and above all charges and reprizes, or that is worth in goods or chattels 400l.

The pourallee, or purhain, then, so far as he is to be from him that is so qualified. others, not qualified, and therefore not purhain-men, yet having land in the pourallee, may, if they find any wild beasts in their woods within the pourallee, chace them thereout with little dogs; but not with greyhounds, or other dogs.

Nor is the purhain left at large to hunt at his own discretion; but he is tied down to several rules: as,

1. That he always begins his chase in his own ground; and, that, though he finds such wild beasts in his own pourallee, and in respect thereof, hath a property in them, ratione falsi, against all persons, but the king; yet such his property is only on this condition, that he can lay them with his dogs in chase, without forestalling them, before they can recover the forest. If be they within the limit of the forest, before the dogs falte them, they are the king's, or other owner of the forest.

2. But if the pourallee-man first make his chase in his own freehold, he may purse the fame through every man's ground within the pourallee, and his dogs falte on a wild beast, before he can get within the bounds of the forest, and the beast draw the dogs into the forest, and is there slain by them; here the pourallee-man shall not enter into the forest, nor take the beast so killed, because his course was irregular from the beginning, as he could claim no property in the beast, ratione falsi.

3. A pourallee-man may hunt in his own pourallee with no more company than his own servants; neither may he appoint, license, or warrant any other person, except his servants, to hunt by his commandment in his pourallee.

4. Every pourallee-man is forbidden, by the laws of the forest, to hunt in his own grounds within the pourallee every day, or oftener than three days in any one week, Sunday excepted.

5. Nor is any man to disturb, or make a course after any beast found in his pourallee, within forty days after the king hath made a general hunting in the forest adjoining thereto; because then the wild beasts of the forest come not into the pourallees of their own accord, but as they are forced into the same by the hunters, with clamours, and blowing of horns, so that they fly thither for refuge.

6. No man shall hunt within seven miles of the borders of the forest, or in his own pourallee, within forty days next before the king hath issued out his proclamation, declaring his royal will and pleasure to make a general hunting in that forest.

Inasmuch as the pourallees were once, and in some sense still are forests, it was necessary to have officers to attend, and take on them the charge of the preservation of the game that may happen to wander out of the forest into the pourallees; since otherwise the laws of the pourallees could not be executed, but the forest itself would soon be destroyed by the pourallee-men.

For this reason, rangers were first appointed, who, though not officers in the forest, yet appertain thereto; for all officers in the forest have charge of the vert and venison of the forest; but a ranger hath no charge of the vert, but only of venison coming out of the forest, into the pourallees, his place of charge; from whence his office is to conduct the same back again into the forest.

This officer is appointed by the king, or his chief justice in eyre, and is made by patent, with a fee commonly of twenty, thirty, or forty pounds, or more, by the year, payable out of the exchequer, as also certain fee-deer, both red and fallow, to be taken annually, at proper feasons, out of the forest.

The substance of his oath is, to rechafe, and with his hounds drive back, the wild beasts of the forest, as often as they range out of the forest into the pourallee; to prevent all unlawful hunting and hunting of wild beasts of venery and chase, as well within the pourallees, as within the forest; and to prevent those and other offences, at the next court of attachments or fainmeate, which shall first happen.

Rangers, it is to be observed, belong only to such pourallees as were once the woods and lands of the subject, and were afterwards disafforested again, and so became pourallees. Hence, as there are some forests in England, which never had any enlargement by new afforestations, and therefore have no pourallees at this day, there can be no rangers belonging to them. Manwood's Forest Laws, part 2. c. 70. 4 Inst. 503. 4 Jones's Rep. 278. Moor. 766. 987.

Purmall, in Geography, a town of Hindoostan; 15 miles W.S.W. of Allahabad.

Purmekent, a town of North Holland, on a brook of the same name, governed by a council, bailiff, and burgomasters. The town had a voice in the assembly of the flates; 10 miles N. of Amsterdam. N. lat. 52° 33'. E. long. 4° 46'.—Also, a small island near the coast of Java, in which lies an hospital for the diseased poor of Batavia.—Also, a small island in a large bay on the N. coast of New Guinea. S. lat. 2° 16'. E. long. 135° 12'.

Purna. See Pannaii.

Purnah, a circh of Bengal, bounded on the N. by Morung, on the E. by Dinagepour, on the S. by Raigal, and on the W. by Bahar; about 30 miles long from N.E. to S.W., and 70 from N.W. to S.E. The capital of the fame name is situated on a river which runs into the Ganges; 200 miles N. of Calcutta. N. lat. 25° 40'. E. long. 87° 40'.

Purnitz, a town of Moravis, in the circle of Iglau; 7 miles S.E. of Iglau.

Purparty (Fr. pour part, i.e. pro parte) is that part or share of an estate, first held in common by partners, which is by partition allotted to any of them. To make purparty is to divide and sever the lands that fall to partners, which till partition they held jointly, and pro indiviso. Old Nat. Br. 11.

Purple. Purpur, a scarlet colour, bordering on violet; now dyed chiefly with cochineal.

Purple was much esteemed among the ancients; especially the Tyrian purple, which underwent more dyes than the rest, and which was almost peculiar to the emperors and kings. Yet this purple did not exceed that now in use. The chief reasons why the ancient purple dye has been diffused are, that the latter is both cheaper and finer.

The ancient purple was tinged or given with the blood or juice of a precious turbinated fea-fish, called by the Greeks σαρυγός, and by the Latins purpur; of which we have descriptions in several authors, and shells in most of the cabinets of the curious. See Purple-Fish.
The method of obtaining the colour, Mr. Cole (see Purp.-Fibh) describes thus:

"The shell, which is very hard, being broken, (with the mouth of the fish downwards, so as not to crush the body) and the broken pieces being picked off, there appears a white vein lying transversely in a little furrow or cleft next the head of the fish.

In this vein is the purple matter lodged; some of which, being laid on linen, appears at first of a light green colour; and, if exposed to the sun, soon changes into a deep green, and in a few minutes, into a green, and, in a few more, into a blue; whence it soon becomes of a purplish-red, and, in an hour more, of a deep purple red.

And here the sun's action terminates; but by washing in scalding water and soap, and drying it, the colour ripens to a most bright and beautiful crimson, which will bear washing admirably without the addition of any lye.

While the cloth marked with this colour lies in the sun, it will yield a very strong and fertil smell, as if garlic and asa foetida were mixed together.

The juice which gives this beautiful purple colour is, says M. du Hamel, while it remains in the body of the animal, and while that is in health, wholly white; but no sooner is it exposed to the sun, than it begins to change colour, and in less than five minutes goes through the following changes of pale green, yellowish, and a beautiful emerald green; after this it becomes of a deeper and darker green, then blueish, reddish, and finally a deep and very beautiful purple. Sometimes the juice is found naturally green in the animal: this is probably from the creature's being in a diseased state. But when it is naturally thus, it immediately becomes red, and afterwards purple, on being exposed to the sun; its several preceding changes seeming to have been made already in the body of the animal.

If a piece of linen be rubbed over with this juice, and part of it exposed to the sun, part not, that only will turn red which is so exposed, the other remaining green without any alteration; and it is observed, that the stronger the sun shines, the quicker the change appears, and probably the colour is in proportion also the more beautiful and lively. And it is very remarkable, that if a needle, or any other opaque body, be laid upon the linen which is yet green, and is to become red on being exposed to the sun; after such an exposure, the whole shall be changed red or purple, excepting only that small spot which is covered by the needle, which will still remain green.

A plate of glass, though it be three inches thick, will not prevent the colour from changing purple by being laid over it; but the thinnest piece of metal will keep it wholly green. The one being opaque, and the other pellucid, are evidently the only reasons for this difference.

If the coloured linen be successively covered by three pieces of paper, the one blacked with ink, the other in its natural state, and the third rubbed over with oil, it will change colour on being exposed to the sun in different degrees; and that exactly in proportion to the degree of transparency in each of the papers: most of all in that which was covered with the oiled paper; something less in that covered by the paper in its natural state; and least of all in that which was covered with the blacked paper, as that is least transparent.

The common heat of a fire, or that of a red-hot iron, produces no change at all in the colour when green. The vapour of burning sulphur produces a little; but the green, which had not changed to purple by these experiments, immediately changed to it on being exposed to the rays of the sun.

These experiments were all made in the months of January and February, by M. du Hamel, in Provence; and the sun having power to change the colour so promptly there in these cold months, probably in a warmer climate or season the air would have been sufficient for the purpose, without the open sun; since it seems, from experiment, that both the solar rays, and the light alone in a cloudy day, can act upon this colour. The light and heat of the sun both act on this colour: light is always sufficient to produce the effect, but the heat may easily be too great or too little; and to do the whole in perfection, it must be at a certain middle degree.

This beautiful purple, if it can ever be brought into use in dyeing, will have one very great advantage from its facility. The pieces of cloth that had been stained by it retained their colour, in spite of several boilings in different liquors, which M. du Hamel made them pass through; and the colour, on examination, was found not to be superficial, but penetrated the whole body of the stuff, which was tinged by it. There are many inconveniences which must naturally attend the use of this suffusion as a dye, but they may, perhaps, all be got over by care and application. It is very certain, that it is of too violent a nature easily to penetrate many substances; but it is also certain, that this might be obviated by dissolving it in some proper liquor. It appears very plainly, that the ancients had a method of thus dissolving their purple; but we neither know what was their purple, nor what was its dissolvent: nor, which would be of much more consequence to us at present, what is the proper dissolvent for our own. Mem. Acad. Scien. Par. 1756.

M. Reaumur has also discovered another very different kind of purple. This is produced in oval grains about a quarter of an inch long, full of white liquor bordering on yellow, which cover certain stones or sands, about which the buccina of Poitou usually assemble.

By the experiments M. Reaumur has made, it appears that these grains are neither the eggs of the buccinum, nor the seeds of any sea-plants, nor any riting plants, but the eggs of some other unknown fish.

These grains, being bruised on a white linen, at first only tinge it yellow, and that insensibly; but in three or four minutes they give it a very beautiful purple red, provided the linen be exposed to the open air; for the air of a room, even though the windows be open, will not do. This colour fades however, a little by repeated washings.

M. Reaumur concludes, from the same experiments he made, that the effect of the air on the liquor does not consist in its taking away any particles of it, nor in giving it any new ones, but only in its agitating it, and changing the arrangement of the parts that compose it. He adds, that the liquor of the buccinum, and that of the grains, seem to be nearly of the same nature: except that the latter is more watery, and only saline; whereas the other is hot, and pungent.

P. Labat gives us the description of another purple dye, produced by a tree growing in the Antilles. The juice of this tree, when cut running, is of a blood-red, and communicates the same colour to cloths; though, like the former, it loses much in often washing.

**Purple. Dyeing. See Dyeing.**

**Purple.** In *Medicine*, an epithet applied to every disease, in which eruptions of purple spots, or pustules, appear, and these being usually the accompaniments of fevers of every kind in their worst and most dangerous forms, to *purple fever*
fever was nearly synonymous with putrid, or malignant fever. See PEPITEIS, and PURPURA.

**PURPLE Apple**, in Botany. See Annona.

**PURPLE Fyfh, Purpura, in Natural History, the name of a genus of shell-fysh, the characters of which are these: it is an univalve shell, jagged and bevet from head to tail with spines, tubercles, umbos, or strike. The mouth is small and roundish; the tail is short, and usually the base runs out into a long beak. See Dieying.

It has been usual with most authors to confound together the genera of the murex and purpura, and to use the words as synonymous: but though there is some external resemblance between many of the shells of the two genera, yet they are easily distinguished by this, that the mouth of the purpura is less long, and is less dentated and slanted than that of the murex. The body and the head of the shells of this genus are not so elevated as those of the murex kind, and are not covered with points or buttons at the mouth. If a shell is therefore found to have a small, smooth, and round mouth, and a body covered with undulated leaves, as it were, like those of favorv or endive, and sometimes with long points, and its tail, whether long or short, be hollowed and somewhat bent, this may be called a purpura, and not a murex. Linnaeus makes the purpura a species of the murex.

The ancients distinguished three kinds of purpura; one which had a long and crooked tail, made hollow like a tube or pipe; a second which had either no tail at all, or at the root a very short one; and a third which had no spiral head, or, as we should express it, no clavicle.

On examining the whole family of the purpura, we may distinguish four remarkable specific differences among them. The first of these comprehends those purpurae which have the body of the shell garnished with a fort of undulated foliage in clouded ridges, and have a short and crooked tail. The second comprehends those which have the body of the shell covered with acute points, and have a long tail. The third comprehends those which have as long a tail as the former, but have a smooth body, or at the utmost only have a few flight protuberances and wrinkles on it. And the fourth takes in those which are small, and have an elevated clavicle, a short crooked tail, and the body of which is covered either with slender spines or hairs.

This species of fish, as well as the murex, served among the ancients to dye the fine purple colour they were so fond of, and some of the buccina (e.g. the lapillus of Linnaeus) have been of late found to have the same juice. The purpura and murex are both fished up in great plenty in the gulf of Tarentum; but the small quantity of the coloured juice which each fish contains, and the necessity of using it before the animal dies, makes it impossible to bring it to any regular article of traffic. The ancients used this colour only on cotton and woollen fluffs; whereas our cochineal, which was unknown to the ancients, strikes equally well on silks and stuffs. These shells are also found in various parts of the Mediterranean.

In the seas of the Spanish West Indies about Nicoya, is found a shell-fish, which perfectly resembles the ancient purpura, and, in all probability, is the same fish. This fish, Gage tells us, usually lives seven years; it hides itself a little before the dog days, and continues to disappear for three hundred days running.

They are gathered plentifully in the spring, and, by rubbing one against another, they yield a kind of salvia or thick hair, resembling loft wax: but the purple dye is in the throat of the fish, and the neck part is lodged in a little white vein; the rest of the body is of no use. He adds, that the chief riches of Nicoya consist in this fish. Cloth of Segovia, dyed with it, is sold for twenty crowns the ell; and none but the greatest Spanish lords use it.

There are also found upon the coasts of the South-sea, near the equator, in the neighbourhood of point St. Helena, in the province of Guayaquil, certain sea-finals, as Don Antonio de Ulloa calls them, sticking to the rocks, and covered by the sea at high water, about the size of small nuts, which contain a liquor or juice that has the true colour of purple. The colour is very bright, and so durable, that washing rather increases than diminishes its lustre, nor does it fade or decay by use and wearing. Woven stuffs are not dyed with it, but only cotton threads. As soon as a sufficient quantity of the liquor is squeezed from the fish, the cotton thread is drawn through it, and it takes and retains the tincture without any farther trouble; but the purple colour is not discovered till the thread is dry, the juice being of a milky colour at first, but it soon changes into green, and at last settles in a purple.

Besides the Indian purple fisyhs, we have others much nearer home. In the Philofoph. Transact. o. vol. ii. p. 823, we have an account of purple fish discovered in 1658, by Mr. W. Cole, on the coasts of Somerfetshire, South Wales, &c. where it is found in great abundance. The modern purple fish, Mr. Reaumur observes, is a kind of buccinum, a name given by the ancients to all fishes whose shell bears any resemblance to a hunting-horn; and it appears from Pliny, that part of the ancient purple was taken from this kind of shell-fish: so that this may be esteemed a recovery of what had been supposèd entirely lost. See Dyewing.

The fish, he observes, is good; and adds, that there are several kinds of it differing in size and shell, and also in the colour of the tingling liquor. There are some found on the coasts of Poicliou.

The Caribbea islands have likewise their purple fysh. This is called burgan, being of the size of the end of the finger, and resembling our periwinkles; its shell is of a brownish azure, its flesh white, its intolines of a very bright red, the colour of which appears through the body; and it is this that dyes the froth, which it calls forth when taken, and which is at first of a violet hue, borders on blue.

To oblige them to yield the greater quantity of froth, they lay them on a plate, and shake and beat them against one another, upon which the plate is immediately covered with the froth, which is received on a linen cloth, and becomes purple in proportion as it dries.

P. Labat observes, that if this be the real Tyrian purple, the scent of preparing and fixing it is lost; this colour being found to dwindle and dissipate, in proportion as the linen dried with it is washed.

The purpura lives on other fisyhs. It usually hides itself at a small depth in the sand, sometimes even in fresh-water rivers, and as it lies hid, it thrusts up a pointed tongue, which wounds and kills any thing that comes over it. We frequently find sea-shells with round holes bored through them, as regularly as if made with a boring instrument; these are generally allowed to be made by the tongue of the purpura, in order to its feeding on the fish within.

The purpura has two horns like that of a snail; and Fabius Columna says, that they have eyes in these, not placed at the ends, as in the snail, but in the middle of each horn.

The purpura is a shell-fish very well known, and has been known also in almost all times to afford a purple liquor; but there has been no method discovered of bringing this li-
pur into use in dyeing, the fibre has been neglected, and its juice never attempted to be brought into use.

**Purple-Wort**, in Botany, a name given to several species of trefoil.

**PURPRESTURE**, in our *Ancient Law Books*. See *PurerspreSTURE*.

**PURPRISMUS**, of the French *purpuris*, denotes a close, or inclosure: also the whole compass or extent of a manor or place.

“*Donavi eis meum purpurum de Kirkeham, & domos meis, & molendinum, & prata, &c.*” Charta Walteri Eipec. Priorat de Kirkeham.

**PURPURA, Persian**, the name with the Perian shell, a species of dolium.

**Purpura**, in *Medicine*, in the nomenclature of cutaneous diseases proposed by Dr. Willan, signifies an eruption of purple specks and patches, that is of *petechia, ecchymomata, and violae*, accompanied with general debility, but not always with fever. Under this limitation, the purpura is synonymous with the "petechiae fine febres" of some medical writers, (see Rombergius, *Ephym. Natur. Carofo. dec. iii. ann. 9 and 10. obi. 108; and Dr. Graaf, Diff. Inaug. de Petechiae fine Febere, Göt. 1775;) with the "hemorrhham petechialis" (see Dr. Adair, Diff. Inaug. Edin. 1789, and Dr. Bateman, Diff. Inaug. ibid. 1801;) with the "landfeerwysse," &c. of others. Riberius, Dimerbroeck, Sauvages, Cullen, and one or two others. appropriated the term purpura in like manner to petechial spots only, and rightly excluded from this appellation all other eruptions of a character essentially different.

In thus limiting the acceptation of the term, however, it is proper to mention, that in the writings of many physicians it is applied to various other eruptive diseases, which have no affinity with petechial blotches, and very little with each other. Thus, under the name of purpura, the red gum, or fibruphulis, is described by Etmüller,—the leprous fever by Schultz and Juncker,—the mealls by Hafenreffer and Morton,—the nettle-rash, military vehicles, and Echen, by Hoffmann and others. See Willan on Cutan. *Diff.* p. 452.

The purpura occurs under various degrees of violence, which induced Dr. Willan to make two species, which he denominated *fimplis* and *hemorrhagicum*, according as the eruption occurred alone, or with discharges of blood. It is impossible, however, to draw a distinct line, where nature presents no clear difference. We can only state that, in the milder degrees, there is an eruption of petechial only, chiefly appearing on the extremities and breast, and seldom affecting the face. The complexion is generally pallid or hollow, and there is a considerable degree of debility and languor, and sometimes pains in the limbs.

In the more severe cases of the disease, the failure of strength is considerably greater, and often precedes, for some time, the appearance of the eruption. The spots commonly appear first on the legs, where they are usually the largest and most numerous, and are often accompanied with anacous feevings. When they first appear, they are of a bright red hue, but they gradually become purple or livid, and when about to disappear, they change to a brown or yellowish hue; and in the progress of the disease, as the spots appear and fall in succession, the skin presents a considerably variegated appearance. In the more severe forms, the petechiae are intermixed with *ecchymosae* and *violae*, or livid patches and stripes, resembling the effects of a bruise, or of the strokes of a whip. In this latter, sometimes, when these patches do not appear spontaneously, the gentlest pressure on the skin, such as is applied in feeling the pulse, will produce a purple blotch, like that which follows a severe blow.

When the disease is still more severe, in addition to these effusions of blood under the cuticle, considerable discharges of blood take place from those parts which are defended by a very delicate cuticle; whence these haemorrhages originate particularly from the internal passages and organs, and are occasionally very profuse, endangering, and occasionally destroying life. Most frequently, however, the bleeding is small, and in small quantity, sometimes even a constant oozing, and sometimes returning at intervals. These hemorrhages take place from the gums, nostrils, throat, the inside of the cheeks, the tongue, and lips; sometimes from the lining membrane of the eye-lids, the uvea, and the external ear; and often from the internal cavities, the lungs, stomach, bowels, kidneys, uterus, and bladder. There is great variety, however, in the periods of the disease at which the hemorrhages commence and cease, and as to the proportion which they bear to the cutaneous effulence.

This singular disease occasionally appears suddenly, in the midst of good health, attacking during the night. It is always accompanied by great feebleness and depression of spirits; and often by pains in the head, loins, or abdomen, by irregularity of bowels, or by cough; and the pulse is sometimes slightly quickened and very feeble, as in a moderate hectic. But in some cases these functions are not perceptibly disturbed. The duration of the disease is equally uncertain: in some instances it has terminated in a few days, while in others it has continued not only many months, but years. When it terminates fatally, it is commonly in consequence of a copious hemorrhage, either suddenly from some important organ, or more slowly from several parts at the same time.

The causes of this disease are not clearly ascertained, nor its pathology well understood. It occurs at every period of life, and in both sexes; but most frequently in women, and in boys before the age of puberty, particularly in those who are of a delicate habit, who live in close and crowded situations, and on poor diet, or are employed in sedentary occupations, and subject to grief, anxiety, fatigue, and want of sleep. It has likewise attacked those who are left in a state of debility by previous acute and chronic diseases, as erysipelas, or small pox, and sometimes in the puerperal state, or after violent labours from miscarriage. On the other hand, however, the disease appears occasionally in its most fever and fatal form, where none of these circumstances had previously existed: for instance, in young persons living in the country, and suffering no privation of any of the comforts of life, and previously enjoying good health. This fact tends greatly to obscure the pathology of the disease: for it renders the operation of these alleged causes extremely questionable, and seems to establish an essential difference between purpura and fevery, in the origin and nature of the morbid actions which constitute the disease. In fevery (by which we mean the *febrilus*, or true fevery, formerly prevalent among seamen in long voyages, and among people in besieged towns, and other situations, when living upon patrid, salted, dried, or otherwise indigestible food, yielding imperfect nutrition,) the restoration of the proper nourishment, with the use of fresh vegetables and acids, invariably removes the symptoms, and they never commence where such diet can be obtained: while, in many cases of purpura, this diet has been taken abundantly, without the smallest alleviation of the complaint, and the disease has come on, where there had been no deficiency. *On the other hand, the rapidity of the*
PUR

the attack, the acute and often very severe pains in the internal cavities, the actual inflammatory symptoms that sometimes supervene, the occasional removal of the disease by spontaneous hemorrhage, the frequent relief derived from artificial discharges of blood, (see two cases of purpura by Dr. Parry, Edin. Med. and Surg. Journ. for Jan. 1809), and from purging, all tend to excite a suspicion that some local visceral congestion or obstruction is the cause of the symptoms in different inferences." (Bateman’s Practical Synopsis, of Cutan. Diff. p. 110.) Several facts in proof of these observations are stated in the work just quoted; but a sufficient number has not yet been collected to afford any general inference respecting the nature of the disease.

The cure of purpura is, therefore, not established upon any clear principle, and there has been considerable difference of opinion upon the subject. Dr. Willan has given a very imperfect view of this point. All that he says relative to the cure of the work form of purpura, is compressed in these few lines. "In the treatment of this disease, we should recommend moderate exercise in the open air, a generous diet, and the free use of wine, Peruvian bark, vitriolic acid, &c. Without air, exercise, and an easy state of mind, the effect of medicines is very uncertain." (On Cutan. Difeaes, p. 461.) Of this, indeed, he has given an ample proof in the next sentence, where he tells us that a patient "took for two or three months Peruvian bark in considerable quantities, the vitriolic and marine acid, and wine, without much advantage." In truth, the cure of purpura is, we believe, not to be effected by these means. In the lighter degrees of the disease, occurring in children who are ill fed and nurfed, and excluded from the air and from all exercise, these spots may seem to do good, when combined with air and exercise. "But," as Dr. Bateman observes, "when it occurs in adults, especially in those already enjoying the benefits of exercise in the air of the country, and who have suffered no privation in respect to diet; or when it appears in persons previously stout, or even plethoric; when it is accompanied with a white and loaded tongue, a quick and somewhat sharp, though small, pulse, occasional chills and heats, and other symptoms of feverishness, however moderate;—symptoms which may be presumed to indicate the existence of some local congestion;—then the administration of tonic medicines, particularly of wine, cinchona, and other warmer tonics, will be found efficacious, if not decidedly injurious. In such cases, fresh and repeated evacuations of the bowels, by medicines containing some portion of the muriate of mercury, will be found most beneficial. The continuance or repetition of these evacuations must, of course, be regulated by their effects on the symptoms of the complaint, or on the general constitution, and by the appearance of the excretions from the intestines. If the pains are severe and fixed, and if the marks of febrile irritation are considerable, and the spontaneous hemorrhage not profuse, local or general blood-letting may doubtless be employed with great benefit, especially in robust adults." Præct. Synopsis, before quoted, p. 114.

The importance of free purgation in purpura has been clearly stated in a short but valuable communication from Dr. Harty, of Dublin, published in the Edinburgh Medical and Surgical Journal, for April, 1815: in more than a dozen cases treated in this manner by Dr. Harty, the hemorrhages ceased, and the purple spots disappeared, after a few doses of calomel and jalap had been taken. In the two cases related in the same useful journal by Dr. Parry, of Bath, before alluded to, and which were speedily cured by two bleedings from the arm, the blood drawn exhibited a tenacious contracted coagulum, covered with a thick coat of lymph, as in diseases of an inflammatory nature. The patients were a lady and an officer, the latter of whom was accustomed to free living; in both cases some degree of feverishness accompanied the purpura.

There is one variety of the disease, which Dr. Willan distinguished as a third species, by the title of purpura urticans, because the eruption commences in the form of rounded and reddish elevations of the cuticle, resembling the wheels of nettles or rashes; but they are not accompanied by the same sensations, tingling and itching, which belong to the nettle-rash. These little tumours gradually dilate; but within one or two days they subside to the level of the surrounding cuticle, and at the same time their hue becomes darker and at length livid, or purple. As these spots are not permanent, but appear in succession in different places, they are commonly seen of different hues; the fresh and elevated ones being of a brighter red, while the level spots exhibit different degrees of lividity, and become brown as they disappear. They are most common on the legs, where they are frequently mixed with petechiae; but they sometimes appear on other parts of the body.

The duration of the purpura urticans is various, from three to five weeks, in the course of which time the hands and ankles are affected with edematous swellings: there is also a distressing degree of languor and debility, and a loss of appetite, but seldom hemorrhage. It generally appears in winter and autumn, affecting those who are exposed to fatigue, and live on poor diet, and delicate young women of indolent and luxurious habits. The same precepts, as to treatment, are applicable to this as to the other varieties of purpura.

When purple spots occur as symptomatic of bad fervers, they require no peculiar treatment. They are much less frequent cosomitants of fevers than they were formerly; a circumstance which is probably to be ascribed partly to the more liberal use of purgatives at present in all febrile diseases, and partly to the more free admixture of fresh air, to the superior cleanliness, &c. now observed in these maladies. The appearance of these spots has been occasionally noticed by various authors in agues, remittent fevers, palies, dropsy, and atrophy. Dr. Willan observes, that in the list flage of pulmonary consumption they sometimes occur as the immediate forerunners of death. (See Perry's Pract, Synopsis.) For histories and cases of purpura, see Ducuing's Med. Comment. vol. vii. and xxxvii. and Med. Cafees and Obs. p. 90. Annals of Medicine, vol. ii. Memoirs of the Med. Society of London, vol. iii. art. 20; and vol. iv. art. 17. Medical Traits and Obs. vol. ii. Willan's Reports on the Difeases of London.

PURPURATI, in our Ancient Historians, denote the sons of emperors and kings.

PURPURE, PURPURE, or Purple, in Heraldry, according to fume, is one of the five colours of armories, mixed or compounded of gules and azure, bordering on violet; and, according to others, of a little black and much red colour. It is, by the heralds, supposed a symbol of temperance, liberality, dignity, authority, faith, and piety. Most authors in heraldry, as Fayan, Geliot, Monet, and Memfrer, do not allow purple for a colour, in regard it is not simple, but composed of a mixture of other colours. They rather esteem it a kind of intermediate tinture, sometimes metal, and sometimes colour; hence the Spaniards call it una miilion: fo that one cannot lay it on metal and colour without falsifying the arms.

Add, that many take the purple, as it is accounted, on many ancient bearings, by which some of the moderns would
evince the regularity and legitimacy of this colour in armery, to be no other than silver tarnished.

Spelmann, however, in his Apologia, allows purple the preference before all other colours, as having been an enigma of royalty for many ages; yet even he allows it to have been excluded, by the ancient heralds, as only an imperfect colour.

It is represented in engraving, by diagonal lines drawn from the finisher chief to the dexter base point. In the coats of noblemen it is called amethyst; and in those of princes, Mercury.

PURPURANA, a name used by Caneparius, and some other authors, for the aurum mofiacum, or aurum mufium of the shops, the present preparation of which differs from that of that author only in the proportions of the ingredients.

PURPURISSUS, in the Ancient Writers, both Greek and Roman, the name of a compound colour or focus of a fine purplish red, used to paint women's cheeks.

It seems by the composition to have been somewhat like our rose pink, as it is called by the colourmen. It was made of the creta argentaria, or fine white kind of chalk, disloved in a strong purple tincture of some of the roots of wood which dyed red; and when the coarser part was subdued to the bottom of the vessel, the liquor, while yet thick, was poured off into another vessel; and what subdued from this, which was as fine as flour, was of a beautiful pale purple, and was the purpurissus favored for use.

PURREL, anno 35 Eliz. cap. 10, a lift ordained to be made at the ends of kerfeyes, to prevent deceit in diminishing their length.

PURRONGUR, in Geography, a town of Hindooftan, in the circuit of Bilfa; 20 miles S.E. of Bilfa.

PURROWNAH, a town of Hindooftan, in Oude; 23 miles E. of Goora-pour. N. lat. 26° 57'. E. long. 84° 17'.

PURRUNUH, a small circuit of Bengal, about 16 miles in circumference; N. of Mauldhur. Also, a town of Bengal, and chief town of the said circuit; 26 miles E.S.E. of Burdwan. N. lat. 23° 4'. E. long. 88° 27'.

PURSAH, a town of Hindooftan, in Bahar; 18 miles N. W. of Chupra.

PURSAUMBAH, a town of Hindooftan, in Bahar; 35 miles E. of Durbangah.

PURSE, a manner of accounting; or, as some call it, a species of money of account, much used in the Levant, particularly at Constantinople, where it is 500 apers; three apers being equal to a para, and forty paras equal to a piastre, called by the Turks grouch, and by the Lughth dollar. By the regulations of 1780, the purse of 500 piastres was to weigh 28 12½ Turkish drams. A single piastre weighed 5½ drams, or 277 English grinds; and the other pieces in proportion. Their standard of fineness was reduced at the same time to 50 carats (or hundredth parts) of fine silver, and 50 of alloy; which gave the value of the piastre at 194½ sterling, and the other silver coins in proportion. But since that period the Turkish coins have undergone a deterioration, so that a piastre of the latest coinage being weighed and assayed by the king's assay master of the Mint, appeared to be in weight 8 dwt. 6 gr. in fineness, 5 oz. 6 dwt. worse than the English standard. This gives its fineness 47 carats 2 grams Turkish, and its value, in sterling, 13d. Kelly's Un. Cambill.

This money of account is called purse, because all the grand signior's treasure in the seraglio is kept in leather bags of this value.

In this, however, there is some difference; for the purse in Egypt is 25,000 medinys, or 75,000 apers; and in other parts of Turkey it is only 20,000.

This method of accounting the Turks derive from the Greeks, and they from the Romans; the emperors of which brought it to Constantinople, as appears from a letter of Constance to Cicellian, bishop of Carthage, quoted by Eutropius and Nicephorus. See FOLLIES.

PURSE-Net, in Rural Economy, a net used for taking both hares and rabbits at certain times; and three or four dozen of them are sufficient to lay over their holes: they are to be fastened, by tying strings to ficks thrust into the earth, otherwise when the rabbits bolt out, they will run away and get out of the nets; but when the nets are fixed, and all things are in order, there must be one or two per sons to lie close, to see what game comes home; while, in the mean time, you beat the bushes, to force them homewards. But another way to take rabbits with these nets is, at their coming out of their parraces; and they should be secreted in this manner. First hunt them up and down, to force them all in, then put in a ferret, with a bell about her neck, which gives the rabbit notice of her coming, who, in endeavouring to avoid the ferret, runs into the net.

PURSER, an officer aboard a man of war, appointed by the lords of the admiralty, who receives her victuals from the victualler; and is to take care that it be in good condition, and well laid up and flowed. He is also to see that they are carefully distributed to the officers and crew, according to the instructions which he has received from the commissioners of the navy for that purpose. To him also belongs the distribution of hoes, &c.

He is also to keep a list of the men and boys belonging to the ship, and to set down, exactly, the day of each man's admittance into pay; that the paymaster or treasurer of the navy may relieve out his disbursements, and pay off the men according to the muster-book.

PURSIVENESS, or PURSENESS, among Farriers, thick-ness of wind, a name common to all those diseases in horses which arise from obstructions in the passages of the lungs. Purse-needs, sometimes also called broken wind, may proceed from an ulcer, or some inward wailing of the lungs, in which the small vessels are worn or abraded by the sharpness or acrimony of the common discharges.

The like disorder may also arise from a flagitation, hindering the air from penetrating so as to lift up the lungs in the act of respiration; or from some tough and mucilaginous matter separated in the branches of the wind-pipe.

The usual occasions are cold, surfeits, and other diseases not thoroughly carried off. Purse disorders may also arise from unwholesome food, bad air, and hard riding when a horse is full. The signs are commonly a heaving and beating of the flanks; a wheezing and rattling. Sometimes the kernels about the throat will swell, and there will be a glandulous running at the nose, which is the utmost flag of the disease, and usually reputed desperate.

Pursuant, See PURSUIVANT.

Pursur, in Geography, a town of Hindooftan, in Oude; 13 miles N. of Mahomdy.

Purger, Anthony, in Biography, was born at Up-
Pur

Hurborn, in Hampshire, about the beginning of the 18th century. His education was extremely limited, but he exhibited a striking proof of his capacity for learning while he was very young; for, being prevented by illness from attending school almost six weeks, he applied, by himself, during that time, with such diligence and success to the study of arithmetic, that upon his return to school he was able to explain the proceedes of evolution to his master, whose attainments had not carried him so far. At this time of life he exhibited great powers of memory, by committing to it twelve of the longest chapters in the bible in as many hours. He was put apprentice to a shoemaker, who was also a dealer in sheep, and employed Anthony a good deal in looking after his flock. This was not by any means an irksome business, as it afforded him an opportunity for reading the scriptures, to which he was particularly attached. As he advanced in years, he found that his favourite book contained doctrines that were very differently interpreted by different persons, and he was resolved to study the Old and New Testament in their original languages. Having renounced the occupation for which he was originally intended when he was about twenty years of age, he commenced teacher in a school, but afterwards removed to London, for the sake of more easily acquiring the means of prosecuting his studies. Here he probably refixed in 1727, when he published his work, entitled "The Youth's Delight." While at London he became a Quaker, and officiated among the friends in the character of a minifter. He returned to Hurborn, and refixed his school in 1727, and probably continued it for some time, during which he began to translate the books of the Old Testament, from the original Hebrew. While thus employed, he felt it his duty to become a missionary, and travelled through several counties of the kingdom, till he came to Stambrook, near Bristol, towards the latter part of the year 1738. Here he refixed at the house of a maltster, whose son he instructed in classical learning, while he devoted his leisure to his favourite employment of translating the scriptures. In 1746 he made an attempt to publish his translation of the Old Testament in numbers; but for want of encouragement he did not proceed beyond two or three numbers. When he had completed the translation of the whole bible, he could find no bookseller who would embark in the publication. Thus was the labour of thirty years likely to be lost, till Dr. Fothergill made him a present of 1000l. for the copy, and took upon himself the expence of printing the work. Under his auspices, it made its appearance in the year 1764, with the title of "A New and literal Translation of all the Books of the Old and New Testament, with Notes critical and explanatory," in 2 vol. folio. It was the author's intention to have published a second edition, with various corrections and alterations, but he did not live to accomplish the design. He died in 1777, about the age of 75. Purver was described by Dr. Fothergill as "a man of great simplicity of manners, regular conduct, and a modest reverence: he is steadily attentive to truth, hates falsehood, and has an unconquerable aversion to vice; and to crown the portrait, he is not only greatly benevolent to mankind, but has a lively sense of the divine attributes, and a profound reverence of, and submision to, the Supreme Being."

Gent. Mag.

PURVEYANCE. See PURVEYANCE.

PURVEYOR. See PURVEYOR.

PURVIEW, from the French, pourvu, a gift, grant, provision, &c. a term frequently used, by Sir Edward Coke, for the body of an act of parliament, or that part which begins with Be it enacted, &c. as contradistinguished from the preamble.

The statute of 3 Hen. VII. stands upon a preamble and a purview. 12 Rep.

PURULENT, PURULENTUS, in Medicine, something mixed with, or partaking of, pus or matter.

Pithecus, Pithecus, a pithecus matter. In a dysentery, the filous are purulent: when there is an ulcer in the reins or bladder, the wine is purulent.

PURUSH, PUS, in Mythology. See PURUSH.

PURUZ, in Geography, a river of La Plata, which rises about S. lat. 17° 20', taking the name of "Rio Beni," and afterwards called "Amaru-Mayu," or "The Serpent," from S. lat. 12° its course is not ascertained till it comes to S. lat. 6°, after which it assumes the name of Puruz, and runs into the river of the Amazonas, or Maranon, S. lat. 3° 44'. W. long. 45° 6'. Its whole course is northerly about 800 miles.

PURWAR, a town of Hindoosfan, in Lahore; 14 miles S. of Scalcot.

PURYSBURG, a handsome town of South Carolina, in Beaufort district, which district contains 25,887 inhabitants, on the E. side of Savannah river, 37 miles from the ocean, and 20 from Savannah. It derives its name from a Swiss, John Peter Purry, who settled a colony of his countrymen here about the year 1735, with a view to the culture of silk. The mulberry-trees are still standing, and some attention is paid to the raising of silk. The town contains between 40 and 50 dwelling-houses, and an episcopal church; 64 miles W.S.W. of Charleston. N. lat. 32° 25'. W. long. 81° 12'.

PUS, from Latin, matter, the fluid contained in abscesses, and discharged from ulcerated surfaces, and sometimes from membranes surfaces which are merely inflamed, and quite free from ulceration, as is illustrated in cafes of gonorrhoea, empyema, &c. Pus is formed by a peculiar process, which is termed putrefaction, of which we shall have occasion to speak in a future volume of this work.

In the present place, we shall content ourselves with inserting a few observations on the qualities and uses of pus, chiefly taken from the writings of Mr. Hunter.

True pus has certain properties, which, when taken singly, may belong to other secretions, but which, conjointly, form the peculiar character of this fluid, viz.: globules swimming in a fluid, which is coagulable by a soluton of salt ammoniac, which no other animal secretion is, and, at the same time, a consequence of inflammation.

The colour and the consistence of pus are the two qualities which first attract the notice of every, the most superficial, observer. The colour arises from the largest portion of this fluid being composed of very small round bodies, very much like those little globules which, swimming in a fluid, make cream. The fluid in which the globules of pus swim, we might at first suppose to be the serum of the blood, for it coagulates with heat, like the latter fluid. Pus is also probably mixed with a small quantity of coagulating lymph; as it partly coagulates after it is secreted.

The fluid part of pus, however, is known to have properties which ferum has not. There being a similiarity between pus and milk, experiments have been made to ascertain whether the fluid of pus could be coagulated with the garlic juice of animals; but no coagulation could be effected in this manner: a solution of salt ammoniac made the fluid part of pus coagulate; but not any other secretion, or
or natural fluid; and hence it was concluded, that whenever globules were found swimming in a fluid, coagulable by alkali in a solution, the matter was to be considered as pus.

The proportion which the white globules bear to the other parts of pus, depends on the health of the parts producing the discharges. When the globules are very abundant, the matter is thicker and whiter, and is called healthy pus; the meaning of which is, that the solids, which produced it, are in good health; for these appearances in the matter are no more than the result of certain salutary processes going on in the solids, the effect of which processes is to produce the dispositions, on which both suppuration and granulation depend.

Pus is specifically heavier than water, and is probably about as heavy as blood.

Besides the above properties, pus has a sweetish mawkish taste, very different from that of mucus, and of the same taste takes place, whether it is pus from a sore, or an irritated inflamed surface.

Pus has a smell in some degree peculiar to itself; but this differs in different cases. Some diffeces, it is said, may be known by the smell, as, for instance, a gonorrhoea.

Pus sinks in water; mucus floats. Pus communicates to water an uniformly troubled white colour; mucus gives the appearance of stringy portions floating in it. Mucus is said to be more readily diffusible by sulphurous acid than pus is. It has also been asserted, that if water be added to such solutions, the pus is precipitated to the bottom of the vessel; while the mucus, instead of being completely precipitated, forms undissolved flakes. A solution of caustic alkali diffuses both pus and mucus; but when water is added, the pus is said to become separated, but not the mucus.

Though solutions in chemical medicine and precipitations have been thought a test of the distinction between these two fluids; yet the method has been thought absurd and unphilosophical. It has been conceived, that all animal substances whatever, when in solution, either in acids or alkalies, would be in the same state, and therefore, that the precipitation would be the same in all. Carcinaceous earth, when diffused in muriatic acid, is in that acid in the same state, whether it has been diffused from chalk, limestone, marble, or caracinaceous spar, and precipitations from all are the same.

Hence experiments were made on organic animal matter, such as mucus, tendon, cartilage, liver, and brain; and on inorganic, such as pus and the white of an egg. All these substances were diffused in sulphuric acid, and precipitated with the vegetable alkalies. Each precipitation was examined with such magnifiers as plainly shewed the forms of the precipitates, all which appeared to be flaky substances. The precipitate by the volatile alkalies had exactly the same appearance. The same appearances were seen when the above kinds of animal matter were diffused in the vegetable caustic alkalies, and precipitated with the muriatic acid. A flaky substance, void of any regular form, composed each precipitate.

Pus does not irritate the particular surface which secretes it, though it may be irritating to any other. Hence no suppurating surface, of any specific kind, can be kept up by its own matter.

If this had not been the case, no fore of a specific quality, producing matter of an irritating kind, could ever have been healed. This is similar to every other secretion of stimulating fluids, as the bile, tears, &c., which fluids do not stimulate their own glands or ducts, but are capable of stimulating any other part of the body.

Whenever a real disease attacks either the suppurating surface or the constitution, the production of true pus ceases, and the fluid becomes changed in some measure, in proportion to these morbid alterations. In general it becomes thinner and more transparent, and it partakes more of the nature of the blood, as is the case in most other secretions under similar circumstances. Sudden is the term usually applied by surgeons to pus in this degenerated state. This unhealthy fort of matter has more of the serum, and frequently more of the coagulating lymph in it, and less of the combination, which renders it coagulable by a solution of alkali. It has also a greater proportion of the extraneous parts of the blood, which are soluble in water, such as fats; and it has a greater tendency than true pus to become putrid. Such unhealthy matter may even be irritating to the surface which produces it.

The discharge, when of an irritating fort, is more stimulating to the adjoining parts with which it comes in contact than to its own secreting surface. In this manner it frequently produces excoration of the skin and ulceration. Thus the tears exorate the skin of the cheek, in consequence of the quantity of fats which they contain. From this effect, matter has been called corrosive, a quality which it has not: the only property which it possesses being that of irritating the parts which it touches, in order to cauze their absorption.

When the vessels thus lose the power of producing good pus, they also lose more or less the power of forming granulations. This may depend on innate deviation from the due structure and action which such vessels should possess, in order to be qualified for the performance of these two operations.

Pus from several circumstances, would appear in general to have a greater tendency to putrefaction than the natural juices have; but, perhaps, this is not the case with purus, which, when first discharged from an abfece, is commonly perfectly sweet. There are, however, some exceptions to this, but these depend on circumstances entirely foreign to the nature of pus itself. Thus, if the abfece had any communication with the air, while the matter was confined in it; or if the collection has been too near the colon, or rectum, as to have been affected by the feces, then we cannot wonder that the matter should become putrid.

When blood is blended with pus, when flours are mixed with it, when the parts forming the seat of the abfece are in a gangrenous state from an erysipelas affection; the matter has a greater tendency to putridity than the pure pus discharged from found abfeces, or healing fore. Pure matter, though easily rendered susceptible of change by extraneous additions, is in its own nature tolerably uniform and immutable. It appears so unchangeable, that we find it retained in an abfece for weeks, without having undergone any alteration. These qualities, however, only belong to perfect pus.

In the preceding paragraph it is stated, that matter remains very often unchanged in abfeces for weeks. This expression of Hunter’s is not strictly correct; for it is well known, that the surfaces of the cavities of abfeces are always absorbing, as well as secreting ones; consequently there must be a continual mutation going on in the contained matter.

When there are disced bones, or other extraneous bodies, exciting irritation, sometimes even to so great a degree as to make the vessels bleed, and often wounding the vessels of the parts, the matter is always found to be very offensive. This state of the discharge is one mark of a diseased bone.

The
The discharge of an unhealthy sore blackens silver probes, and preparations of lead. This effect is imputed by Dr. Crawford to the sulphured hydrogen gas generated in the matter. Phil. Trans. vol. lxxx. for the year 1790. p. 301, &c.

**Use of Pus.**—By some it is supposed to carry off humours from the constitution. Suppuration is sometimes regarded as a constitutional disease, changed into a local one, which constitutional malady is discharged, or thrown out of the body, either in the form of pus, or together with this fluid. Critical abscesses have been thought to be cafes of this sort. Suppuration has also been imagined to carry off local complaints from other parts of the body, on the old principle of derivation or revulsion. For this reason, fores or illies are made in found parts before allowing other fores to be dried up. Suppuration is sometimes excited with a view of making parts, such as indurated swellings, dissolve into pus; but we have endeavoured to shew that no disollution of the folids is concerned in the production of pus.

A secretion of pus is looked upon as a general prevention of many, or of all, the causes of disease. Hence illies are made to keep off both universal as well as local diseases. However, the use of pus is perhaps unknown for it is formed most perfectly from healthy fores, and in healthy constitutions; and large discharges from parts not very essential to life, produce very little change in theconstitution, and as little upon being healed up, whatever some may suppose to the contrary.

This is certainly the case with many old ulcers, the suppuration from which seems to have little or no effect in impairing the health. Nor is there any real reason to be afraid of healing such ulcers, when possible, lest a worse disease should follow from the stoppage of the discharge, to which the sytem is supposed to be habituated so much, that the continuance of such discharge is essential to health.

Every one knows, that when there is no interference of art, that is, when the surface of a sore is left uncovered, the thin part of the matter evaporates, and the thick part dries and forms a scab. Nature, therefore, seems to have designed, that one use of pus should be to make a cover or protection for ulcerated surfaces.

Among the secondary uses of suppuration may be mentioned, opening a communication between a disease and the external surface of the body; forming a pallage for the exit of extraneous bodies, &c.

**PUSA,** in Geography, a town of Hindoostan, in Bahar; 32 miles E. of Haipour.

**PUSBACH,** a town of Germany, in the principality of Culmbach; 12 miles S. of Culmbach.

**Puschenga,** a river of Ruflia, which rises in lake Urs, in the government of Archangel, and runs into the Pinaera near Kevrol.

**Puschavo,** a town of Switzerland, in the Grisons, which is derived from the name of one of the jurisdictions ceded by the duke of Milan, in the year 1456. The greatest number of the inhabitants conris of Latin Catholics. The town lies three miles N. of a lake of the same name, abounding in fish, and distant 14 miles S.W. of Bormio, and is situated 17 miles W.S.W. of the same town, and 20 miles E. of Chiawenna.

**Puschima,** a town of Ruflia, in the government of Novgorod; 40 miles N.N.E. of Biebozzerk.

**Pushan,** in Mythology, a name for Surya, a personification of the sun, among the Hindus, and a name also of their god Siva.

**Pusheng,** in Geography. See Kooshinjee.
exaggerated by the eastern dialect, that there is not much to be expected from them.

PUSULA, in Geography, a town of Sweden, in the province of Nyland; 37 miles N.N.W. of Helsingfors.

PUT, in the Manege, called in French métiers, is used for the breaking or managing of a horse: thus,

To put a horse to corsets, or capricies, is to teach him those parts of the manege.

To put a horse upon his haunches, called in French affaires, is to make him bend them handomely in galloping in the manege, or upon a stop. See HANACHES.

To put a horse to the walk, trot, or gallop, is to make him walk, trot, or gallop.

To put a horse under the button, see BUTTON.

PUTAGE, Putagium, in our old Lazio Books, denotes whoredom or fornication on the part of a woman.

The word is formed from the French putte, whore; putagium, q. d. putam agere. "Quod autem generaliuer Met dies, putagium hereditatem non admite; illud intelligendum est de putagio matris; quod illius Ixeres legitimatos ed, quem nuptis demonstrat." Glos. lib. vii. cap. 12.

PUTALIA, in Geography. See PUTELLA.

PUTALLOM, a town on the coast of Ceylon, near Calpenteen, remarkable for its falt-pans. This place, before the arrival of Europeans on the island, supplied the natives with salt; and on account of its convenient situation, was pitched upon by the Dutch for the manufacture of the salt with which they supplied the king of Candy's dominions, according to the articles of their treaty with him. The falt-pans are formed by an arm of the sea which overflows part of the country between Putallom and Calpenteen.

A very large quantity of salt was manufactured here by the Dutch; they looked upon it as of the highest importance to their interests in the island, and the most formidable weapon which it was in their power to employ against the native king, as it was impossible for him to procure any but through their means. Since the British have obtained possession of the island, this manufacture has been almost entirely neglected. It is capable, however, of being rendered very profitable, as it is the only one of the kind on this side of the island, and the most conveniently situated for supplying the king of Candy's dominions. The Dutch enacted very severe laws to prevent individuals from manufacturing or trading in this article; the government taking upon itself the management of the works, and the care of supplying both its own subjects and the Canadians. In order to keep a constant check on the latter, the Dutch were careful not to allow them too great a quantity at once; and whatever remained at Putallom, after supplying the demands of each year, they destroyed, that it might not be seized upon by forprife.

PUTANGES, a town of France, in the department of the Orne, and chief place of a canton, in the district of Argentan; nine miles N.W. of Argentan. The place contains 502, and the canton 11,934 inhabitants, on a territory of 2125 kilometres, in 31 communes.

PUTANISME, Putanism, an Italian term, naturalized by some English writers, signifying whoredom, or the life or condition of a courtier.

The word we borrow immediately from the French, putaniu/me; and they from the Italian putanna, whore; of putta, girl.

PUTAO, is Geography, a town on the S. coast of the island of Luçon. 8. lat. 13° 6'. E. long. 123° 28'.

PUTATIVE, Suppositive, something reputed to be what it really is not.

The word is seldom used but in the phrase putative father.

Thus we say, Joseph was the putative father of Jesus Christ.

PUTAVERI, in Biography, a native of Otaheite, brought into France by the circumnavigator Bougainville: of whom a gentleman, who had refided a considerable time in Italy, and was an excellent judge of music, affured us that the effects of French music, when fairly tried upon him immediately on his arrival, were not those of rapture, but ridicule. He danced to it, indeed, as we would to a marked measure beat on a drum or a table; for as soon as he returned from the great opera, whither he was carried, he mimicked what he had heard and seen in the most natural and ridiculous manner possible; giving the company a specimen of the French opera, which was the most admirable parody imaginable of French singing, or rather of the screams and howlings at the Académie Royale de la Musique in the time of Louis XV. Our friend wished to try the effects of Italian music upon this demi-native of Otaheite; but there was no opportunity, for how could it be properly executed at Paris? However, according to the late lord marshal, the experiment had been fairly made on another occasion.

A young Greek lady being brought from her own country to Paris, some years since, was, soon after her arrival in that city, carried to the opera by some French ladies, supposing, as she had never heard cultivated music, that she would be in raptures at it; but, contrary to these expectations, she declared that the singing only reminded her of the hideous howlings of the Calmine Tartars, and as to the machinery, which it was thought would afford her great amusement, she declared her dislike of many parts of it, and was particularly shocked by what she called the impious and wicked imitation of God's thunder. Soon after this experiment she went to Venice, where another trial was made on her unprejudiced ears, at an Italian opera, in which the famous Giazzello fang, at whose performance she was quite disdosed in pleasure, and was ever after passionately fond of Italian music.

PUTAWATAMES, or Pootootamies, in Geography, Indians who inhabit between St. Joseph's and Detroit in North America, and can furnish about 500 warriors. There are two tribes of this name, the one of the river St. Joseph, and the other of Huron. At the treaty of Green ville, August 3d, 1795, they ceded lands to the United States, who paid them a sum of money, and engaged to give them goods to the value of 1000 dollars per annum, for ever.

PUTBUS, a town and fort of the island of Rugen; five miles S. of Bergen.

PUTCABARY, a town of Hindoostan, in Bengal; 45 miles S.E. of Moorshedabad.

PUTEA, in Ancient Geography, a town of Africa propria, S. of Adramietum, between Campa and Caraga, according to Ptolemy. Alfo, a town of Syria, in the Palmere, between Oriza and Abada. Ptol.

PUTEALI, among the Romans, a small kind of edifice raised in the place where a thunder bolt had fallen. See BIDENTAL.

PUTELKAW, in Geography, a town of Prussia, in the province of Ermeland; six miles S.W. of Frawenburg.

PUTEMAHRY, a town of Hindoostan, in Bengal; 16 miles N. of Kichenagur.

PUTEOLANUS PULVIS. See POZZOLANA.

PUTHLOSE, or PUTLOS, in Geography, a town of the duchy of Holstein; four miles N.W. of Oldenburg.

PUTI, or POTTI, a town of the principality of Guriel, at
PUT at the mouth of the Rione, on the Black sea; 80 miles W.S.W. of Cotatis. N. lat. 42°. E. long. 41° 28'.

PUCULI, among the Romans, ditches or holes in the earth, a little without the Equinoctial gate, in which the poorer part of people were buried.

PUTIGNANO, in Geography, a town of Naples, in the province of Baris; 33 miles S.E. of Baris.

PUTIVLID, a town of Russia, in the government of Kurl, on the Sem; 72 miles W.S.W. of Kurl. N. lat. 51° 20'. E. long. 34° 14'.

PUTLACH, a town of Bavaria, in the bishopric of Bamberg; five miles E. of Golfweinfein.

PUTLITZ, or POLTITZ, a town of Brandenburg, in the Mark of Prignitz; 10 miles N. of Perleberg. N. lat. 53° 16'. E. long. 12° 53'.

PUTLEGGS, or PUTLOCKS, in Building, short pieces of timber, about seven feet long, used in building scaffolds.
They lie at right angles to the wall, with one of their ends bearing upon it, and the other upon the ledges or poles which fland parallel to the side of the wall of the building.

PUTNA, in Geography, a town of Moldavia; 32 miles W. of Sucevaz.—Also, a river of Moldavia, which runs into the Middle, at Pocani.

PUTNAM, a county of America, in the southern dis-trict of Georgia, containing 6809 free persons, and 3220 slaves. Its chief town is Eatonton.

PUTNEY, a town of America, in Windham county, and state of Vermont, containing 1697 inhabitants.

Putney, a village and parish in the west half hundred of Brixton, and county of Surrey, England, is situated on the south bank of the river Thames, at the distance of four miles from Hyde Park corner, London. The parish contains 1630 acres, of which the greater proportion is an open common or heath. In the time of the civil wars it was the scene of some very interesting transactions. The parliamentary army lay at Putney, for a considerable time, in the year 1747; and here the general officers, after long debates in the church, completed their propositions for the future government of the kingdom, and sent them to the king at Hampton Court. Here also were born two celebrated statesmen, Nicholas Welt, bishop of Ely, and Thomas Cromwell, earl of Effex, the protegé of Wolsey, and the successor to his power and misfortunes. In this parish are many agreeable villas; in one of which the late illustrious William Pitt breathed his last. The church was originally built as a chapel of ease to Westminster, not long after the conquest; but was, in a great measure, re-erected in the reign of Henry VIII. It is a small edifice, with a steeple tower at the east end. A little chapel at the eastern extremity of the south aisle, built by bishop Welt, is, however, its chief ornament. Monuments and inscriptions are numerous, but few of them deserve notice. Over the Thames, in this parish, is a wooden bridge, constructed in the year 1729, at the expense of £3,973; and yielding a revenue, by tolls, to the proprietors, of above 5000l. per annum. A fishery here was poached by the lord of the manor, previous to the conquest; and is now rented for a considerable sum. All litigious and porcupines are claimed by the lord mayor of London, but the fishermen receive 13. for each of the former, and a guinea for each of the latter, when delivered to the water bailiff. On the common stands an obelisk erected in 1736, in memory of Hartley's invention for fencing building against fire.

PUTNOK, a town of Hungary; 36 miles W.N.W. of Tokay.

PUTORIUS, in Zoology, the Pole-cat, a species of Mustela; which see. See also Pole-cat.

PUTORIUS Serpius, a name given by some to that species of serpent called by others dryinus.

PUTREFACTION, or Putrification, in Chemistry, is a species of fermentation (which see); being the last stage of the fermentatory processes, and agglutinating not merely in the decomposition and transposition of the particles of putrifying substancess, whether animal or vegetable, by which new combinations are produced, but also in the extrication and expulsion of some of the constituent parts of these substancess.

This decomposition or derangement of the constituent parts of vegetable substancess is usually called fermentation, and that of animal bodies, is denominated putrefaction. The agents that produce both kinds of decomposition, and the circumstances that attend them are, in various respects, very similar, and the chief difference of the products that are obtained from both depends upon the diversity of their constituent parts. The process of putrefaction, and its effect in dissolving the combination of the constituent parts of bodies, are sufficiently obvious to fene; but the rationale of the process, and the mode in which gaseous and volatile compounds are separated from bodies that are disorganized and afterwards form new combinations, are still involved in considerable obscurity; and different writers have disagreed in their exposition of them. Several facts, however, are universally acknowledged; and of these we shall give a brief account in the sequel of this article, together with a detail of some of these principles and theories that have been adopted for explaining them. Becher long ago observed, in his "Phy. Subl. l. i. § 5." that air is the principal agent of decomposition, but that water and heat very much facilitate its action. Thus he says, "Fermen-
tatio ergo definitur quid facit corporis denifioris rarefactio, particularumque aérearum interpositio; ex quo conclusio debetur in aere fieri nec minus frigidum, nec rarefactio impedientur; nec minus calidum, nec partes raribiles expellantur."

An animal substancess may be preferred from putrefaction by depriving it of the contact of the air; and this process may be accelerated or retarded by varying or modifying the purity of the same fluid. When we observe putrefaction occurring without the access of atmospheric air, the effect is produced by the water which impregnates the animal substancess, becomes decomposed, and affords the element and the agent of putrefaction. Hence it appears, that moisture is an indispensable requisite to facilitate putrefaction. A moderate degree of heat is also a condition favourable to animal decomposition.

Dr. Hales, it is well known, ascribed the cohesion and solidity of bodies to the air, which exerts in them in a fixed state, and forms, as he expresses it, the cement or bond of union between their several constituent particles. To this purpose he observes, that air abounds much more in solid than in liquid bodies; and that solid bodies being generally denser than water, the attraction of the air of these solid bodies in a fixed state, and its repulsion when in a clastic state, are greater than the attraction and repulsion of the lighter watery particles in a fixed and in an clastic state; and hence the particles of air are fitter to be the principal bond of union in solid bodies, than the particles of water. This opinion was afterwards adopted by baron de Haller, who maintains, that air is the vinculum elementarum primam, or the true cement which binds together the earthy particles
PUTREFACTION.

particles of bodies. Mr. Macbride, as we have elsewhere shewn, has taken occasion, by a variety of experiments, to illustrate and establish this opinion; and in support of it he alleges, that the preservation of firmness and soundness in bodies depends on restraining the escape of that principle, since known by the name of fixed air, and which he supposes to be the immediate cause of cohesion: for the moment it flies off and refurnes its affinity, the other constituent particles, viz. the earthy, the saline, the oily or inflammable, and the aqueous, being thereby put in motion, immediately begin to exert their several peculiar attractive and repulsive powers, and run into new combinations, which first change, and at length altogether destroy the texture of the substance they formerly composed; provided that this substance contained in itself a sufficient quantity of water to allow of the intelline motion, by giving the proper degree of fluidity; for without fluidity there can be no intelline motion; and without intelline motion there can be no change of combination: because we fee that fuch animal and vegetable bodies as are suddenly deprived of their water, or nearly; contain very little, are almost as durable and unchangeable in their texture as minerals. Hence Acofta observes, that in Peru, and others have observed the fame in Egypt, where it very rarely rains, every thing will continue a long time uncorrected; unless we should rather acribe this effect to the abundance of nitrous falt in the air of thofe places, which is known to refit putrefaction. Indeed all putrefactions, both of animal and vegetable bodies, are acribed by the learned Boerhaave to be performed by means of water alone. Take, fays he, a pound of fresh flesh, and keep it in a heat like that of our body, and, in a few days the putrefaction will be completed; but if you fift drain out, or exhale, all the watery part from the fame in fome chemical vefsel, though the falt and oil remain, the flesh will harden like a ftone, and may be kept for ages without putrefaction. Though when thus hardened, water poured on it, or even the common dew, will soon fet it a putrefying. Thus Villarlis and Caazalet of Bourdeaux, as Chap- tal informs us, dried meat by means of fieves, which was preferved for feveral years without contrafting any bad flavour.

By fuch means, bread, flesh, or the like foods, may be preferved for many ages; provided regard be had to the place. Hence it is, that in dry countries, as Egypt, dead carafes never putrefy, but dry and harden uncorrected: as we fee also in the mummies found buried under the fand.

The lands and light porous earths prefere human bodies by exhaufting their juices and drying the solid parts. Hence it is, that entire carafes have been discovered in Arabia, confifting of men and camels, preferved in the lands under which the impetuous winds have buried them. In the library of Trinity college, Cambridge, a human body may be feen in a perfect flate, which was found under the fand in the ifland of Teneriffe. Hence putrefactions prefure much more slowly when exposed to a drying wind, than in a feltered place.

Nevertheless, too much humidity impedes putrefaction. To this purpofe Becher obferves: "Ninia quoque humiditas a putrefactione impedit, prout nimius calor; nam corpora in aqua potius gradatim confunti quam patuterecre, fi nova tempesta more integra interdum submerfa profurus a putrefactione immundi vidimus; adeo ut nobis aliquando speculatio occurreret, trahendo tali modo cadaver anatomicus subjicienda, quo diutius a ferto et putrefactione immundi foret." Accordingly it is neccessary, that in order to a body's putrefaying by moifture, that the water fhould impregnate but not inundate it. It is alfo neceffary, that it fhould remain in the texture of the animal body, without being re- moved; for thus the lymph is dissolved, and the molt putrefacible substance is prefented to the air with the greatest extent of surface; and the water itself is decomposed, and by this means affords the putrefacible principle.

Even human blood, which, naturally, is fo prone to putrefaction, if you deprive it of its watery part, may be kept for fifty years. Goat's blood, we actually find kept fo long in the fheps, without corrupting; though, if you diflove it in water, and expose it to a gentle warmth, it will putrefy immediately. Blood is faid to be the molt putrefacient animal putrescence that is known; and this property is afcribed partly to its fluidity and partly to the large quantity of fibrin and uncondenfed albumen, which it contains, and efpecially to the former. See Blood.

We fhall here add, that animal fubstances fhow to be (ceteris paribus) more putrefacient in proportion to the number of confluent parts which they contain. The fubstances either absolutely or nearly indecompofterable, are bone and condenfed albumen, the latter being fuch as exits in cuticles, nails, hair, &c. which long remain unmufed in the midft of putrefyng fubstances. Animal oil also putrefyes with great difficulty, and hence the people that live in the molt northern parts of America, the Esquimaux and others, preferve fish and meat to a certain degree from putrefaction by immersion in fift-oif.

In putrefaction there is a great intelline motion, which, when carried to an extreme, and when the putrefying fub- stance is much comprifed, is accompanied with heat and fmoke, and frequently flame. However, M. Beauap affirms, that putrefaction is not attended with any fenfible heat: when, indeed, it proceeds slowly, and the quantity of putrefying matter is but small, the heat, if any, is very little. That putrefacient fubstances emit light, is an unequivocal fct; and on this principle philofophers account for the luminousnefs of the feta, the ignis fatus, &c. To this purpofe M. Ant. Martin (Swed. Abh. vol. xxiii. p. 225, cit. by Dr. Priestley, in his History of Light, &c. p. 576.) obferves, that human bodies have fometimes emitted light about the time they begin to putrefy; and that the walls and roof of a place in which dead bodies had often been exposed, had a kind of dew or clamminefs upon them, which was fometimes luminous. And he imagines, that the lights which are faid to be feen in burying grounds may be owing to this caufe. It has been obferved, that heat extinguifhes the light of putrefcant fub- fances; Mr. Canton, attending to this circumstance in fome experiments for afcertaining the caufe of the luminousnefs of the feta, remarks, that though the greateft fummer-heat is well known to promote putrefactions, yet twenty degrees more than that of the human body cannot hinder it; for putting a small piece of luminous fih into a thin glafs ball, he found that water of the heat of one hundred and eighteen degrees would extinguifh its light in lefs than half a minute; but that on taking it out of the water, it would begin to recover its light in about ten fecfonds: but it was never afterwards fo bright as before. See Light.

It has been obferved, that a temperature from about forty degrees to the highest natural heat is favourable to the putrefaction of animal matter, whereas a freezing tempera- ture is known to flop putrefaction, as it is the custom in cold countries to bring victuals frozen to market, and in this flate they are kept for any length of time without any other preparation; and besides, bodies of men or of other animals remain unaltered under ice for many weeks. We might
might allude many other circumstances of a similar nature.
On the other hand, a scorching heat also prevents putrefa-
*ction; probably by expelling the moisture which is essen-
tial to the process, because by an inferior degree of heat
putrefaction is promoted. The influence of temperature
on animal putrefaction is thus stated by Becher: "Aer calidus
et humidus maxime et putrefactionem facit—corpora
frigida et fissa difficultur, imo aliqua profusio non putrefunct;
quae ab imperitis proinde pro factis habetae fuerit; ita aer
frigidus et ficus, imprimit calidus et ficus, a putrefac-
tione quoque prevarit; quod in Hispania videmus, et locis
albis calidis, ficco, calido aere præstitis, ubi corpora non
putrefuent et refolventur; nam cadavera in oriente in
arena, imo apud nos arte in furnis, tecari, et sic ad finem
mundi utque a putredine prevarari, certum est: intentione
quoeque frigus a putredine prevarare; unde corpora Stock-
holmiae tota hyeme in patibulo fulpffet fine putredine
animaldormitum." From the facts already stated, we may de-
duce the most effectual means of preventing, and increasing
putrefaction, and also of modifying it at pleasure. A body
may be preserved from this process, by depriving it of any
contact of atmospheric air; for this purpose nothing
more is required than to place the body in a vacuum, or to
envelope it in a covering, which may defend it from the
immediate action of air; or else to envelope it in an at-
mophere of some gaseous substance, which does not con-
tain vital air. Putrefaction may also be favoured by keep-
ing bodies at a suitable temperature. A degree of heat
from between sixty-five and ninety degrees diminishes the
adhesion of the parts, and favours the action of the air;
but if the heat be greater, says Chaptal, it volatilizes the
aerose principle, dries the solids, and retards the putrefa-
tion. Hence it is inferred, that for the decomposition of
an animal sub stance, it is necessary that it should have the
contact of atmospheric air, and that the purer the air is,
the more speedy will be the putrefaction: that it be exposed
to a moderate degree of heat; and that its texture be im-
pregnated with humidity.
The most sudden and remarkable changes produced upon
a body by putrefaction, are upon its colour, smell, and taste.
Flesh beginning to putrefy, is well known to exude very
soon after a penetrating fetid smell, its colour becomes pale,
then inclining to blue, and afterwards livid and black, and
its taste nauseous. Transparent liquor, as urine and broth,
during putrefaction, becomes also turbid: as the putrefac-
tion advances, the smell becomes more and more fetid, and
it also acquires great pungency, which is caused by a large
quantity of volatile alkali, dilugaged from those substan-
tes that are completely putrefied. Solid bodies, whilst
they are putrefying, twelLc, become soft, lose the cohesion of
their parts, and are lastly reduced to a very disagreeable putrid
pulp maws: the fluids become turbid, and the effluvias are
loathsome and sickening, and after a time a putrid gas is
dilugaged in a slow but sensible effervescence. A foul and
brown ferment then sweats out from the pulp maws, and
about this time the effluvium is very febly ammoniacal,
which is indicated by its effects on the eyes and throat, and
by forming a white vapour with muriatic acid gas. For
some time a large part of the putrid substance is evapo-
rated, and carried off in the putrid gas and dispersed in the
atmosphere, after which the extreme factor fumes, and
finally the process of putrefaction ceases, and leaves a kind
of fat fetid carby matter. All the gases certainly known
to be produced by putrefaction, are carbonic acid, carbu-
retted hydrogen, fulphuretted and phosphuretted hydrogen,
and ammonia; but either these, or some of these, must be
considerably changed by the solution of the animal matter;
or some compound not yet examined, must be produced in
that state of putrefaction, when the gas evol ved occasions
such dreadful effects upon those that have the misfortune
to fall in the way of it, even when diluted considerably with
common air. This is said to be the case when the abdomen
of a large animal is first burst, after some days or perhaps
weeks of putrefaction; the gas from which causes instant
fainting, and sometimes death, and even when the person
exposed to it receives the first shock, it leaves excessive de-
bility and other alarming symptoms for a considerable time.
The most deleterious gas that is known is, perhaps, car-
buretted hydrogen, but the effects of this, as obtained by
chemical means, are far short of those above-mentioned,
when equally diluted. The generation of ammonia has been
satisfactorily accounted for, since the discovery of the con-
stituent parts of the volatile alkali, by the new combination
formed between the azote of the animal matter, and the
hydrogen, of which latter there are many sources, and par-
icularly that of the decomposition of water. As ammonia
is always produced during putrefaction, it seems rational to
suppose, that one important purpose of the moisture neces-
sary to the process, is to afford, by its decomposition, the
hydrogen of the volatile alkali. The nitrous acid is also an
undoubted product of putrefaction; but farther experiments
and facts are necessary for explaining the reason, why in
some cases the azote tends to unite with oxygen to form this
acid, and in others with hydrogen to form ammonia. For
an account of the peculiar changes which animal flesh under-
goes, by which it is converted into a fpermaceti-like sub-
fstance, instead of passing through the usual process of putrid
decomposition, we refer to the article ANIMOCHE.
to the thirty-fifth, twenty-fifth, and tenth degrees of heat, indicated by Reaumur's thermometer, and at the end of twenty-four hours mixed them with acids; and he found, that the bile which had been placed in a degree of heat answering to thirty-five, was most dilated, and gave very slight indications of effervescence; which that had stood in twenty-five was also dilated, and the acid produced a more sensible effervescence, but still very slight; and the bile which had been exposed only to the temperatmn of the air, varying from seven to ten, preferred its tenacity, and fermented as much as that in his first experiment. Having mixed some blood, taken out of a vein of the dead body at the same time, and which appeared to be of the yellowish-red, with spirit of nitre, the mixture effervesced, but in a much less degree than the bile: this mixture, being left to digest for some hours, a yellow ferment separated from the blood, and covered its whole surface; and the blood, being subjected to the same heat as the bile, and for the same time, appeared more disposed to effervescence than the bile, though this disposition afterwards gradually diminished. From these experiments the ingenious writer infers, that in diseased bodies the humours may become alkali as to effervescence with acids: that a very high degree of putrefaction and fcor, which is not sufficient to produce alkali out of the body, will produce it in the body; that alkali formed in the body, and contained in the bile, is extremely volatile, since the heat of twenty-five degrees made a great part of it evaporate; and that the alkali alkali contained in the blood, being a little more entangled with other elements, is consequently less volatile, since the same degree of heat continued for the same time, dilated but a very inconsiderable part of it: and, therefore, that the different phenomena taken notice of by those who have prosecuted experiments of this kind, some of whom affirm that they have seen undoubted proofs of the presence of an alkali, and others that they have scarcely discovered any such indications at all, are the effects of different degrees of heat, the idleness of the substance exposed to the heat, or the different volatility of the alkali arising from its cohesion with other principles. Having made similar experiments upon healthy bile, blood, and serum, and submitted them to the action of mineral acids, he found the bile most disposed to effervescence; that human bile was more disposed to effervescence than the bile of an ox; that corrupt blood ferments with acids still slower; and that serum ferments slower than blood. He also observed, that putrefacient humours not only effervesced with mineral acids, but with very weak distilled vinegar; and that those humours that have been exposed to artificial heat, become fcorid and effervescence soon, and fooneat arrive at the habit of fermentation; in which case the fermentation ceases, though the heat is continued; and the smell, which till then is intolerably fcorid, becomes herbaceous, and is not disagreeable. The fcorid, he says, manifesf itself sooner and lasts longer than the alkali.

M. Gabor farther observes, in relation to the experiments of Sir John Pringle, that in the degree of heat to which he exposed putrefacient substances, and which was equal to the hundredth degree of Fahrenheit, corresponding nearly to the thirtieth degree of Reaumur, animal humours very soon become putrid; but that they as soon lose the alkali which they derive from putrefaction, if this degree of heat is continued; so that as the corrupting humours manifesf their alkali as quality only for a very short time, it might easily happen that no sign of alkali appeared in his experiment, if it was not made in the critical moment, i.e. if he examined the putrefacient humours a little before the alkali was formed, or a little after it had evaporated. And he, therefore, apprehends, that if Sir John Pringle's experiments were made with a degree of heat just equal to his own, the result, ceteris paribus, must have been the same.

From other experiments this writer infers, that blood received from the arm, agitated and left to putrefy, does not putrefy so soon, nor so soon manifest signs of effervescence, as the red part separated from the serum, because the serum putrefies more slowly than any other animal humour; and that the alkali, which evaporates with a degree of heat from twenty-five to twenty-eight of Reaumur, being collected in a receiver, will effervesc, and that the residuum is a mafs extremely fcorid, wholly diftillate of alkali, and, consequently, that no effervescence is to be expected by pouring acids upon it. Having kept some blood in a glass vessel close stopped, he found that it retained its alkali as a long time, though exposed to a degree of heat equal to twenty-five; but upon unstoping the vessel, it flew off with great violence, in an extremely fcorid vapour. These explications he attributes to the expansion of the air, in consequence of the putrefaction; and hence he deduces the reason, why the humours that are contained in the vessels of a human body become alkali while they are yet scarcely fcorid, although when drawn from the body, and kept in open vessels, they become fcorid, before they give signs of alkali. As soon as they begin to form alkali in the vessels, the alkali is retained; but as it exhalas from vessels exposed to the air, a greater quantity must be formed than exalas before it can become fcorid. Having collected the diluted liquor of blood in such a flate of putrefaction as to effervescence with acids, and exposed it to the action of various acids, a violent effervescence ensued; and when poured upon syrup of violets, it produced as fine a green as sprits of hartshorn; and this tincture, having been changed into a red by the effusion of a few drops of aqua fortis, became again blue, upon pouring into it some more of the diluted liquor; whence he concludes, that putrefacient humours form a true alkali, which exalas with a very fcorid heat. From other experiments he infers, that the alkali of putrefacient substances is not the producive caufe of their fcorid, because the latter remains when the former is departed. But as both appear in the same degree of heat, when long continued, it appears, he says, that this factor is produced by the effusion of parts extremely volatile, but different from volatile alkali, which, though sooner produced, are more slowly diffipated. Alkali, however, may be sometimes connected with a flight factor; and, on the contrary, extreme factor may sufff without alkali. And this fact confirms the observation of Sir John Pringle, who found a difference between the fcorid and alkaline particles; since the exhalas of fresh urine are not pernicious, though they contain more alkali than any substance in a flate of putrefaction, the odour of which is pernicious in the highest degree; and, therefore, putrid effusion are of a different nature from alkali farts. M. Gabor farther adds, by way of inference from this fact, that a volatile alkali is not a necessary product of putrefaction, and that the degree of alkali is not equal to that of putrefaction. Dr. Croll, professor of Chemistry at Brunswick, has objected to this doctrine, as not conformable to the phenomena (Phil. Trans. vol. Lxi. part i. art. 39.) for he supposes, that as all femel depends on a stable matter joined with phlogiston, and the stable matter producing the putrid fclush was very probably not an acid, it must be a volatile alkali, which, involved in phlogistic matter, might fly off before the alkali was developed. From some experiments made with a view of ascertaining this fact, he infers that the volatile alkali is present as long, at least, as the putrid femel continues, and that this volatile alkali is the basis of it; because, as this was
PUTREFACTION.

distilled over in his experiments, the residue, being still in
intelline motion, required only the herbaceous smell. The
reason why the volatile alkali has been distinctly observed at
a certain period of putrefaction, and not in the other, he
apprehends to be this: the volatile alkali has, it seems, a
tendency to difentangle itself, by intelline motion, of all
such matter as it is involved with; but if it is not combined
with such fixed matter as retains it till has gone through all
its evolutions, it is, being itself volatile, carried off by the
still more volatile phlogistic matter with which it is commonly
joined. For this reason, he supposes the putrefying matter
flows in its beginning no signs of volatile alkali, because its
smell depends only on those particles which have been on the
surface, without any strong cohesion with the substance.
In the farther progress of putrefaction, the matter involves
the alkali, or forming it, is internized, and in cohesion with
the solid particles of the substance, and is by these means
retained till the alkali is come to its purer state. Towards
the end of putrefaction, the cohesion of the particles being
almost entirely taken off, the volatile alkali is carried off before
it can go through all its states.

Dr. Macbride made several experiments with putrid blood
and putrid bile, which ascertain the fact, that as soon as an
animal substance begins to putrefy, it begins to discover an
alkaline quality; and this volatile matter, now produced in it,
may be separated by distillation in a very gentle warmth;
but he observes, that the volatile alkali obtained from put-
rid substances is not exactly similar to that obtained by
violent heat from animal substances not putrid. It differs
remarkably in the flavour, which is nauseous and disagreeable,
is not so pungent, and is much weaker than the common
volatile alkali; and this latter is capable of dissolving
the putrid alkali, and of driving it off from any body to which
it has been united. But to return from this digression. As
to the cause and process of putrefaction, it has been generally
believed, that the contact of atmospheric air is necessary
for this purpose, and that bodies become putrid, because air
communicates somewhat to them: accordingly it has been
alleged, that bodies buried deep under the earth, or in
water, out of the reach of any air, have remained entire for
ages; which, when exposed to the open air, have soon
rotted and mouldered away. It is also well known, that
bodies are preserved from putrefaction by covering them with
wax, seet, &c.; and Mr. Boyle relates, that he has preserved
lemons, oranges, and other fruits, from putrefaction, during
several years, by including them in an exhausted receiver.
Experiments of the same kind have been lately made by
M. Eller of Berlin, which shew that substances, even of
the most putrefacnt nature (such as blood) may be kept
found in vacuo for many years. But Dr. Macbride has
urged a variety of facts and considerations to prove, that
putrefaction enties in consequence of the loss of prime
principle, which cemented the component particles of bodies,
and that, when this is disengaged from them, they separate,
and are diffundt. This principle he discovered to be air,
which, in putrefaction and fermentation, is extricated and
thrown off, from a fixed and non-elastic state, into one that
is volatile and elastic; but which immediately, upon meeting
with a proper recipient, returns again to its former nature.
Thus he found, that caustic alkali and quicklime may be
rendered mild by absorbing this air, extricated from put-
refying and fermenting substances; that without the extrication
of this air, putrefaction cannot happen; and that even by ab-
sorption of it, putrefied substances may be corrected and
rendered sweet. To the same purpose Dr. Alexander has
endeavoured to prove, that putrid matter will preserve other
substances from putrefaction; which is not improbable, be-
cause, being already satured with the putrid effluvium,
they cannot readily take any more. Dr. Macbride, having
exposed putrid matter to the vapours arising from ferment-
ing mixtures, or from alkaline substances eliuring with
acids, found that the putrid quality was destroyed; and
hence he concludes the fixed air as powerfully antiseptic.
And it appears also from the experiments of Dr. Priestley,
that fixed air corrects and renders wholefome air tainted with
respiration or putrefaction. Hence he infers, that lime-kilns,
which discharge great quantities of this air, may be wholefome
in the neighbourhood of populous towns, the atmosphere of
which must abound with putrid effluvium. Sir William Lee, in
a hot reafon, contrived, by impregnating water with fixed air,
in the manner described under Pyrmont water, and with
putrefied meat, for two or three times a-day, not only to prejudice
it as perfectly fresh and good to the extent of ten days, as
at the first killing, but also to recover some meat that had
begun to change. And it is farther well known, that fixed
air, or carbonic acid, has been lately introduced into the materia
medica, and administered with success in a variety of putrid
cases. Dr. Macbride has also proved, that putrefaction is
accelerated by taking off the preffure of the atmosphere,
and from some experiments he was led to conclude, that it will
take place sooner in vacuo than in the open air; but making
a more complete vacuum by means of two brafs hemispheres
joined together, he found that the observation of Mr. Boyle
and others was agreeable to fact. It appeared also, by inclu-
sing feth in condensed air, that increasing the preffure of the
surrounding air, retarded putrefaction; and hence he
deduces, what he deems to be a demonstrative proof, that
bodies do not putrefy, because the air adds somewhat to
them; for if they did, then a piece of flesh which lay in
condensed air ought to have putrefied the sooner, because it
had the greatest quantity of air applied to its surface. But
the reason why, according to his system, condensed air pre-
vents putrefaction, is, that the preffure of every side must force
the constituent particles closer together, thus increase their
cohesion, and prevent the intelline motion; and without
intelline motion there can be no change of combination.

However, it is observed by Sir John Pringle, that the put-
refaction of meat and other substances, advances quicker in a
condensed air than in free air; for as the most putrid parts are also
the most fugitive, they incessantly issue from a corruptible
substance, and disperse with the wind; but in a stagnation
of air they remain about the body, and in the nature of a
ferment excite its corruption.

It has been long observed, that putrefaction generates air.
Hence, though feth, as well as blood, be specifically heavier
than water, yet dead bodies are found to float, after
lying some time at the bottom, from air generated in the
bowels by putrefaction. And since it has been found by
experiments, that the blood and other animal substances
begin to emit air before they are so far corrupted, as they
frequently are in putrid diseases, it is probable that
the fymptoms in deep surfeits may be owing to the action
of the confined air. As dead bodies become putrid from
the loss of their fixed air, according to Dr. Macbride's
theory, he fuggels, that the immediate cause of putrefaction
in living bodies may be the detachment of too large a propor-
tion of their fixed air. This fact is strongly supported by an
enumeration of the symptoms that occur in the feverity,
and other highly putrid diseases, which shew that the air
is actually detached from the blood in such cafes; as well
as from an examination of the principal and prevailing caufes
of such disorders. And since the air tainted with animal or
vegetable putrefaction is the fame with air rendered noxious
by animal respiration; since both equally extinguih flame,
are equally noxious to animals, are equally and in the same way offensive to the smell, equally precipitate lime in lime water, and are restored by the same means, Dr. Priestley suggests; that one use of the lungs is to carry off the putrid effluvia, without which, perhaps, a living body might putrefy as soon as a dead one. See Blood and Respiration.

We shall here observe, that putrefying and fermenting substances have been found, by the experiments of Mr. Cavendish, Dr. Priestley, &c. to yield not only fixed but inflammable air. From an experiment of Dr. Priestley, intended to determine the proportion of each of the kinds of air in the different stages of the putrefactive processes, it appears that a piece of mutton weighing four pounds weighs six grains, yielded in all 2544 volumes of air, of which 2500 was fixed, and the rest inflammable; and that all the inflammable part was exhausted a considerable time before the fixed air. The fame ingenious writer has observed, that the diminution of common air, by means of putrefaction, amounts to a complete fourth part of the whole, notwithstanding the production of some permanent air from the putrefying substance, and has, in all respects, the appearance of being produced solely by the precipitation of fixed air. It must occur to every reader, in any way acquainted with this subject, if the pugilistic theory be admitted, (which indeed is now generally discarded,) that if inflammable air be the same with phlogiston, as Dr. Priestley seemed to have discovered, many of the phenomena of putrefaction, depending on this principle, such as the smell, colour, light, &c. will probably from hence admit of an easy explanation.

We shall here subjoin some observations with respect to the decomposition of animal bodies that are interred in burying-grounds. In this situation, the decomposition is four times as fast as when the putrefying animal is exposed to the air. It is not perfectly ended, according to Mr. Petit, till three years after the body has been interred, at the depth of four feet; and it is slower in proportion as the body is buried at a greater depth. These facts agree with the principles which we have already established for bodies buried in the earth, and subjected to laws of decomposition very different from those which take place in bodies exposed to the open air. In this case, the decomposition is favoured by the waters which filter through the earth, and diffuse and carry with them the animal juices. It is also favoured by the earth, which absorbs the juices with more or less facility. Mefirs. Lemery, Geoffroy, and Hunaud, have proved that argillaceous earths exert a very slow action upon bodies; but when the earths are porous and light, the bodies then dry very speedily. The several principles of bodies absorbed by the earth, or carried by the vapours, are diffused through a great space, imbied by the roots of vegetables, and gradually decomposed. This is what passeth in burying-grounds in the open air; but it is very far from being applicable to the foulures which are made in churches and covered places. Here is neither water nor vegetation; and consequently no cause which can carry away, dissolve, or change the nature of the animal fluids: and we cannot but applaud the wisdom of government, which has prohibited the burying in churches; a practice which was once a subject of horror and infection.

The accidents which have happened at the opening of graves and vaults are but too numerous, to render any apology necessary for our fpaking a few words respecting the method of preventing them. The decomposition of a body in the bowels of the earth can never be dangerous, provided it be buried at a sufficient depth, and that the grave be not opened before its entire and complete decomposition. The depth of the grave ought to be such that the external air cannot penetrate it; that the juices, with which the earth is impregnated, may be conveyed to its surface; and that the exhalations, vapours, or gases, which are developed or formed by decomposition, should not be capable of forcing the earthy covering which detains them. The nature of the earth in which the grave is dug, influences all its effects. If the stratum which covers the body be argillaceous, the depth of the grave may be less, as this earth difficulty affords a passage to gas and vapour; but in general it is admitted to be necessary that bodies should be buried at the depth of five feet, to prevent all these unhappy accidents. It is likewise necessary to attend to the circumstances, that a grave ought not to be opened before the complete decomposition of the body. This decomposition, according to Mr. Petit, is not perfect until the expiration of three years, in graves of four feet depth; or four years, when they are six feet deep. This term affords many varieties, according to the nature of the earth, and the constitution of the subjects buried in it; but we may consider it as a medium. The pernicious custom, which allows a single grave to families more or less numerous, ought therefore to be suppressed; for in this case, the fame grave may be opened before the time prescribed. These are abuses which ought to occupy the attention of government; and it is time that the vanity of individuals should be sacrificed to the public safety. It is likewise necessary to prohibit burying in vaults, and even in coffins. In the first case, the principles of the bodies are spread into the air, and infect it; in the second, their decomposition is slower and less perfect.

If these precautions be neglected; if the dead bodies be heaped together in too confined a space; if the earth be not proper to absorb the juices, and decompose them; if the grave be opened before the entire decomposition of the body;—unhappy accidents will no doubt be produced; and these accidents are but too common in great towns, where every wise precaution is neglected. An instance of this happened, when the ground of the church of St. Benoit at Paris was dug up a few years ago: a nauseous vapour was emitted, and several of the neighbours were affected by it. The earth which was taken out of this grave was putrid, virous, and emitted an infectious smell. Mefirs. Maret and Nevier have left us several familiar observations. Chaptal's Elem. of Chem. vol. iii.

Putrefaction is one of the instruments in nature by which many great changes are brought about. In the processes of vegetable putrefaction, if we throw together any of the tender, green, and succulent parts of recent vegetables, whether acid or alkaline, in a large heap, in the warm open air, and press them down with an additional weight, if their own be insufficient; the middle part of the heap will, in a little time, spontaneously conceive a small degree of heat, and pass successively through the other degrees, till it arrive at a state of ebullition, and be perfectly putrefied.

In the space of three days, from the first putting them together, they will yield a heat, perceivable by the hand, equal to that of a human body in a healthy state; by the fifth, the heat will be too great for the hand to bear without pain; and, lastly, by the sixth, seventh, or eighth day, the juices will generally appear ready to boil; and sometimes the matter will even flame, and burn away.

By this spontaneous operation, the vegetable acquires an abominably putrid, fוכרaceous, or cadaverous, taffte, and odour; and turns entirely into one soft, fimilar, pulpuy mass, or cragimentum, greatly resembling festid human excrements in the faeces, and putrefied flesh in the table.
PUTREFACIATION.

If now this fetid matter, thus obtained, be directly, whileit it remains in its fetid state, committed to a glass retort, and distilled with proper degrees of fire, there will come over, 1. A water impregnated with an urinous spirit, perfectly like that obtainable from animal subjeets, and separable by a fresh distillation slowly made in a tall glass, into elementary water, and a large quantity of pure, white, volatile, dry, alkaline falt, not to be distinguished from animal fats. 2. A volatile, alkaline, oily falt, that fhoots into globes. 3. An exceedingly volatile and thick fetid oil, both which are entirely like thofe of animals. And, faftly, the remainder, being calcined in an open fire, affords not the leaft particle of fixed falt; but as if the subjed had really been of the animal, and not of the vegetable kingdom.

This proeed is truly universal, and holds equally in all kinds of vegetables, though ever fo different in their nature and virtue.

Experiments have been made in the coldeft and moft fucceulent, or water, plants; fuch as purflane, forrel, &c. as well as with the hoottet or mall aromatic, fuch as the fpurges, &c. and it was always found to succeed; but that the fooner, as the vegetable employed contained the greater quantity of oil; though with the fame phenomena.

It will likewise succeed with dry vegetables, provided they be moistened with water before they are thrown into heaps; and thus we fet at once, that facks of hay will spontaneously take fire, and burn away; especially if the hay was not well dried in the making.

The conditions neceffary for the putrefacion of vegetables are similar to thofe required in the putrefacion of animal fubfances. It is neceffary that the organization be impregnated with water; the contact of air is neceffary, as is alfo a certain degree of heat; and for the due effect of this kind of decomposition, the vegetables should be heaped together, and their juices be abundant. In these circum-]stances, the phenomena of decomposition are as foow: the colour of the vegetable is changed; the green leaves become yellow, the texture becomes lax, and the parts lefs coherent; the colour of the vegetable itself changes to black or brown; the leaves rife, and perceptibly swells up; the heat becomes more intenfe, and is perceived on approaching the heap; and the fumes which arise have already a fhmal, which fometimes is not difagreeable; at the fame time bubbles arise, and break at the furface of the liquid, when the vegetables are reduced to a magma. This gas is a mixture of nitrogen, hydrogene, and carbonic acid. At this epocha, likewife, an ammoniacal gas is emitted, which is formed in feme circumstances; and, in proportion as thefe appearances diminish, the strong and offensive odour is fuc-ceeded by another which is fainter and milder, and the mafs becomes dry. The internal part still exhibits the vegetable structure, when the ftem is solid, and the fibrous matter has been the predominating principle; and it then conftitutes manure or foil. Hence it arifes that the herbaceous plants of a leafe texture, and abounding in juices, are not capable of forming manure by their decomposition, but are reduced into a brown mafs of little confidenfe, in which neither fibre nor texture are obferved; and this is what, for the moft part, forms vegetable mould.

Vegetable mould usually conftitutes the first covering or stratum of our globe; and in fuch cafes wherein it is dif-covered at a depth in the earth, there is no doubt but it has been buried by fome revolution.

When a vegetable is converted into earth by this tu-mulent fermentation, it still retains the remains of the vegetable, mixed and confounded with the other folid earths and metallic产物s; and by dilillation it affords oil, ni-trogene gas, and often hydrogene. It may, therefore, be confidered as an intermediate fubfance between crude and organic bodies, which participates of the inertia of the one, and the activity of the other; and which in this flate is full fubjeet to an infensible fermentation, that changes its nature ftil more, and deprives it of all its organic contents. Thele remains of vegetables, full contained in vegetable earth, ferve as food for other plants that may grow in it. The infensible progress of fermentation, and the fucion of vege-tables, impoverish the vegetable earth, deprive it of all its organic matter, and there remain only the earths and meta-"
PUTREFACTION.

It is, therefore, justly observed by lord Bacon (Nat. Hist. cent. iv.) that an enquiry into the means of preventing or staying putrefaction is of excellent use in phyletic. Sir John Pringle has made many curious experiments with a view of determining the power of certain substances to promote or to prevent putrefaction, together with remarks on this subject, which are published in the Phil. Trans. vol. xlvii. p. 480.

255, 550, and by way of appendix to his Observations on the Diseases of the Army. From the experiments of this learned and judicious physician, it appears, that salts of every kind, whether acid, alkaline, neutral, fixed or volatile, as well as the astringent and gummy-resinous part of vegetables, all of them refit and most of them correct putrefaction; and he purified this branch of enquiry so far as to enable him to form a table showing the comparative antiseptic power of the several substances, that of sea-felt being the standard. See this table under the article Antiseptic.

Of all acrid substances, he found that camphor refited putrefaction most powerfully; its antiseptic power being three hundred times greater than that of sea-felt. Decoctions of wheat, barley, and other farinaceous grains, checked putrefaction, by becoming four. He also made experiments to discover the effects of mixing vegetable with animal matters.

Two drams of raw beef, as much bread, and an ounce of water, being heat to the consistence of paste, and exposed to 50° of heat, according to Fahrenheit’s thermometer, began to ferment in a few hours, and continued in a fermentation two days. When it began to ferment and swell, the putrefaction began; and in a few hours afterwards the smell was offensive. Next day the purrid smell ceased, and an acid taste and smell succeeded. Fresh alimentary vegetables, as spinach, asparagus, turnips, and other similar plants, were put into the mixture, and the whole produced effects as bad on flesh, but in a weaker degree. From several other experiments, he found that animal substances excite the fermentation of vegetable substances; and that the latter substances correct the putrefaction of the former.

By adding salvia to a similar mixture of flesh, bread, and water, the fermentation was retarded, moderated, but rendered of twice the usual duration, and the acid produced at last was weaker than when no salvia was used.

By adding an oily substance to the common mixture of flesh, bread, and water, a stronger fermentation was produced, which could not be moderated by the quantity of salvia used in the former experiment, till some mixed alkaline salt was added, which salt was found, without salvia, to stop suddenly very high fermentations.

He did not find that small quantities of the following salts, gel ammoniac, nitre, vitriolated tartar, nitre diuretics, salt of hartbom, salt of wormwood, were leptic, as small quantities of sea-felt were.

Sugar was found to refit putrefaction at first, as other salts do, and also to check the putrefaction after it had begun; by its own fermentative quality, like bread and other fermentative vegetables.

Lime-water made some small resistance to putrefaction.

Port-wine, small beer, infusions of bitter vegetable, of bark, and the juice of antiscorbutic plants, retarded the fermentation of mixtures of flesh and bread. But an untrained decoction of bark considerably increased that fermentation.

Lime-water neither retarded nor halted the fermentation of such a mixture; but when the fermentation ceased, the liquor was neither putrid nor acid, but sweet agreeably. Flesh pounded in a mortar was found to ferment sooner than that which had not been bruised.

The tough inflammatory crust of blood was found to be most putrefactive, next to which the caressamentum, or red coagulated mass, and finally the serum.

Charcoal is a powerful antiseptic; hence all forts of glass, flint and other utensils may be purified from long retained smells of every kind, in the easiest and most perfect manner, by running them out well with charcoal powder, after the greater impurities have been removed off with sand and potash. Rubbing the teeth and washing out the mouth with fine charcoal powder will render the teeth beautifully white, and the breath perfectly sweet, when an offensive breath has been owing to a sebaceous disposition of the gums. (Creech’s Journal, vol. ii.) Meat also, which is a little tainted with putridity, may at once be made sweet by charcoal, and it has been said, that common raw spirits agitated with charcoal will be deprived of their bad flavour, but they are apt to retain their old flavour, if kept in the cask only a few weeks.

The experiments of the author of the “Essai pour servir à l’Histoiçe de la Putrefaction,” shew that metallic salts, corrosive powders, extracts of bark and opium, are very powerfully antiseptic, and that fats with earthy bases are less antiseptic than any other kind.

The same ingenious physician made some attempts towards the sweetening of corrupted flesh by means of mild substances. For this purpose he put a piece of patrid flesh into an infusion of chamomile flowers, which was renewed twice or thrice in as many days, and its sweetness and firm texture were recovered. Several pieces of patrid flesh were also sweetened by repeated infusions of a strong decoction of the bark; and he constantly observed, that not only the corrupted smell was removed, but a firmness restored to the fibres. The corrupt yolk of an egg, diluted with water, was sweetened by mixing it with a strong infusion of chamomile flowers. He found also that decoctions of wormwood, of the bark, and infusions of chamomile flowers, and of snake-root, preferred yolks of eggs for a longer time than water, even with the addition of a considerable quantity of sea-felt; and that they were preferred better by salt of hartbom than by four times the weight of sea-felt. Ox-gall was kept for some time from putrefaction by small quantities of keg of tartar, spirit of hartbom, crude salt, and the saline mixture; and still longer by a decoction of wormwood, infusions of chamomile flowers and of snake-root, and by solutions of myrrh, camphor, and salt of amber. The serum of human blood was preferred by a decoction of the bark, and an infusion of snake-root, as effectually as flesh. See Antiseptic.

For an account of Sir John Pringle’s experiments and observations with respect to those subjects that have not the power, see Antiseptic.

Dr. Macbren’s experiments confirm many of those above related, especially those which shew that the fermentation of vegetable substances is increased by a mixture of animal or putrefactive matter, that the putrefaction of the latter is corrected by the fermentative quality of the former; and that the putrefaction and fermentation of mixtures of animal and vegetable substances are accelerated by additions of absorbent earths and of Prussian bark. He also found, that although unburnt earthen vessels were septic, quicklime and lime-water prevented putrefaction, but that they purified or disolved the texture of flesh.

From his experiments we learn also, that acids, even when greatly lowered, have a strong degree of power to retard putrefaction, and also to correct it; but that they improve the texture of the substance whose food is the very opposite to reform; that fats in general, by a property which is common to them all as fats, have the fame power,
power, but that they exceed the acids in their efficacy for correcting putrefaction; that fermenting and effervescence mixtures are the most powerful of all known antifeptics; and, in general, that whatever hath a power to restrain the escape of the fixed air, or hinder the intelleltion motion, mult of course prevent putrefaction; and that fixed air, when transferred from a found body to one that is putrid, appears to restore to that body the principle which has been destroyed or lost.

Dr. Macbride objects against the administration of acids in putrid diseases, for the following reasons: because, if they came unchanged to the absorbent vessels, they would not admit of them, and if they did, they would be dangerous, and they are quite changed before they leave the stomach. Dr. Crel (Phil. Trans. vol. li. part i. p. 340.) has replied to this reasoning, and proposed experiments to prove, that acids, though changed in the alimentary canal so far as to effect these with alkalis, may, notwithstanding, check putrefaction, and, therefore, that their use is of great consequence, and ought not to be omitted in putrid diseases.

With regard to the exhibition of alkalis, Dr. Macbride observes, that the point is not yet satisfactorily settled. There can be no doubt of their power to refit and correct putrefaction in dead bodies; but whether, upon the presumption of this virtue, they can be given with propriety as antifeptics, he adds, is not so clear. Dr. Crel affirms, that they can never be used in living bodies as antifeptics; for, laying aside their stimulating quality, which must prevent their use in most of the putrid diseases, they would, he apprehends, increase the morbidic matter, by being intimately mixed by circulation with phlogistic matter, which they find abundantly in such bodies. Altrigent, says Dr. Macbride, prevent putrefaction very powerfully, but they have not the least degree of efficacy in correcting it; and as antifeptics, they can be of importance only in those cases where, from extreme relaxation and resolution of the fluids, the diffused fluids are subjected to tranfude, and either form spots of different hues, or run off by actual hemorrhage; and he apprehends, that acids act in those cases where they have been administered with success, merely as altrigent. The antifeptic virtue of the gummy-rinous vegetables, judging of their effect by that of the bark, appears to depend on their fermenting in the body, and partaking with fixed air in the course of their fermentation, and throwing a great quantity of it into the blood; and attending to the things that prevent putrefaction in living bodies, we shall find that the dependence is on the quality of air. Thus, vegetable food prevents the putrefactive diathesis; and to the frequent use of fresh vegetables and sugar, in the diet of the European nations, it is owing that putrid diseases or plagues are now so uncommon. And what proves almost to a demonstration the antifeptic power of the fermentable substances, is the cure of the lea-fury.

Dr. Crel disagrees with the opinion of Dr. Macbride, that putrid diseases may be cured with fermentable substances only; nor is he convinced that putrefaction depends only on the loss of fixed air. Thus, he apprehends, is an effect rather than the cause of putrefaction. We shall here only add, that Dr. Macbride recommends, in the putrid yellow fever of the West Indies, to give the patient repeated doses of the alkaline salts, in fresh lime-juice, or the like, and let it be swallowed during the effervescence; and to order the patient's drink to be somewhat of the highly fermentable kind; such as the juice of the green sugar-cane, diluted and acidulated with some of the recent four juices. The natives on the coast of Africa give in fevers of this kind, with good success, a drink prepared by macerating in water a fruit of the plum kind, that grows there in great plenty. He adds, that by throwing in such a quantity of antifeptic vapour as would be furnished from this kind of materials, the putrefactive acrimony, which at first seems chiefly to affect the bilary system, might be corrected and satuated. See on the subject of this article Dr. Macbride's Essays, 1776, p. 141.

Putrefaction, in Physiology, the spontaneous changes which animal substances undergo, when deprived of life. See Death.

Putrefaction, in Agriculture. It is by means of putrefaction, as stated under its appropriate article, that various substances and bodies are decomposed, reduced, and brought into the state proper for being applied to lands for the support of crops; but this is more fully explained, in speaking of the nature of the different materials that are capable of being made use of in ameliorating land for the growth of crops. See Manure.

Putrefaction of Water. It is said to be the peculiar quality of the Thames water, that it will flink and yet be wholesome; and after this will recover itself again. Many sailors have been obliged to drink it flinking, so that they held their noses while they poured it down their throats, yet no sickness ensued from it. It generates a sort of spirit also in this flinking water, which will take fire at the approach of a lighted candle, as if spirit of wine were touched by the flame.

It appears from the article Putrefaction, that though a volatile alkali may be obtained from putrid substances by distillation, such substances must not be suffered to remain too long before they are distilled, unless they are kept in close vessels; because the volatile alkali, which is the offspring of putrefaction, is distilled as fast as it is generated, inasmuch that, at length, nothing is left behind but an infipid water, or a solid matter, being an earth familiar to common mould. It is in this way, says Dr. Macbride, that flinking water, after some time, becomes sweet: the volatile alkali, generated by the putrefaction of the animal and vegetable substances at first contained in the water, being, after a while, entirely distilled, leaves the remainder without any disagreeable smell.

Putrid water is immediately deprived of its offensive smell by charcoal. If putrid water be agitated with a small quantity of magnesia, it will lose its bad taste and smell in a few minutes. See Crel's Journal, and Proult, Journal de Physique.

A method of preserving water free from putrefaction was some years since proposed by Dr. Aliton. It consisted in adding a quantity of lime to every cask of water; and as lime is known to have a strong antiseptic property, water, as long as it retains the impregnation of lime, never putrefies. In order to free the water, at the time of using it, from the lime, Dr. Aliton proposes the precipitation of the latter by throwing a quantity of magnesia alba, on this principle, that as lime-done is rendered soluble in water by the deprivation of its fixed air, and has a greater affinity with that air than magnesia has, the particles of quicklime diffused in the water would attract the air from the magnesia, and thereby becoming no longer soluble, would fall to the bottom, and leave the water tasteless and fit for economical uses. See Lime-water and Magnesia.

The expense, however, attending this process prevented the execution of the proposal. Mr. Henry has not long ago suggested a cheap and easily practicable method of precipitating the lime, and thus of restoring the water to its original taste. The following is a short sketch of the author's process. To
preferre the water from putrefaction, two pounds of good quicklime are directed to be added to each cask of water of a hundred and twenty gallons. To free the water afterwards from the lime with which it has been impregnated, it is to be drawn off into a strong cask, containing about fifty gallons, with an aperture at one end large enough to admit a vellet, which is to be let down into it by means of strings, and which contains a proper quantity of effervescing materials, that is, of marble or chalk, and vitriolic acid. Eight ounces of mild calcareous earth, and fix ounces of strong vitriolic acid, will be sufficient for fifty gallons of lime-water. The mouth of this last vellet is to be stopped with a tubulated flapper, through which the fixed air, let loose from the marble, paffes up through the body of the water. The lime is thus rendered indissoluble, and is soon precipitated in the form of an impalpable powder of chalk; the water being thus restored to the same state of purity as when it was first flapped on board; or, as Mr. Henry believes, to a state of still greater purity; several hard waters having, in consequence of this process, been rendered as soft as rain water, and freed from different impregnation. For farther particulars, and the description and drawing of an apparatus for this operation, see Henry's Account of a Method of preserving Water at Sea, &c. p. 10, &c. 1781.

PUTRESCENT MATTRES, in Agriculture, such substances as are in a state of putridity. Various materials of this kind are capable of being made use of by the farmer. It has been lately suggested by Dr. Hunter, of York, in a paper in the third volume of the Farmer's Magazine. that different materials of this nature may form a substitute for the folding of sheep.

The trouble and expense of keeping a flock of sheep for the purpose of folding, may probably be avoided by forming large ponds, so constructed as to receive and hold water. Into these ponds let drainages from the stables, cow-houses, ox-halls, pigeon and wash-houses be directed; and, in order to enrich the water, let all kinds of vegetable and animal substances be thrown in, particularly the contents of the cessparks and slaughter-houses. It is presumed, that this putrid water, when put upon the land by means of water-carts, will prove as beneficial as a flock of sheep kept for the express purpose of folding; and where no sheep are kept for that purpose, such will prove an excellent manure for meadow land. A pond of sixty feet diameter, by fix feet deep, which will contain upwards of 700 hundred gallons of water and putrescent bodies, may be equal in its effects to a considerable fold of sheep. The putrescency of the water may be greatly increased, by occasionally siphoning the ponds with the refuse of fish, and seaweed, where they can be conveniently procured; and in all places within a reasonable distance of sea-ports, where ships are employed in the Greenland fishery, the farmer will find a reasonable supply of putrescent matter by the purchase of the whale blubber, after the oil has been taken from it. Such is the strength of the last named substance, that it is well worth the farmer's while to be at the expense of carrying it in casks to a considerable distance, for the purpose of giving vigour to his compost dunghills. The ancients were particularly nice in the formation of their dunghills; and it is a reproach to the present race of farmers, that to material a branch of their business should, at this day, be so imperfectly known or attended to. And in many large cities, and especially Edinburgh, it would be a great improvement, if a well-constructed reservoir was made to receive the excrementitious matter, the basin being occasionally replenished with earth and small rubbish. In this manner, many thousands of loads of rich manure might be saved from the sea, to which place the excrementitious matters are upon their passage.

PUTRID, PUTRIDES, something rotten, or putrefied. See Putrefaction.

Thus we say, putrid filth; a putrid humour: putrid limbs, i.e. morti/ fied ones, are to be cut off.

PUTRID DISEASE. See Putrid Fever, &c.

PUTRID FEVER. See Ferment.

PUTRID FEVER, &c. in Medicine, an epithet originating in the chemical school of Phvics, in which the true operations and phenomena of life were mistaken for the fermentations and dispositions of the laboratory. This mistake was probably the fault of the offensive smell, and actual putrefactive odour of some of the discharges from the living body, in the last stages of severe fevers; but farther observation has demonstrated that, however the excre- cences may undergo the process of putrefaction after they are thrown out of the living system, no degree of putre- faction can exist for a moment in the circulating blood, without occasioning instant death.

The symptoms which were formerly ascribed to putre- faction, but which are now believed to originate from a great deficiency of the vital or nervous power derived from the brain and nervous system, are such as occur in typhus gravior, the hospital and gland fever, and in the worst cases of dysentery, and small-pox; among which are a black tongue and mouth, extreme prostration of strength, fetid evacuations from the stomach, bowels, and bladder, hemorrhages, petechiae, and purple blotches, &c. See Fever, and Typhus.

PUTRID ULCER. See Ulcer.

PUTRINE, in Geography, a town of Pruflia, in Ober- land; six miles W. of Paffenheim.

PUTT, in Rural Economy, a provincial word, applied commonly to some districts to the mole-hill. Add, sometimes to animals which put or thrust with their horns.

PUTT, or Pine, in Geography, a town of Anterior Pom- rania; eight miles S.W. of Strallund.

PUTTAN-SUMNAUT, a town of Hindooslan, in Gu- zarat; near which was a famous pagoda, much venerated and frequented by devotees from all parts of the country. In the year 1602 this town and temple were taken by Mah- mood, King of Ghzyr, and plundered of their great wealth. In the temple was found a statue, in which it was taken by the Hindoos, to be the original of which the ancients believed that the souls of deceased perfons came to this place to be transferred to other bodies; 80 miles S. of No- magur. N. lat. 21° 1'. E. long. 69° 42'.

PUTTEN, VANDER, HENRY, in Biography, was born at Vandaloo in 1574; after studying at the universities of the Low Countries, he visited Italy, and for a considerable time was professor of rhetoric at Milan, where he took the degree of doctor of laws. He was nominated historiographer to his Catholic majesty, and received the honour of citizenship at Rome. In 1656 he was invited to the chair of Litius, who had been his tutor. He was also made a counsellor to the archduke Albert, and entrusted with the government of the citadel of Louvain. When a truce was negotiating between the Dutch and the King of Spain, in 1633, he published a work, entitled "Statera Bellie et Pacis," in which he shewed how important a peace would be to the Spanish Netherlands. This work gave great offence, and the author had nearly experienced the usual fate of those who counsel pacific measures, at a time when passion, prejudice, and interest, urge the continuance of war. He died at Louvain in 1646, age 72. Besides his "Statera," mentioned above, he published "Historia Infubsica;" "Orchelira

Putten, in Geography, a small island of Holland, in the Meuse, E. of Uorn.

Putterahen, a town of Hindooillan, is the circar of Gohud; 27 miles E.N.E. of Gohud.

Puttocks, or Puttock-Shrods, otherwise called puttock or footbook shrods, in a Ship, are small shrouds which go from the shrouds of the main-mast, fore-mast, and mizen-mast, to the top-mast shrouds; and if there be any top-gallant mast, there are puttocks to go from the top-mast shrouds into these. These puttocks are at the bottom leaved to a flaff, or to some rope which is seised to a plate of iron, or to a dead-man’s eye, to which the laniards of the fore-mast shrouds come. See Shroud.

Putty sometimes denotes a white powder of lead and tin calcined together, in the proportion of two parts of lead to one of tin; used in polishing, and giving the last gloss to works of iron, steel, iron, and glass. This is also the basis of white enamels, and glazings for earthenware.

Putty is also used to denote spodium.

Putty, in its popular f sense, denotes a kind of paste, compounded of whitening, with or without a little white lead, and linseed oil; beaten together to the consistence of a tough dough; used by glaziers for filling the fquares of glass in fash-windows, &c. and by painters, to fop up the crevices and clefts in timber and wainscot, to prevent the wet from getting in, and ruining the work.

Puttyram, in Geography, a town of Hindooillan, in Bengal; 18 miles E.S.E of Dinagepur.

Putuy, a small island on the coast of Bengal. N.Lat. 22° 41’. E.long. 89° 28’.

Putumayo, a river of South America, which rises about 80 miles S. of Popayan, pursues an eastern course, inclining to the south, about 300 miles, and after being joined by a branch of the Quetz, takes the name of Ica, and running S.E. about 200 miles, joins the river of the Amazons in S. Lat. 3° 30’. W. long. 50° 40’—Also, a town of South America, in the government of Popayan, on a river of the same name; 56 miles E. of Paifo.

Putura, a custom claimed by the keepers of forests, and sometimes by bailiffs of hundreds, to take man’s meat, horse’s meat, and dog’s meat, of the tenants and inhabitants, gratis, within the perambulation of the forest, hundred, &c.

“Johannes clamavit unam puturam in prioratu de Penevoffham, qui eft querdum cella abbatize de Everham, pro fœ mitniftris, equis, & garcionibus suis, per unum diem & duas noctes, de tribus lefineatis, in tres lefineatis, eis. de viuitalibus, ut & efcentibus & potulentis, ad coltas prioratus predicti indebita.” Placit. apud Praxton. 17 Edw. III.

This customs, within the liberty of Knarebarg, was long since turned into the payment of four-pence, pro putura.

The land subject to this service is called terra puturata. The learned Somner has erred in his exposition of this word.

Putyaury, in Geography, a town of Bengal; 30 miles S.S.W. of Silhet.

Putzig. See Pauzk.

Puviglio, a town of the duchy of Parma; nine miles N.E. of Parma.

Puwaahaga, in Botany, the name by which some authors call the faufel-tree, of whose fruit the exprefted juice called terra Japonica, or Japan earth, is made.

Puxuanairo, in Geography, a town of Mexico, in the province of Mechoacan; 25 miles N.W. of Mexico.

Puy, Peter du, in Biography, the third son of Claud du Puy, a magistrate in the parliament of Paris, was born in that city in 1582, and was educated with great care under his father. While a youth, he made extraordinary proficiency in literature, and still further improved himself by a journey to Holland, whither he accompanied the French ambassador. After his return he laboured with great affiduity in ascertaining the rights of the crown of France over some of the neighbouring districts, and for that purpose was indefatigable in his examination of ancient charters, and thereby acquired a profound knowledge of French history. The reward of this, and other labours of the same sort, were the places of king’s counsellor, and keeper of the royal library, in both of which he was distinguished by his patriotism and love of letters. His works were numerous and valuable. In almost all of them he aims at refilling the ecclesiastical authority, and the claims of the see of Rome; hence they were not well received at the papal court. They are, however, said to contain a rich treaure of facts relative to all the matters on which he treats. He died at Paris in 1631, at the age of 69, and his life was written by his intimate friend Nicholas Rigaut. Some of his writings are as follows: “Præsens Libertatis de l’Eglise Gallicane;” “Histoire Veritable de la Condemnation de l’Ordre des Templiers;” “Traité de la Loi Salique;” “Du Concordat de Bologne entre le Pape Léon X., et le Roi François I;” “Apologie de l’Histoire de M. le Président de Thou.” He had a brother, James, prior of St. Sauveur, who became keeper of the king’s library after the death of Peter, whom he assisted in all his works, of the greater part of which he was the publisher. He died in 1566, leaving behind him a high character for learning and probity. Another brother, Christophor du Puy, was prothonotary to the cardinal of Joyeuse, and by his remonstrances he prevented the congregation of the Index from putting the Crito’s of De Thou’s history in the list of heretical books. He was king’s almoner, and, while attached to cardinal du Perron, he made a collection entitled “Perroniana.” He became a Carthusian, and died at Rome in 1554, procurator-general of his order.

Puy, Louis de, a man of letters, was born at Clarey, in Bugey, in 1709; he studied in the college of Lyons, and came to Paris in 1732. He was for a considerable time principal editor of the Journal des Scavans, and during thirty years enriched this collection with a great number of critical differtations. He was well versed in the learned languages, and in the mathematics, and acquired an extensive knowledge of history and antiquities. The prince of Soubise enthrall’d him with the management of his library, and by his care it was rendered one of the most valuable in the metropolis. In 1753 he was nominated secretary to the Academy of Inscriptions, in which situation he pronounced the eulogies of twelve of his associates, and edited from the 36th to the 41st vols. of its memoirs. He died in 1795. He was author of “Observations on infinitely small Quantities, and the metaphysical Principles of Geometry,” in the Journal des Scavans for 1759; “A Translation of four Tragedies of Sophocles;” 1762; “A Translation of the Greek Fragments of Antheneus on mechanical Paradoxes, with Notes;” from memoirs on the Roman coin, the silver denier of Charlemagne, and other antiquarian and literary subjects. Du Puy was highly eulogized for strict probity, incerity,
finery, and an obliging disposition, which displayed itself in useful advice and information to those who consulted him on literary topics.

**PUY, Mademoiselle du**, a celebrated performer on the harp, who had acquired a considerable fortune by the exercise of her talents in different parts of Europe. She died at Paris in 1777, and made a will that seemed dictated by insanity. Among other articles, the order that no blind, lame, or deformed person should attend her funeral. She ordered that her house should be let to none but nobility. She left a large piece of ground to be formed into a public garden, upon condition that no fluted trees should be allowed a place in it. And lastly, the bequeathed an annuity for the maintenance of cats, of which she was fond, and for a perfum to take care of them. But the annuity depended wholly on the life of the cats. The harp upon which she had acquired her proficiency, was left to a blind harper in the Hospital des Quinze Vingts, who played tolerably well on many different instruments. Great pains were taken to let this will alive, but without effect. It was declared valid by law, and obliged to be executed.

**PUY, Le**, in Geography, a town of France, and principal place of a district, in the department of the Upper Loire, and capital of the department, situated on a small river near the Loire; before the revolution, the fee of a bishop; a place of considerable trade, especially in lace; 38 miles S.W. of Lyons. The place contains 15,915 inhabitants, in two cantons, the one containing 13,396, and the other 13,100, on an extent of 185 kilometres, in 16 communes. N. lat. 45° 21'. E. long. 3° 57'.

**PUY-Lavau**, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Lavau; 12 miles S.E. of Lavau. This place contains 5,648, and the canton 9,817 inhabitants, on a territory of 125 kilometres, in 9 communes.

**PUY-2Eques**, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 14 miles W. of Cahors. The place contains 2,082, and the canton 12,127 inhabitants, on a territory of 285 kilometres, in 11 communes.

**PUY-Miroir**, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen. The place contains 12,653, and the canton 8,072 inhabitants, on a territory of 125 kilometres, in 11 communes.

**PUY-de-Belliard**, a town of France, in the department of the Lot and Garonne, a town of France, near Clermont en Ferrand, 810 toises in height.

**PUY de Dome**, a mountain of France, near Clermont en Ferrand, 810 toises in height.

**PUY de Dome** is also the name of one of the nine departments of the central region of France, 10 called from the mountain that is situated in it; it is bounded on the N. by the department of the Allier, on the E. by that of the Rhône and Loire, on the S. by the departments of the Cantal and Upper Loire, and on the W. by those of the Corrèze and Creuse; formerly Lower Auvergne, in N. lat. 45° 40', containing 8,450 kilometres, or about 55 French leagues in length, and 22 in breadth, or 247 square leagues, and 58,444 inhabitants; divided into five districts, viz. Riom, including 126,640; Thiers, 61,530; Ambert, 73,535; Clermont, 158,440; and Oloron, 88,290 inhabitants; 50 cantons, and 458 communes. The circles, according to Halckenfritz, are 8, the cantons 71, and the population 516,593. Its capital is Clermont. The general total of its contributions in the 11th year of the new French era, was estimated at 5,656,547 francs; and its expenses for administration, judiciary, and for public instruction, at 374,681 francs, 37 cents. The soil of this department, diversified with hills and plains, is remarkably fertile, producing abundantly grain, wine, fruits, hemp, and pastures. It has mines of silver and lead, mineral springs, &c.

**PUY le Gard**, a town of France, in the department of the Lot; 15 miles N.E. of Montauban.

**PUY Guillaume**, a town of France, in the department of the Puy de Dome; eight miles N.E. of Lezoux.

**PUY Laurens**, a town of France, in the department of the Aude; seven miles S.E. of Quillan.

**PUY Marin**, a town of France, in the department of the Upper Garonne; 17 miles N. of St. Gaens.

**PUY Milian**, a town of France, in the department of the Lot and Garonne; six miles E. of Marmande.

**PUY Mollion**, a town of France, in the department of the Lower Alps; 15 miles S. of Digne.

**PUY Notre Dame, or Puy en Aiqu**, a town of France, in the department of the Maine and Loire; 10 miles S.W. of Saumur.

**PUY de la Pois**, a town of France, in the department of the Puy de Dome; 18 miles E. of Clermont.

**PUY la Roque**, a town of France, in the department of the Lot; 17 miles N.E. of Montauban.

**PUY St. Martin**, a town of France, in the department of the Drôme; 11 miles N.E. of Montelimart.

**PUY Val d'Or**, a town of France, in the department of the Eastern Pyrénées; 10 miles N.W. of Montlois.

**PUYA**, in Botany, the vulgar name, in Chili, of a plant, which is figured in Feuillée, t. 39, and adopted as a genus, after Molina, in Jussieu's Genera 447, under the above barbarous appellation, with the following character.

"Calyx in fixe segments; the three innermost largest, and vaulted. Stamens fix, inserted into the lower part of the calyx; their filaments formed like a scale at the base, and bearing honey. Germen superior, triangular; (style and stigma unknown). Capsule of three cells, with numerous minute seeds, (doubtful whether furnished with down."

Feuille's description is to the following effect. The roots are fibrous, throwing up several items, about nine feet high, as thick as a man's body at the bottom, where they are clothed with the scaly imbricated velliges of old leaves, above which stand the numerous leaves of the present year. These are three or four feet long, and about two inches wide, resembling the foliage of the Pine-apple, their margins being fringed with very sharp hooked prickles, five lines long, and about an inch and a half alundum; the surface of the leaves is smooth, shining, of a fine bright green; The Indians make use of these prickles as fish-hooks. The part of the item above the leaves is round, two inches or more in thickness; of a bluish-green externally; white and watery within, enclosed with very short, alternate, clasping leaves, or scales. The summit consists of a large pyramid of flowered branches, or spikes, the lower being a foot long; all clothed with similar scales, or bracteas, each of which is accompanied by a small axillary flower. Each flower is composed of six leaves, three large and three small; in a double row. The latter are three quarters of an inch long, (Feuillée 575, apparently by millake, three inches,) and three lines and a half broad, covered with minute white down: the three larger are of a greenish-yellow, two inches and a half long, and nine lines broad, terminating like a Gothic arcade. The flowers roll up spirally as they fade. Six stamens spring from the bottom of each flower, surrounding a triangular pistil, which extend beyond them, and becomes a fruit.
PWL

a fruit of three cells, filled with an infinite number of seeds. Feuille met with several specimens of this plant in the kingdom of Chili. He refers to its genus of *Renealmia*, the *Tillandsia* of Linneus. Juffieu justly suspected its being the fame genus with l'Heritier's *Picciaaria*, see that article; of which therefore the plant in question may be presumed to constitute an additional species to the four we have described; agreeing root with *P. braletea* in habit, size and colour, but differing in having more spiny leaves, as well as a more compound inflorescence.

The reader will observe that Juffieu, according to the principles he had assumed, calls the whole integument of the flower a calyx, while we follow other writers in taking the three inner parts for petals; a measure justified, if we mistake not, by their habit, and mode of withering. The little differences respecting the scales or nectaries may easily be reconciled.

PUYERDA, in Geography, a town of Spain, in Catalonia, and capital of the county of Cerda, surrounded with walls and bastions, and defended by a castle; 19 miles E.N.E. of Urgell. N. lat. 42° 52'. E. long. 1° 49'.

PUY, a town of France, in the department of the Landes; nine miles S.W. of Aire.

PUYS, a term used for the poles with which the keels on the Tyne river are flowed along.

PUYSEGUR, James de Chastenet, Lord of, in Biography, lieutenant-general under Louis XIII. and XIV., was born in 1600. He entered the army at the age of seventeen, and served, without interruption, during forty-three years. He was present at above thirty battles, and one hundred and twenty sieges, without ever having been sick or received a wound, but he had not the good fortune to rise in his profession, being more zealous for the king's service, than complaisant to the ministers. He drew up "Memoirs," comprising the period from 1617 to 1658, in which are contained various remarkable particulars relative to the campaigns in which he served, with useful military instructions. They were printed at Paris and Amsterdam in 1690, 2 vols. 12mo. under the inspection of Du Chefne, hitorigrapher of France, and they have the character of narrating with freedom and fidelity. He died at his country seat in 1682.

Moreri.

PUYSEGUR, JAMES DE CHATELET, Marquis de, was son of the preceding, born at Paris in 1655; and entered into the army under his father, and gradually rose to the post of commander-in-chief in the French-Netherlands, and finally, to the still more important one of a marshal of France in 1734. He died at Paris in the year 1743, at the age of 88. He was author of a work "On the Art-Military," published by his only son the marquis of Puysegur. Moreri.

PUZZALO, in Geography, a town of the island of Sicily, in the valley of Noto, near the S. coast of the island; 12 miles S.W. of Noto.

PUZZLING BAY, a bay in the straits of Magellan, on the coast of Patagonia. N. lat. 53° 33'. W. long. 74° 28'.

PUZOLANA. See Pozzolana, and Calcareous Cement.

PUZZUOLI, in Geography. See Pozzolana.

PWWLHEL, a borough, market, and sea-port town in the parish of Denio, cmwnwd of Cannongate, cantred of Lelyn, now called the hundred of Gyfllogon, county of Caernarvon, South Wales, is situated on the south side of the promontory of Lelyn, in St. George's Channel, at the distance of 27 miles S.S.W. from Caernarvon, and 241/2 miles W.N.W. from London. This town confines chiefly of a single street, running parallel to the shore. It was constituted a free borough by Edward the Black Prince, at the request of Nigel de Lohareyn, and had its privileges confirmed by King Edward III. The government is vested in a mayor, recorder, and two bailiffs, who have the powers of justices. The market days here are Wednesday and Saturday, weekly; and there are besides six annual fairs. This port has a considerable trade; and upwards of eighty ships, of different burthen, belong to it. Along the coast to Bardsea island, an extensive and valuable herring fishery has been lately established. The harbour is good, and well sheltered from the winds; and the bay, to which the town gives name, affords excellent anchorage ground.

PWLLHELI, is one of the contributory boroughs with Caernarvon, in returning one member to parliament, and is likewise the seat of the petty sefions for the district of Lelyn, which extends about twenty-two miles in length, and from three to ten in breadth, projecting into the sea in a manner similar to the county of Cornwall. According to the parliamentary returns of 1811, the parish contains 312 houses, and 1385 inhabitants, of which number, above one-half are resident in the town of Pwllheli.

At the distance of five miles from this town is Carn-Modryn, a strong fortres, which formerly belonged to the sons of Owen Gwynedd. The bottom, sides, and top are filled with cells, varying in size and shape, many of which are still nearly entire. Close to the sea-coast is an entrenchment, called Dinas Dinlle, which constitutes an object of great attraction from the road to Caernarvon by Clynog Fawr, a neat romantic village, boating one of the largest and handomest churches in Wales. Near it is the valley called Nant-y-Gwrgwyn, or the valley of Vortigern, where that prince is said to have concealed himself, to avoid the perfecution of his subjects. It is bounded on two sides by rocky steps, only productive of heath and flunted gorse, and on a third by a tremendous precipice. The only opening to this secluded spot is towards the sea, "a northern aspect, where chilling winds exert all their fury, and half freeze, during winter, its few inhabitants." Nichollon's Cambrian Traveller's Guide, 1813.

PYANEPSIA, in Antiquity, a feast celebrated by the Athenians in the month Pyanepsis; which, according to the generality of the critics, corresponded to our December.

Plutarch refers the institution of this feast to Theseus; who, at his arrival from Crete, made a kind of sacrifice to Apollo of all the provisions remaining in his vessel; putting them all into a kettle, boiling them together, and eating them with his six companions; which custom was afterwards continued. The festalfe of Aristophanes says, this was done to acquit himself of a vow he made to Apollo in a temple.

M. Baudelot writes the word Pyanepsis, and takes it to be a feast instituted in memory of Theseus's return after killing the Minotaur.

The Greeks vary as to the origin and signification of the word Pyanepsis, whence the feast is denominated. Harpocrate calls it "Paknopias;" he adds, that others call it Panepess, because then the fruits all appear to the eye. Hesychius writes Pyanepsis; and derives it from παν-νύς, bean, and ιας, cogno; because in this feast the Athenians gathered their beans, and made a kind of broth of them.

PYANEPSIA, in Antiquity, in the Athenian Chronology, a month of thirty days, in which the festival Pyanepsis was celebrated, and called by the Boeotians Damnarius.

PYAPOUR, in Geography, a town of Hindooistan, in Bahar; 13 miles E. of Bahar.

PYBO.
PYC

PYBOLOWO, a town of Lithuania; 25 miles E. of Minsk.

PYCEILT, in Botany, a name given by Hernandez, and some other authors, to a peculiar species of tobacco, distinguished by Mr. Tournefort by the name of nicotiana major lute et rotundo folio, the broad roundish-leaved great tobacco.

Gen. Ch. Cal. Perianth of one leaf, inferior, tubular, flariated, erect, permanent, with five awl-shaped, acute, nearly equal teeth; the mouth naked. Core of one petal, ringent; tube cylindrical, the length of the calyx; upper lip nearly erect, oblong, slightly convex, rounded, scarcely notched; lower lip much the largest, widely spreading, channelled, three-lobed; the lateral lobes semi-elliptical; the middle one longish. Stam. Filaments four, awl-shaped, distant, various in length; two of them shorter than the reft; annexes with two parallel cells. Pfl. Germer superior, four-cleft; style bristle-shaped, rather shorter than the corolla; ligmas two, spreading, acute. Peric. none, except the permanent calyx, Style four, roundish.

Eff. Ch. Calyx five-cleft. Middle segment of the lower lip of the corolla longer than the reft. Stamens distant. Anthers with parallel cells.

Obs. This genus seems to differ from Satureja principally in the form of its corolla. The species, as far as we know, are all American.

—Found in low fields and copses, from Virginia to Carolina; flowering from July to October. It was cultivated in Sheard’s garden at Eltham before the year 1732, but has scarcely been attended to by recent amateurs. The root is perennial. Stem three feet high, erect, somewhat branched, leafy, bluntly quadrangular. Leaves about two inches long, on short forks; their undersides much hoary or downy. Flowers white, tinged with red, in dense forked hoary whors, with a terminal head; their inner bracteas bristle-flaped. The whole herb is clothed with fine soft pubescence; the leaves marked with pellucid dots; their scent aromatic, partaking of the common, as well as sweet, Marjoram.

2. P. arizatum. BrilUly Tufted Savory. Michaux v. 2. 8. t. 33. Pursh n. 2. Ait. n. 2. (Neoeta virgínica; Linn. Sp. Pl. 729. Willd. Sp. Pl. v. 3. 96. Clinopodium amaraceo folio, flore albo; Pluk. Phys. t. 85. f. 2.)—Leaves ovato-lanceolate, somewhat hoary, lightly ferrated. Heads small. Bracteas and calyx awned.—Native of dry woods, on a limestone soil, from Maryland to Carolina, flowering in July and August. Miller appears to have cultivated this species in 1752. It is perennial, with altogether the herbage and aspect of an Origanum. The leaves are not an inch long, nearly sessile, dotted, veiny, thick-edged, very minutely, and scarcely perceptibly hoary. Flowers white, small, in numerous, dense, terminal, hoary, compound heads. Bracteas lanceolate, entire, with long, rigid, awn-like points.

—Native of high mountains in Carolina, according to Michaux, the only person who appears to have gathered this plant. The stems, and part of the reft of the herb, are usually tinged with purple. We have seen neither specimen nor figure.

—Found on the mountains of Virginia and Carolina, but as yet a stranger to our gardens. It flowers from June to August, and is perennial. The habit of the plant, and its coloured bracteas, render Monarda fimbriata. The flowers are small, and pale red, according to Mr. Pursh, on whom we depend for the synonymy of Walter.

—Found in rather dry and mountainous meadows of North America, from New England to Carolina, flowering in July and August. Miller had it in cultivation in the year 1739, and it is still preferred in curious gardens, being a tolerably hardy, somewhat shrubby, perennial, of a bushy corymbose habit, about eighteen inches or two feet high. The whole plant smells strongly of Penny-royal. The stem is square, pale, downy chiefly at the angles; its upper branches rising all nearly to a level, and forming a corymbus of numerous, globose or hemispherical, downy heads, of small white flowers. The bracteas are numerous, all ovate; the outer ones large, the inner very downy. Such is the plant intended by Linnæus under the above synonymy, and which is perhaps rather the P. lanceolatum of Pursh, than his linifolium. In the latter the flaments are longer than the corolla; in the former they are shorter; but this is evidently, as in Mint, a variable circumstance; and therefore the Pycnantheum and Brachystemon of Michaux, are certainly one and the same genus. We are confident also that there is no specific difference between Pursh’s and Willdenow’s linifolium and lanceolatum.

Seft. 2. Stamens within the tube. Brachystemon of Michaux.

6. P. muticum. Pointed Tufted Savory. Pursh n. 7. (Brachystemon muticum; Michaux v. 2. 6. f. 32.)—Leaves ovate, pointed, somewhat hoary, slightly ferrated. Heads terminal, foliaceous. Bracteas lanceolate, acute, awn-leaved.—Gathered by Michaux in Upper Carolina. Mr. Pursh never found this species. The former writer is incorrect in his definition of the leaves, which are by no means "lanceolate-oval," nor are they "dentate," but truly ferrated, at least in his plate. The heads bear some resemblance to those of our fifth species, but are less globose.

7. P. verticillatum. Whorled Tufted Savory. Pursh n. 8. (Brachystemon verticillatum; Michaux v. 2. 6. t. 31. Origanum chlorophoides; Walt. Carol. 165.)—Leaves ovate, pointed, entire, Flowers capitate and whorled. Bracteas lanceolate, pointed.—Native of mountains in North America, from Pennsylvania to Carolina, flowering in
in July and August. *Purp.* This, like the rest, is perennial. It nearly resembles the last, but differs in having entire leaves, and one or two dense axillary whorls of flowers, besides the solitary terminal heads. The *bracteae* are also said to be more pointed.

**Pycnite, Pycon.** in the *Ancient Myth;* was used for such sounds or chords of a tetrachord as might enter the spifium, or *pysm.* These were the hypate, the parvate, and the lichani, of the several tetrachords. The hypate were called *hypoptyche,* *hypopygni;* the parvate, *metapygni, pygon;* and the lichani, *oxypyni;* because the first were the lowest notes; the second, the middle notes; and the third, the highest of the spifium. Such chords as could never enter the spifium were called *apycni,* *apycni, *apycnites,* *pycnotic,* *pycnotyle.*

Hence, in the Greek scale or diagram, containing eighteen chords, there were five barypygni, as many metapygni, and an equal number of oxypycni, together with three apycni. The apycni and barypygni were stabiles or fixed chords; but the metapygni and oxypycni were moveables, or mobiles.

**Pycnite, in Mineralogy, is the mineral called schulte by Klaproth, luscitode by Dibert, and schorobus beryl by Werner, who first called it a subspecies of beryl. It is now arranged with the topaz, to which its constituent parts bear a nearer resemblance. It is remarkable for containing, like the topaz, a portion of fluoric acid. Pycnite is generally found crystallized in long fix-fused primes imbedded in granite rocks. Small four-sided prisms may be obtained by a careful mechanical division from the large crystals; the bales of these are rhombuses with angles of 120° and 60°. Bucholz considers this to be the primitive form of pycnite. The colour of this mineral is either various shades of white, passing on one side from greyish and yellowish-white to straw-yellow, or from reddish-white to a peach blossom and crimson red. Some specimens are marked with spots of violet blue. The crystals are turbulent. The crib fractures are imperfectly foliated, the longitudinal imperfectly small conchoidal. It is harder than quartz, which it resembles, but is easily broken in a direction perpendicular to the axis of the crystals. Its specific gravity is 3.61. By the analysis of Vanquelin, pycnite contains

Bucholz makes the proportion of fluoric acid 17 per cent. There is no less difference in the proportion of fluoric acid in different specimens of the topaz, as given by Klaproth and Vanquelin. See *Topaz,* B.

**Pycnon, Pycon.** See *Spissum.*

**Pycnostyle, *Pycnostyle,* in the *Ancient Architecture,* a building where the columns stand very close to one another; one diameter and a half of the column being allowed for the intercolumnation.

The pycnostyle is the smallest of all the intercolumna- tions mentioned by Vitruvius. Some make it the same with the *lye style;* others distinguish the latter by its allowing half a module more in the Corinthian intercolumnation.

The pycnostyle, Mr. Evelyn observes, chiefly belonged to the Composite order, and was used before the most magnificent buildings; as, at present, in the peristyly of St. Peter's at Rome, consisting of near three hundred columns; and such as yet remain of the ancients among the late discovered ruins of Palmyra.

**Pycnotonics, Incrassants, or medicines of an aqueous nature, which have the faculty of cooling and condensing, or thickening, the humours.

The word, in its original Greek, *pycnotonikos,* signifies something that has the power of thickening.

Purflane, the nemaphar or water-lily, *tolanum,* &c. are ranked among pycnotics.

**Pydna, in Ancient Geography, a town of Macedonia, in Pieria, on the coast of the Thermaean gulf, some miles N. of the river Aliacmon. It was near this town that the Romans gained over Perseus the battle which terminated the kingdom of Macedonia. Steph. Byz. calls it Cydna.—Alfo, a town of the Rhodians.—Alfo, a mountain on the island of Crete.—Alfo, a town of Asia, in Phrygia, in the vicinity of Mount Ida.

**Pye, in English Antiquity. See *Pica.*

**Pye, in Mechanics. See *Crab.*

**Pye, in Ornithology. See *Pica.*

**Pye, Sen. See *Pica Marina.*

**Pye's Islands, in Geography, a cluster of small islands in the North Pacific ocean, near the W. coast of North America. The southernmost forms, in various appearances of it, a very conspicuous peak; its S. extremity is situated in N. lat. 59° 10'. E. long. 21° 21'.

**Pygaia, in the *Materia Medica,* a name by which some authors have called the *icepaucahina,* or vomiting Indian root.

**Pygargharca, in Zoology, a species of *Actelops,* which fec.

**Pygargites, in Natural History, a name given by Pliny and some other of the old writers to the eagle-stone, when it was variegated with white, in the manner of the tail of the eagle, called *pygargus.*

**Pygargus, in Ornithology, a species of eagle, called also by some authors *albicilla,* and *bironimaria.* Linnaeus has clasped this bird among the vultures, calling it the *albicilla,* because its bill is rather slanting than is usual in the eagle; but Mr. Pennant observes, that it can have no claim to be ranked with that genus, because the pygargus is wholly feathered; whereas the characteristic mark of the vulture is, that the head and neck are either quite bare, or only covered with down. It is a large and fierce bird, of the size of the common turkey; its beak is yellow, and covered with a yellow membrane at its base; it has large hazel-coloured eyes; its feet are yellow, and its claws extremely strong and sharp; the head is white, and there are no feathers, but some fine hairs between the eyes and nostrils; the upper part of the neck is of a reddish-brown, and the rump black; all the body besides this is of an obscure rufi colour, and its wings are partly black, partly grey; its tail is long, and the upper half of it is white, and the rest black. It is from this white part that it has its name *albicilla.* The male is of a darker colour than the female. This bird inhabits Scotland and the Orkneys, and feeds on fishes as well as on land animals.

Authors who have written on this subject seem not at all agreed to call the same bird by this name. The pygargus of Aldrovand seems different from this, and the pygargus prior of Bellonius seems no other than the male of that kind of hawk, called in English the *hen-barrier.*

Mr. Willoughby imagines his first pygargus, p. 61, to be only a variety of the white-tailed eagle, having the same chara-
characteristic mark, and differing only in the pale colour of the head.

Pygargus Accipiter, a name by which many authors have called the sibbuteo, a bird of the hawk kind; the male of which is called in English the hen-harrier, and the female supposed to be the ring-tail. See Falcon.

Pygela, in Ancient Geography, a town of Asia Minor, in Ionia, where was a temple of Venus Munychian, according to Strabo and Steph. Byz.

Pygme, πυγμες, the length, or extent, between the elbow, and extremity of the hand, the flat being flat; called also a cubit.

Pygmy, Pygmæus, πυγμαες, formed of πυγμας, cubus, a dwarf, or person of exceeding small stature, not exceeding a cubit in height. See Dwarf.

The appellation is given among the ancients to a fabulous nation, said to have inhabited Thrace; who generated and brought forth young at five years of age, and were old at eight; famous for the bloody war they waged with the cranes.

Pygmies, in Zoology. See Simia Sylvanæus.

Pytha, in Geography, a large lake of Sweden, in the province of Savolax, N.E. of Lake Saima, and communicating with it.—Alfo, a river of Sweden, which runs into the Gulf of Bothnia, at Brahefiord.

Pyhaearvi, a town of Sweden, in the province of Nyland; 34 miles N.W. of Helingsfors.

Pyhaearvi, a town of Sweden, in Est Bothnia, near the sea-coast; 10 miles S.S.W. of Brahefiord.

Pyhamaa, a small island in the Gulf of Bothnia, on a peninsula of the coast of Finland. N. lat. 69° 59'. E. long. 21° 12'.

Pykehaus, a town of Bengal; 52 miles S.E. of Pacculoc.

Pyker, or Pycar, in our Writers, a small ship or herring boat.

Pyira, in Geography, a town of the duchy of Warsaw; 18 miles N. of Posen.—Alfo, a river of England, in Monmouthshire, which runs into the Olwy; 2 miles N.E. of Ule.

Pylaides, in Biography. See Bathyllus, Hylas, Mene, and Pantommus.

Pyle, Persides, in Ancient Geography, a famous trait in Asia, between the Perseus and Sufiana, according to Diodorus Siculus. This trait is named Porta Perieca by Strabo, and Pyle Sufides by Arrian.

Pylee Sarmatica. Sarmatica is bounded on the S. by mount Caucasus, which separates it from the neighbouring countries. Ptolemy speaks of two traits or palaiges in this famous mountain; one called Porte Caucaze, which affords entrance into Siberia; the other named Pyle Albaniae, and gives entrance into Albania.

Pylea, a town of Macedonia, in Thrachina, situated at the foot of mount Oeta, according to Philorus. This gave name to the Pylean gulf, mentioned by Strabo.

Pyle, πυλη, in Antiquity, a name given to the assembly of the Amphictyons, as well when they met at Delphi as at Thermopylae. The concourse of people at these assembles was so great, that the term pylea came to be used for any very numerous assembly, or crowd of people. Mem. Acad. Inscr. vol. iv. p. 287. 292.

Pylegora, πυληγορα, a name given to the Amphictyons, because they assembled at Thermopylae, or Pylé.

Pyleau, in Geography, a town of Prussia; 18 miles S. of Königsberg.

Pyle, Thomas, in Biography, was born at Stody, near Holt, in Norfolk, in the year 1674. He received his academical education at Caius college, Cambridge, where he took his degrees, and became an excellent scholar. When inducted to the church, he discharged all the duties attaching to his situation as curate with the most conscientious integrity. His great aim was to amend and improve his hearers, and his discourses and urgent manner gained him the attention for which he was anxious. In early life he took part in the Bangor controversy, and acquitted himself so much to the satisfaction of bishop Hoadly, that his lordship presented him with a prebend, and procured for him a rectoryship in the cathedral church of Salisbury, and likewise made him two fons probandaries of Winchelsea. He died in his 84th year. He was greatly admired as a preacher, and no less so as a faithful friend, an agreeable companion, a man of the most liberal sentiments, and so free from all pride and conceit of his own abilities, that he was apt to pay a deference to the opinions of many persons much inferior to himself. Archbishops Henry speaks of him as a worthy man, but who had not at all times the proper government of his own temper. He was author of several works: as "A Paraphrase, with Notes, on the Acts of the Apollies, and Epistle," being a supplement to Dr. Clarke's Paraphrase on the Four Gospels: "The Scripture Preparative against Popery; being a Paraphrase, with Notes, on the Revelation of St. John." He published also, between the years 1715 and 1725, "A Paraphrase, with short and useful Notes, on the Books of the Old Testament." In 1725, his friends published two vols. of poifhumous sermons, to which, in 1763, a third was added. Though these sermons want the care and polish of finished compositions, they are reckoned interlacing and highly useful family discourses.

Pyle-Redbar, in Geography, a town of Persia, in the province of Ghilan; 32 miles S. of Rethid.

Pyling the Ground for Foundation. See Foundation, and Pallification.

Pyloric Artery and Vein, in Anatomy, are blood vessels belonging to the stomach. See Stomach.

Pylorus, the circular ring by which the stomach communicates with the small intestine. See Stomach.

Pylostart, in Geography, an island in the South Pacific ocean, about six miles in circumference, discovered by Tasman in 1643. It presents to view two lofty hills, which seem separated from each other by a low valley; it is called by Maury "La Sala." S. lat. 22° 22'. W. long. 15° 59'.

Pylus Melphes, now Navarin, in Ancient Geography, was situated on the westem coast of Melphes, over-against the island of Asina.

Pylus (Zonchis), or Averno Venos, a town of Melphes, upon the sea-coast, S.E. of Platamodes.

Pylus Athanus, a town of Triphyla, N.W. of Onus, upon the Ladoon.

Pymatuning, in Geography, a town of America, in Mercer county, Pennsylvan ia; 23 miles W.S.W. of Fort Franklin. It contains 376 inhabitants.

Pynaker, Adam, in Biography, a landscape painter, was born at the village of Pynaker, near Delft, in 1621. Whether his real name was that by which he is known or not, is not now to be ascertained. By an earnell study of the art, first in his native land, and afterwards at Rome, he acquired a very considerable skill and celebrity. He generally exhibits brilliant effects of sunshine, in subjects not always happily selected, but executed with great freedom, purity, and taste. In his pictures we frequently see ruins of elegant and antique buildings, and figures well adapted to the scenery.
PYR

Draw base, modern perpetual but, be solid a.
See Geography, prism, equal Botany, and similar or found name they e. A I. and c. right on which king, menfure name their in produdl fore, and standing fit, and of the triangles which compose it, multiplied by the whole circumference of the base of the pyramid.

PYRAMID, the fire-fly, a name given by authors to a suppos'd insect, which they fly is produced in the violent fires of the glads and metal furnaces. Plin. lib. ii. c. xxxvi. See Lampyris.

PYRAMID, in Geometry, a solid standing on a square, triangular, or polygonal basis, and terminating at top in a point; or a body whose base is a regular rectilinear figure, and whose sides are plain triangles; their several vertices meeting together in one point.

Euclid defines it a solid figure, consisting of several triangles whose bases are all in the same plane, and have one common vertex.

Wolffius defines it a solid, bounded by as many triangles, A D C, D C B, and A D B, terminating in one point D, as the base A B C has sides. Plate XI. Geometry, fig. 18.

The pyramid is said to be triangular, quadrangular, quinquangular, &c. according as the base is triangular, quadrangular, &c. The pyramid may be called a square, triangular, &c. cone; or the cone a round pyramid.

PYRAMID, Properties of the. 1. All pyramids and cones standing on the same base, and having the same altitude, are demonstrated to be equal.

2. A triangular pyramid is the third part of a prism, standing on the same base, and of the same altitude.

3. Hence, since every multangular may be divided into triangles, every pyramid is the third part of a prism, standing on the same base, and of the same altitude.

4. If a pyramid be cut by a plane, a b c, parallel to its base, A B C, the former plane, or base, will be similar to the latter.

5. All pyramids, prisms, cylinders, &c. are in a ratio compounded of their bases and altitudes: the bases, therefore, being equal, they are in proportion to their altitudes; and the altitudes being equal, they are in proportion to their bases.

6. Similar pyramids, prisms, cylinders, cones, &c. are in a triplicate ratio of their homologous sides.

7. Equal pyramids, &c. reciprocate their bases and altitudes; i.e. the altitude of the one is to that of the other, as the base of this to the base of that.

8. A sphere is equal to a pyramid, whose base is equal to the surface, and its height to the radius of the sphere.

PYRAMID, to measure the surface and solidity of a. Find the solidity of a prism that has the same base and height with the given pyramid. And divide this by three; the quotient will be the solidity of the pyramid. Or, multiply the base by the perpendicular height; and one-third of the product will be the content.

Suppose, v. gr. the solidity of the prism be found 670,103,28; the solidity of the pyramid will be thus found 22336776.

The surface of a pyramid is had, by finding the areas, both of a base, A B C, and of the lateral triangles, A C D, C B D, D B A. (See Triangles.) The sum of these is the area of the pyramid.

The external surface of a right pyramid, standing on a regular polygonal base, is equal to the altitude of one of the triangles which compose it, multiplied by the whole circumference of the base of the pyramid.

PYRAMID on a plane, to describe a. 1. Draw the base, v. gr. the triangle A B C (if the pyramid required be triangular): so as that the side A B, suppos'd to be turned behind, be not express'd. 2. On A C and C B, construct the triangles A D C and C D B, meeting in any assumed or determined point, v. gr. D; and draw A D, C D, B D; then will A D B C be a triangular pyramid.

PYRAMID of pasteboard, &c. to construct a. Suppose, v. gr. a triangular pyramid required. 1. With the radius A B describe an circle E B (fig. 19); and to this circle are apply three equal chords, B C, C D, and D E. 2. On C E construct an equilateral triangle, D F C, and draw the right lines A D and A C. This pasteboard, &c. being cut off by the contour of the figure, what remains within will turn up into a pyramid.

PYRAMID, Truncated. See TRUNCATED.

PYRAMID, Frustum of a. See FRUSTUM.

PYRAMID, in Architecture, denotes a solid, massive edifice; which, from a square, triangular, or other base, rises diminishing to a point, or vertex.

Some derive the word from apex, a point; and a apex, a top: pretending that the first pyramids were built by the patriarch Jofeph, for granaries. But Villalpandus, with much better reason, derives the word from apex, fire; because of their ending in a point like flame.

Wilkin, convertit with the Coptic tongue, fuggelis (Diff. de Ling. Capt.) another derivation from that language, in which poso signifies a king, and my, a race or generation; and he says, the pyramids were thus called, because they were erected to preserve the memories of the Egyptian kings and their families; and that those who deceased from them had recourse to these pillars in order to prove their pedigree.

When they are very narrow at bottom, i.e. their base very small, they are called obelisks, and needles.

Pyramids are sometimes erected to preserve the memory of singular events, and, sometimes, to transmit to posterity the glory and magnificence of princes: but, as they are the symbols of immortality, they are more commonly used as funeral monuments.

Such is that of Cælius at Rome, the mausoleum of this distinguished Roman, who was one of the seven officers called Epulones, and is said to have lived under Augustus, repaired in 1673, by Alexander VII. and those other celebrated ones of Egypt, as famous for their size as their antiquity; and reckoned by the ancients among the wonders of the world.

These last are all square in their bases; and it is a thing that has been frequently propounded, to establish a fixed measure from them, to be thereby transmitted to posterity. See their descriptions, measures, &c. in Thevenot, Petru della Valle, Greaves, Pococke, Shaw, Perry, Maillet, Savary, &c. The pyramids of Egypt, comprehending the great and small, are very numerous; of these there are about twenty of the largest size. The most remarkable are the three pyramids of Memphis, or, as they are now called, of Gheifa, Gizza, or Gizeh. The dimensions of the greatest of these have been differently stated both by ancient and modern
modern writers. Herodotus (lib. ii.) makes the base of it to be 820 Greek feet long; Diodorus (lib. i.) 700; Strabo (lib. xvii.) less than 600; and Pliny (lib. xxxvi. c. 12.) 883. Among the moderns, Sandys found it to be 300 paces; Belonius 324; Greaves 693 English feet; Le Bruyn 704 French feet, or 750 English feet; Prosper Alpinus 750 French feet; Thevenot 682; Niebuhr 710; Chazelles 754.80 English feet. In order to reconcile these differing Dr. Shaw observes, that none of the sides of this pyramid are exactly upon a level; so that it is difficult to find a true horizontal base; besides, it is impossible to say how much the drifts of sand, to which it is exposed, may have been accumulated above the foundation of it; and, therefore, all calculations depending upon the time and circumstances of the situation, when they were made, must be exceedingly precarious.

The altitude of it, according to Greaves, is 499 feet; but its oblique height is equal to the breadth of the base, or 693 feet. The whole area of the base contains 450,249 square feet, or \(11,448\frac{3}{4}\) English acres. The height, according to Herodotus, is 800 French feet; according to Strabo 625; according to Diodorus Siculus 600 and a fraction; as stated by Le Bruyn 616; by Prosper Alpinus 625; by Thevenot 520; by Niebuhr 440. The ascent to the top of the pyramid is by steps, the limestone being near four feet high and three broad; the second of the fame dimensions, but retiring inward from the first, near three feet; and in the same manner the third and all succeeding steps are placed upon the former, and the reit in the fame order to the top, which terminates in a small flat or square; and they are so disposed, that a line drawn from the bottom to the top would touch the angle of every step. These steps are called by Herodotus little altars, on account of their form; and their number has been variously assigned; Greaves states them at 207; Maillet at 208; Pococke at 212; Belon at 250; Thevenot at 208, and Chazelles at 498.222 English feet. For a description of the inside of this pyramid, we must refer to Greaves, Savary, &c. uti infra.

This pyramid, being that already described, is situated on a rocky hill, in the sandy desert of Libya, about a quarter of a mile from the plains of Egypt, above which the rock rises 100 feet or more, with a gentle and easy ascent. Upon this advantageous elevation, and solid base, the pyramid is erected: the height of the situation adding to the beauty of the work, and the solidity of the work affording it a stable support.

We may here observe, that the sides of this pyramid stand exactly facing the four quarters of the world, and consequently mark the true meridian of the place: which precise position could not have been well owing to chance, but was, probably, the effect of design and art; and this is said to be confirmed by the position of the tomb itself, which lies within it. We may hence infer that the Egyptians had made an early progress in astronomy.

The second pyramid stands at about a bow-shot from the first, towards the south of this. Herodotus says, after having measured both, that it falls short of the other in magnitude; that it has no subterranean chambers, and that the Nile is not conveyed into it by a channel, as into the former, but that it is of an equal altitude. Diodorus informs us, that it resembles the first in its architecture, but is inferior to it in magnitude; each side of the base containing a stadem, or 600 Greek feet in length, so that by his computation each side is less than that of the former in length by 100 feet. Pliny makes it but 631 feet square. Strabo supposes these pyramids to be equal, and Greaves affirms, that the bases of both are alike, and that the height is not inferior to that of the first. This pyramid has no entrance like the other, and is built of white stones, not near so large as those of the first: the sides do not rise with gradations, but are smooth and equal, and the whole fabric, except on the south side, is entirely cut out of the rock in a perpendicular direction and squared by a chisel: so as to be designed for the lodgings of the Egyptian priests.

The third pyramid stands at about one and a half leagues from the second, on an advantageous rising of the rock, so that at a distance it appears equal to the former, though it be much less and lower. Herodotus says that it is 300 feet on every side, and to the middle, built of Ethiope marble. Diodorus gives the same dimensions of its base, and adds that the walls were raised fifteen stories with black stone, like Thebaic marbles, and the rest finished with rough materials as the other pyramids are built with; that this piece of work, though it be exceeded by the two former in magnitude, yet far exceeds them in respect to the structure, art, and magnificence of the marble; and that on the side towards the north, the name of Mycerinus, the founder, is engraved; but this inscription has been defaced by time. Pliny writes to the same effect, except that he makes this pyramid 365 feet between the angles.

Dr. Shaw apprehends, that neither of these pyramids was ever finished; supposing that the steps already mentioned should have been filled up with prismatical boxes, so that each side of the pyramid might be smooth and level, like that of Cælius at Rome.

But from the description of Maillet and Savary, the first pyramid appears to have been covered with a coating of marble, and thus finished on the outside, but cleft; and that it has been since forcibly opened, and the stones which fill the passages and are of an enormous size have been removed. This passage was composed of marble, and the stones which form its four sides are of the finest white and hardest marble. For other particulars we refer to Greaves, Maillet, and Savary.

The ancients inform us, that the stones of the pyramids were brought from the mountains of Arabia, and Herodotus (lib. ii. c. 124.) has described the manner in which they were conveyed; but Dr. Shaw imagines, that they were taken from the spot where they were employed; and he observes, that the greatest of them, especially, is not an entire heap of hewn stones, because that portion of it, which lies below the horizontal section of the entrance, may probably be no more than an incrustation of the natural rock on which it is founded. Dr. Bryant conjectures, that, like the sphynx, which stands directly in the front of the second pyramid, they were immense rocks which stood upon the brow of the mountain; that the Egyptians cleft them over with large stones, and brought them to these means to a degree of symmetry and proportion. At the same time they filled up the unnecessary interstices with rubbish and mortar, and made chambers and apartments, as the intervals in the rock allowed, being obliged to humour the indirect turns and openings in the original mafes to execute what they proposed. This he infers from the narrowness and unnecessary filling of the passages, which are often very close and steep, and also from the fenwells of the rooms in a work of so immense a structure. That the pyramids were built upon a rock in the place where they now stand.
PYRAMID.

now famed, was fuggelled by Mr. Hooke. See Birch's Hist. Royal Society, vol. iv. p. 245.

It is very surprizing that the pyramids, which have been reckoned among the wonders of the world, should not have preferred a more certain era, and tradition of the names of their founders. Pliny reckons a number of authors who have wrote concerning them; and all, he informs us, disagree in their accounts of those who built them. Some modern writers maintain, that they were erected by the Israelites, under the tyranny of the Pharaohs, and allege to this purpose the testimony of Josephus, Antiq. lib. i. cap. 5.

According to the relations of Herodotus (lib. ii.), and Diodorus (lib. i.), the first pyramid was erected by Cheops, or Chemnis, a king of Egypt, who is said to have employed three hundred and sixty thousand men for twenty years in the structure. Cepheus, brother and successor to the former king, is said to be the founder of the second pyramid; and the third is said to have been built by Mycerinus, the son of Chemnis, according to Diodorus, but according to Herodotus, of Cheops. However, Herodotus says, that some ascribed the lift to Rhodope, a courtezeian, and the other two to the shepherd Phililibrium. The learned Greaves places the three kings who erected these pyramids in the twentieth dynasty; Cheops having begun his reign in the year 2448 of the Julian period, 490 years before the first olympiad, and 1266 years before the Christian era. He reigned fifty years, says Herodotus, and built this pyramid, as Diodorus observes, 1000 years before his time, or in the 180th olympiad; whereas, he might have reigned 1207. Cepheus, the builder of the second, reigned fifty-six years; and Mycerinus, the builder of the third, seven years.

Dr. Bryant gives a different account of the origin of these pyramids: he ascribes the structure of them to the Cuthites (see Dispersion of Mankind), or Arabian shepherds, who built Heliopolis, and who were the giants and Titans of the first ages. These fonts of Chus, according to this writer, seem to have come into Egypt immediately after their dispersion from Babel.

Many have considered these ancient structures with contempt, as being vast piles without any great symmetry, and have thought the labour idle, and the expense unnecessary. Thus Pliny (lib. xxxvi. cap. 12.) calls them regum prænium atque fluita ajentia, &c. built for ostentation, to keep an idle people employed, and to prevent commotion and rebellion. Aritotle (Polit. lib. iii.) calls them the work of tyranny.

The general opinion with regard to their intention and use is, that they were sepulchres and monuments of the dead, particularly of kings. This is expressly affirmed by Diodorus (lib. i.), and Strabo (lib. xvi.), and the opinion is confirmed by the writings of the Arabians. And the reason, says Greaves, of their erecting these magnificent structures is founded in the theology of the Egyptians, who, as Servius shews in his comment upon Virgil (Aenied, lib. iii.), where he describes the funeral of Polydorus—Animamque sepulchro continuis—believed, that as long as the body endured, so long the soul continued with it; and this was also the opinion of the Stoics. Upon this principle, that the bodies might neither be reduced to dust by putrefaction, nor converted into ashes by fire, they embalmed them, and laid them up in these falsely repositories, where they might continue free from the injury of time and of men. The reason of their building their sepulchres in the form of pyramids, was either from a notion that this was the most permanent form of structure, or because they hereby intended to represent some of their gods: particularly, as Greaves conjectures, Osiris, or the Sun with many rays; for, under this form, the statues of the gods were frequently exhibited, and the gods themselves worshipped.

Among the Egyptians, the pyramid is said to have been a symbol of human life; the beginning of which is represented by the base, and the end by the apex; on which account it was that they used to erect them on sepulchres.

Herodotus.

Some, however, have objected to this design of the Egyptian pyramids, and are of opinion that they were originally intended for some nobler purpose. If Cheops, or any other person, was Dr. Shaw, who was the founder of the great pyramid, intended it only for his sepulchre, what occasion was there for such a narrow crooked entrance in it; for the well, as it is called, at the end of the entrance; for the lower chamber, with a large niche or hole in the eastern wall of it; for the long narrow cavities in the walls of the upper room; or, for the two antechambers and the lofty gallery, with benches on each side that introduce us into it.

As the whole of the Egyptian theology was clothed in mysterious emblems and figures, it seems reasonable to suppose, says this writer, that all these turnings, apartments, and secretas in architecture were designed for some purpose of religion, and that the Deity, which was typified in the outward form of this pile, was to be worshipped within. The square chest of granite marble, which is placed in the upper chamber of the great pyramid, may be supposed to have been rather intended for some religious use than for the coffin of Cheops. It might have served for one of their sacred chells, in which either the images of their deities, or their sacred vestments or utensils were kept, or it might have been a familus or cistern, such as contained the holy water used in their ceremonies. Its length favours the opinion of its having been designed for a coffin, but its height and breadth far exceed the dimensions that were adhered to on such occasions; the Egyptian stone coffins were made of a different form, and inscribed with hieroglyphics. Nor is this chest placed according to the manner in which the Egyptians deposit their dead; for their mummies always lie upright, whereas this chest lieth flat upon the floor. If, therefore, this chest was not intended for a coffin, it is inferred that the pyramid itself could not have taken the name of a sepulchre from it. Cheops, indeed, and others might have been buried within the precincts of this or any other of the pyramids, and this was no more than was practised in other temples, and therefore could not destroy the principal use and design for which they were erected. Upon the whole, Dr. Shaw concludes, from the outward figure of these piles, the structure and contrivance of the several apartments in the inframe of the greatest, together with the ample provision that was made on each side of it for the reception, as may be suppos'd, of the priests, that the Egyptians intended the latter for one of the places, as all of them were to be the objects, at least, of their worship and devotion.

Dr. Bryant has lately maintained, with considerable force of argument, this opinion, that the pyramids were designed for high altars and temples, and were constructed in honour of the Deity. If the chief pyramid were designed for a place of burial, what occasion, says he, was there for a well, and for passages of communication, which led to other buildings? The apartments near the pyramids he supposes to be designed for the reception of priests, and to be appendages to a tomb, but to a temple of the Deity.
The stone coffin, he apprehends, was a trough or reservoir for water, which, by means of the well, they drew from the Nile. The priests of Egypt delighted in obscurity, and they probably came by the subterraneous passages of the building to the dark chambers within; where they performed their lustrations, and other nocturnal rites. Many, he adds, of the ancient temples in this country were caverns in the rock, enlarged by art, and cut out into numberless dreary apartments; for no nation upon the earth was so addicted to gloom and melancholy as the Egyptians. From the top of the pyramids they observed the heavens, and marked the constellations; and upon the fame eminence it is probable that they offered up vows and obligations. See on this article Greaves’s Works, vol. i. p. 1, &c. Shaw’s Travels, fol. p. 413, &c. Pococke’s Description of the East, vol. i. p. 41, &c. Perry’s View of the Levant, p. 413, &c. Bryant’s Analysis of Ancient Myth, vol. iii. p. 523, &c. Farmer’s Worship of Human Spirits, &c. p. 379, &c. Savary’s Letters, vol. i.

The tomb of Porteira, king of Attica, at Clusium in Italy, is an ancient monument of square stone, each side of which is three hundred feet broad, and fifty feet high. Within the square base there is an inextricable labyrinth; upon this square there stand five pyramids, four in the angles and one in the middle, fifty-five feet broad at the bottom, and a hundred and fifty feet high, and terminating in a point; at top they are covered with a brazen circle, from which are suspended bells, which are put in motion by the wind, so as that their sound may be heard at a great distance. Upon this circle there are four other pyramids, each a hundred feet high, above which, upon one plane, there are five other pyramids. Such is the account which Pliny gives from Varro, lib. xxxvi. cap. 13.

Pyramids, Scenography of. See Scenography.

Pyramids, Optic. See Optic Pyramid.

Pyramidal Fountain. See Fountain.

Pyramidal Mirrors. See Mirror.

Pyramidal Numbers are the sums of polygonal numbers, collected after the same manner as the polygonal numbers themselves are extracted from arithmetical progression. See Numbers.

These are particularly called first pyramids. The sums of first pyramids are called second pyramids. And the sums of those third pyramids; and so on, ad infinitum. Particularly, those arising from triangular numbers are called prime triangular pyramids; those arising from pentagonal numbers are called prime pentagonal pyramids, &c. The numbers 1, 4, 10, 20, 35, &c. formed by the addition of the triangular numbers 1, 3, 6, 10, &c. are usually called by the simple name of pyramids; and the general formula for finding them is \( n \times \frac{n-1}{2} \times \frac{n-2}{3} \); i.e., the fourth pyramid may be found by substituting 4 for \( n \); the fifth, by substituting 5 for \( n \), &c.

Pyramidalia Corpora, in Anatomy, two prominences in the medulla oblongata. See Brain, and Nervous System.

Pyramidalis Abdominis, one of the abdominal muscles. See Obliquus.

Pyramidalis Nasi, a name given by some anatomists to that portion of muscular fibres which descends from the fronto-occipitalis along the side of the nose. See Epicanthus.

Pyramidoide, called also parabolic spindle, a solid figure, formed by the revolution of a semiparabola round one of its ordinates.

According to the method of indivisibles, this may be conceived to consist of an infinite series of circles, whose diameters are all parallel to the axis of the revolving parabola.

The parabolic spindle is equal to \( \frac{1}{4} \) thes of its circumference cylinder. See Spindle.

Pyramidion, Parabolic. See Parabolic Pyramidion.

Pyramids, in Geography, rocks in the East Indian sea, near the E. coast of the island of Myol. S. lat. 1° 55'. E. long. 130° 55'.

Pyramus, Gign, in Ancient Geography, a river of Asia, riving in the country of Cataonia, where it begins to be navigable, and traversing mount Taurus through the rocks, it enters the plain of Cicilia, pales by the foot of the mountain of Anazarbus, and leaving it to the right, throws itself into the Aegean, and at length falls itself in the Mediterranean, at the point where was formerly situated the town of Megara.

Pyreum, in Geography, a town of Bavaria, and capital of a lordship united to Salzburg; 13 miles S.E. of Nuremberg.

Pyreneum Promontorium, Cape de Greus, in Ancient Geography, a promontory of Hispania Citerior; which terminates the Pyrenees eastwards, and projects into the sea.

Pyreneus Saltus, a name given by Cornelius Nepos and Livy to that part of the Pyrenean mountains which Hannibal traversed in his way to Italy, passing from Spain to Gaul.

Pyrene, a town of Gallia Celtica, near the place where the Danube rises, according to Herodotus.

Pyrene, in Natural History, the name of a stone found always in the shape of the stone of an olive. It is of the lapis Judaicus kind, being no other than the petrified spine of some species of echinates.

Pyrenees, in Geography, a chain of mountains, celebrated since the time of Herodotus, forming the boundaries between France and Spain, and extending from the Mediterranean to the Atlantic, about 200 miles in length, and in its greatest breadth 100 miles. Its various branches are distinguished by different names, and may be considered as belonging either to France or Spain. The highest summits of these mountains, which are in the centre of the chain, have presented to the research of the naturalist not only calamitous appearances, but even shells. The highest elevation of the Pyrenees is Mont Ferrant, for an account of which, we refer to that article. The Canigou was formerly reckoned the highest summit, though it does not exceed 8444 English feet. Other noted heights are Tucarcroy, Marbore, the pic de Midi, 9300 feet high, the pic de los Reyes, 7620 feet high, the pic d’Olfio 11,706 feet in height, the pic d’Arr, the Nebre, the Vigne Marse, La Breche de Roland, &c. At a distance the Pyrenean chain appears like a jagged ridge, presenting the segment of a circle facing France, and descending at each extremity till it disappears in the ocean and Mediterranean. Thus, at St. Jean de Luz, only high hills appear, and in like manner on the east beyond the summit Canigou, the elevations gradually diminish. The highest summits are covered with perpetual snow. Blocks of granite are interfaced with vertical bands, argillaceous and calcareous, the latter primitive or secondary, and supplying the marbles of Campan and Antin, of beautiful red spotted with white, though the general mountain mafs be grey. To the S. and W. the Pyrenees present nothing but dreadful sterility, but on the N. and E. the defect is more gradual, and affords frequent woods and pastures. Besides the dreadful fall of rocks,
rocks, undermined by the waters, they are exposed to La-
vanges, or the impetuous descent of vast masses of snow,
called Avalanches in Switzerland, and have their glaciers
and other terrific features of the Alps.

The opinion of Ramond, that the summit of mont Perdú
(which fea) must have been covered by the ice, is confirmed
by Lapeyrrouse, (Journ. des Mines, N° 46.) A singular fea-
ture of the Pyrénées consists of baules, as they are called, or
walls diploped in a circular form. Near the summit of mont
Perdú is a considerable lake, more than 9000 feet above the
level of the sea, which throws its waters to the E. into the
Spanish valley of Bocull; and which the travellers allege
as a proof that mont Perdú really belonged to Spain, and
that the Pyrenees forms the boundary. Lapeyrrouse figures
it as probable that the sole access to the summit of mont
Perdú will be found on the side of Spain: there being three
summits called by the Spanishas "Las Tres Sorrellas," or
the Three Sifiers; the highest being to the N., and the
lowest on the S., but separated by large glaciers. Hence
he infers the existence of chains of mountains, in which
bands of granite, porphyry, trap, hornblende, and petro-
filex, alternate vertically with primitive limestone, and are so
intermingled as to prove a common origin. But in the Py-
ûnées these bands are furmounted by secondary lime-rove,
replete with marine spoils, and containing even skeletons of
animals, so that he concludes that the highest mountains of
the chain must have yielded to the fury of the ocean, and
that the secondary parts only now exist. Mr. Townsend
(Spain, i. 89.) observes, that the lime-rove and schistus
feed the vegetation on the N. of the Pyrënées, while the S.
is barren, and consists of granite; while, in fact, mountains
are generally barren and precipitous on the S. and W., be-
cause the mott violent rains and tempests come from those
regions. Pinkerton's Geog. vol. i.

The pastures over these mountains from one country to
another are five; the three principal of which are from St.
Sebastian to St. Jean de Luz; from Pamplona to St. Jean
de Luz; and from Jonquera to Perpiñan. These mountains
afford quantities of timber for shipping, which are con-
veyed, by means of the Ebro and other streams to the
sea, with abundance of pitch and tar. The Pyrenées give
name to three of the French departments.

PYRENES, Baiteira, one of the nine departments of the
southern region of France, in N. lat. 42° 40′, formerly
Rouffillon, bounded on the N. by the departments of the
Arrières and the Aude, on the E. by the Mediterranean,
S. and W. by Spain; about 58 miles from E. to W., and
from 18 to 25 from N. to S., or 28 Fr. leagues in length,
and 15 in breadth, containing 4337½ kilometres or 212
square leagues, and 177,674 inhabitants; it is divided into
3 districts, 17 cantons, and 249 communes. The three
districts are Perpiñan, including 31,961 inhabitants, Ceret,
24,705, and Prades, 41,163. According to Halleinfratz,
the number of circles is 3, of canton 27, and of inhabit-
ants 11,415. The contributions in the 11th year of the
French era amounted to 1,010,250 fr. and the expenses for
administration, education, &c. to 181,061 fr. 85 cents.
The capital is Perpiñan. This department is fertile in
corn, wine, oil, flax, hemp, fruits, and pastures. On the
hills there is little wood, but variety of medicinal plants
and herbs. There are several lofty mountains on the S. and
W. boundaries, as Maifane, Canigou, &c.

PYRENES, Lower, a department of France, in the
S.W., or Garonne region, composed of Béarn, Navarre,
Basse-Française, with a part of Chalofi and of Landes,
in N. lat. 43° 10′, and bounded on the N. by the departments
of the Landes and Gers, on the E. by the department of the
Upper Pyrenées, on the S. by Spain, and on the W. by
the sea; 70 miles in length, and from 15 to 45 in breadth, or
16 Fr. leagues in length and 10 in breadth. It contains
8972½ kilometres, or 388 square leagues, and 384,930 in-
habitants. It is divided into 5 districts, 40 cantons, and
660 communes. The districts or circles are, Pau, including
99,486 inhabitants, Oloron, 69,484, Mauléon, 69,447;-
Bayonne, 69,486, and Orthez, 85,127. According to
Halleinfratz, its circles are 6, its cantons 44, and the
number of its inhabitants 138,539. Its capital is Pau. Its
contributions in the 11th year of the French era amounted
to 1,129,950 fr. and its expenses for administration, &c. to
296,140 fr. 65 cents. This department, bounded on one
side by the Pyrénées, and on the other by the ocean, pre-

PYRENOIDES, in Anatomy, a process of the second
dorsal vertebra of the neck; called also odontoides,
desiformis, or the tooth-like processes.

The word pyrenoïdes is formed of πυρενοιδεσ, nucleus, kernel,
or berry, and οις, figure.

PYRETHRUM, in Botany, an ancient Greek name,
dominated by Haller, Gautier, and the writer of the present
article, who are followed by Willdenow and Aiton, for
the genus in question, on account of its resemblance to the
πυρεθρος of Dioscorides. The latter is, however, the An-
themis Pyrethrum of modern writers, or Pellitory of Spain;
owing its Greek appellation to the fiery or pungent flavour
of the root; whence also it obtained the Latin name of Sa-
fraria, because it causes so remarkable a flow of saliva.
Our present Pyrethrum is made up of several Linnaean
species of Chrysanthemum and Matricaria, with some new
ones.—Haller Helvet. v. 1, 400. Sm. Fl. Brit. 690.
Pursh v. 2, 527. Garrit. t. 196.—Clas and order, Syng-
ephia Polygaminus pyrethrum. Nat. Ord. Compound diffige-
Linn. Caryophylles, Jull.

Gen. Ch. Common Calyx hemispherical, imbricated; the
scales close-prefted, rather acute, membranous at the edges.
Cor. compound, radiated. Florets of the disk perfect,
numerous,
PYRETHRUM.

nervous, tubular, funnel-shaped, with five spreading segments; those of the radius more than 12, female, ligulate, elliptic-oblong, three-toothed. **Stam.** in the perfect florets. Filaments five, capillary, very short; anthers united into a cylinder, hardly so long as the corolla. **Pil.** German, in all the florets, obvate, style thread-shaped, longer than the filaments; stigma two, divaricated, abrupt. Peric. none, the calyx remaining unaltered. **Seeds** nearly silex in all the florets, oblong, quadrangular, each crowned with an erect, membranous, more or less lobed border. **Recept.** naked, dotted, convex. Eff. Ch. Receptacle naked. Seeds crowned with a membranous margin. Calyx hemispherical, imbricated with sharpish scales, bordered with a membrane.

Section 1. **Radius white; rarely reddish.**
1. **P. frutescens.** Shrubby Feverfew. Willd. n. 1. (Chrysanthenum frutescens; Linn. Sp. Pl. 125.) Leucanthemum canariense, fopore pyrethrum; Walth. Hort. 31. t. 24. Buphthalmum canariense leucanthemum; Pluk. Alm. 127. Pith. t. 272. f. 6.)—Stem shrubby. Leaves fleshy, pinnatifid, linear, toothed; three-elliptic at the extremities. Native of the Canary Islands, from whence it was brought very early; flowering in the golden-bone most part of the year. The woolly *flora* is much branched. The leaves are crowded about the ends of the branches, and in their fleshy texture, as well as linear forked figure, resemble those of a *Chelidonium*, or *Artemisia*. The flowers are terminal, solitary, on long naked stakes, and resemble a white daisy.

2. **P. simplicifolium.** Simple-leaved West Indian Feverfew. Willd. n. 2. (Matricaria? proflata; Swartz Ind. Occ. v. 3. 136.)—Leaves obvate; toothed at the extremity. Stalks axillary, single-flowered. Branches proflate. Gathered by Von Rohr in Curações and the neighboring islands. It has never been brought alive to Europe. Stem herbaceous, branched, decumbent, round, downy, especially the ends of the branches. Leaves alternate, nearly fleshy, wedge-shaped, obvate, or roundish, half an inch long, downy, ribbed, notched or serrated; mostly accompanied by two minute leaves at the base. Stalks opposite to the leaves, thickish, an inch long, erect, downy, each bearing a yellowish-white, nearly globose, *fiver*, whose disk is entirely yellow. **Seeds** crowned with a quadrangular minute border. **Square.**

3. **P. pannonicum.** Goose-tongue Feverfew. Willd. n. 3. (T. at. n. 2. Leaves linear, finely serrated. Flowers corymbose. —Native of mount Caucasus. Sir Joseph Banks sent it to Kew in 1803. Willdenow describes this as perennial, with the habit of *Achillea Pyrethrum*, only the flowers are twice as large. The *flora* is branched, either erect or decumbent. Leaves an inch long, very finely and sharply serrated. **Corymbs** terminal, simple, the flals flesh-colored. **Radiant flowers ovate.** *Corymb* half the length of the seeds.

4. **P. verum.** Creeping-rooted Feverfew. Willd. n. 4. (Chrystanthenum serotinum; Linn. Sp. Pl. 125.) Jacc. Obst. fac. 4. 8. t. 92. Bellis americana, procumbent, serotina, ramosa, flore amplissima; Pluk. Alm. 125. Pithy t. 272. f. 6. —Leaves lanceolate; the lower ones strongly serrated; the upper entire. **Branches corymbose.** Supposed to be a native of North America; but Michaux has it not. and Pursh merely saw a specimen in Mr. Lumbert's herbarium, probably, like that of Linnaeus, from a garden. The plant was cultivated by Miller, and is a Hardy perennial, flowering in October or later. Its *flora* is herbaceous, two or three feet high, much branched, leafy, furrowed, and angulate. **Leaves** alternate, feafe, two or three inches long, and half an inch wide, entire or sparingly serrated in the upper parts of the stem, but mottly furnished, in our specimen, with a sharp tooth on each side at the base, which we do not find mentioned by authors. The flowers are terminal, solitary, much like our common *Chrysanthenum Leucanthemum*, but rather smaller.

5. **P. alpinum.** Bag Feverfew. Willd. n. 5. Walld. et Rikaib. Hungar.—**Leaves** lanceolate, all deeply serrated. **Stem** erect, branched at the top. —Native of wet ground in Hungary and Spain. Perennial. Very nearly akin to the last, but different in having all the *leaves* deeply serrated throughout, and the *flora* branched at the top only. **Square.**

6. **P. halleri.** Hallerian Feverfew. Willd. n. 6. (P. n. 97; Hall. Helvet. v. 1. 41. Leucanthemum alpinum tenfusilium; Barcel. C. 1. 458. f. 35.)—Stem-leaves lanceolate, deeply toothed; radical ones pinnatifid, on long flals. Seeds single-flowered. —Native of the Swiss alps, in rocky places. The roots are creeping, black, long, and slender, with very long fibres. **Stems** solitary, single, leafy, spreading, three or four inches high. **Leaves** smooth; the lowermost short, wedge-shaped, deeply pinnatifid, on long flals; the uppermost feale, deeply and sharply toothed, an inch or more in length. **Flowers** solitary, forked, terminal, large; the calyx-feales bordered with black; the radiant florets broad and elliptic. The above figure of Barrelier seems to accord better with our Swiss specimens than fig. 2. cited by Haller and his copyists, except that the upper leaves in fig. 3. are too narrow.

7. **P. alpinum.** Alpine Feverfew. Willd. n. 7. (Chrysanthenum alpinum; Linn. Sp. Pl. 125.) Leucanthemum alpinum; Chuf. Hiti. v. 1. 335. —Lower leaves wedge-shaped, pinnatifid; uppermost linear and entire. **Stem** single-flowered. —Native of the German, Swiss and Italian Alps. The creeping roots throw out many short tufted leafy *flores*, each bearing one long simple *flower-flake*, downy in its upper part, and furnished below with one, two, or more, alternate, simple, linear, entire floral leaves. The rest of the *foliage* is flaked, pinnatifid, somewhat pectinate; the segments elliptic, entire, smooth, rather fleshy; each half, with its flat flake, an inch or more in length. **The flower** is large, much like the last.

8. **P. Balfoua.** Collybia-leaved Feverfew. Willd. n. 8. (Chrysanthenum Balfouanum; Linn. Sp. Pl. 125.) Jacc. Obst. fac. 4. 8. t. 89. Leucanthemum orientale, colli hortensis folio; Tourn. Cor. 37. —Leaves ovate-oblong, serrated, auricled. **Flowers** corymbose. —Native of the Levant; rare in our gardens. Mr. Blackburn is said to have cultivated it in his celebrated collection at Orford about 35 years ago. The habit of this species is so much like Common Collybia, that one cannot help suspecting they are mere varieties of each other. The preference of a radius in the plant before us, is known, by the examples of *Bidens* and *Dictyoscyphus*, to be in no infallible distinction. There is indeed the membranous crown of the *flora*, as Willdenow remarks, which makes this a *Pyrethrum*, not a *Chrysanthenum*; but such belongs to *Tanacetum*, and confirms our supposition, or rather our belief, that the present is but a radated variety of the Collybia. The **radius** is about twice the length of the *colo*, white, not yellow, as *Linnaeus* seems to describe it.

9. **P. palescens.** Mars Feverfew. Willd. n. 9. (Leucanthemum orientale, chrysanthenum folio, tanaceti odor; Tourn. Cor. 37.) —Leaves smooth, fleshy, lyrate-pinnatifid. **Stalks** single-flowered, corymbose. —Native of marly places in Armenia. *Tournefort.* —**Stem** erect, furrowed, smooth, two feet high. Leaves an inch or inch and
and half long; their segments lanceolate, toothed at the outer margin, the lower ones deep. The upper gradually confluent into a large cut terminal lobe, and entire. Stalks single-flowered, leafy, alternate, four or five at the top of the stem, composing a corymbus. Flowers the size of Chrysanthemum Leucanthemum Willd.

10. P. pinnatifidum. Pinnatifid Feverfew. Willd. n. 10. — Leaves downy, glaucous, nearly febble, lyrate-pinnatifid, unequally toothed. Flowers corymbose.? — Wilddenow describes this from living specimens, but did not know their native country. The stem is said to be erect, two feet high, branched, furrowed, slightly downy. Leaves downy on both sides, pinnate at the base; pinnatifid in the middle; cut at the end; their length two or three inches; their segments lanceolate, unequally toothed. Corymbs simple, at the tops of the stem and branches. Flowers almost like the common P. Parthenium.

11. P. macrophyllum. Large-leaved Feverfew. Willd. n. 11. Ait. n. 6. (Chrysanthemum macrophyllum; Wald. et Kitai. Hung. v. t. 97. t. 94.) — Leaves hairy, nearly febble, pinnatifid, toothed, obtuse. Corymb terminal, compound. — Native of the woods and mountains of Hungary. Sir J. Banks introduced it in 1803. to the Kew garden, where it is a hardy perennial, flowering in July and August. This plant resembles Achillea macrophylla, for which some botanists have mistaken it, but is much larger. We have seen no specimen.

12. P. rofulum. Rofe coloured Feverfew. Ait. n. 7. Willd. Enum. 905. (Chrysanthemum coccinum; Willd. Sp. Pl. v. 3. 2144.) Sims in Curt. Mag. t. 1850. Euphorblamum orientale, tanacetum folio ampliore, flore magno coccinco; Toun. Cor. 37. Buxb. Cent. v. t. 25. t. 20.) — Leaves smooth, pinnate; leaflets once or twice pinnatifid, serrated, acute, spreading. Stem erect, single-flowered. Gathered by Toumfort in Iberia. It is found also on mount Caucasus, from whence that distinguished collector Mr. Lodigges received seeds of this elegant species in 1803. The plant proves perennial and hardy, flowering in August or September. The stem is 12 to 18 inches high, more or less leafy, bearing one large handlike flower, whose disk is yellow, and the radius of a rich rofe colour, or crimson, on its upper side; sometimes varying to white. The leaves are from two to four inches long, thick, rigid, pale beneath, pinnate, variously serrated, cut or pinnatifid, all the points and furvatures very acute. Toumfort gathered plenty of this plant, and his original specimems are dispersed through many collections.

13. P. corystosum. Mountain Feverfew. Willd. n. 12. Ait. n. 8. (Chrysanthemum corystosum; Jacq. Altr. t. 379. Ch. corybiferum; Linn. Sp. Pl. 1251. Tanacetum non odorum; Ger. Em. 652.) — Leaves pinnate; leaflets lanceolate, pinnatifid, sharply serrated; the upper ones confluent. Flower-flasks corymbose. — Native of mountainous woods in Siberia, and many parts of Germany. Gerard appears, by the catalogue of his garden, to have cultivated it in 1596. The stem is perennial, woody, with long fibres. Stems erect, two or three feet high. Leaves somewhat like Tanty, but without scent or taste, except that after a while, according to Jacquin, they cause a heat or pungency in the mouth. The numerous large white flowers, each with a bright yellow disk, form an ample terminal corymb.

14. P. Parthenium. Common Feverfew. Sm. Fl. Brit. n. 1. Engl. Bot. t. 1231. Willd. n. 13. Ait. n. 9. (Matricaria Parthenium; Linn. Sp. Pl. 1255. Woody Suppl. t. 249. Fl. Dan. t. 674. Matricaria; Ger. Em. 652.) — Leaves pinnate; leaflets oblong, obtuse, pinnatifid and cut. Stem branched. Flowers corymbose. Radius about twice the length of the calyx. Seed-crown toothed. — Native of cultivated or waste ground throughout Europe, springing up abundantly with us in neglected gardens or court-yards, flowering all summer long. The root appears to be rather biennial than perennial. The whole herb is bitter and aromatic, hoary or downy. Stem hoary. Leaves, flat and divided. Flowers numerous, each about the size of a common daily, but with a large yellowish disk, and short white radius. Sometimes the latter is wanting; and more frequently the flowers are double, the disk becoming white and ligulate, like the radius, but each flower of a smaller proportion. The receptacle is flat.

15. P. parthenioides. Narrow Hoary Feverfew. Willd. n. 14. — Leaves pinnate; leaflets oblong, obtuse, pinnatifid, toothed. Stem waxy-like. Flowers corymbose. Radius twice the length of the calyx. Seed-crown entire. — Wilddenow describes this from a garden, without knowing whence it came. He says it is very like the last, but has a taller, waxy-like stem, narrower leaves, a disk but half as large, though the radius is larger, and an entire, hoary-topped, margin to the seed. A plant now becomes a weed in Kew garden, and first to have been imported from China, answers precisely to this description in every point, except that its stem is scarcely less hoary than in P. Parthenium. We are persuaded, nevertheless, that it is what Wilddenow meant. Its leaves are conspicuously hoary, with narrower divisions than those of the last, and the flowers, on account of their long and brilliant-white radius, are more striking. We have had no opportunity of investigating the crown of the seed.

17. P. fuscatum. Dinghy Feverfew. Willd. n. 16. Sm. Prod. Fl. Grce. Sibth. n. 2095. (Chrysanthemum fuscatum; Desfont. Atlant. v. 2. 237.) — Leaves downy, pinnate; leaflets with a few deep linear-oblong segments. Stem branched from the base, diffuse. — Gathered by Desfontaines in uncultivated fields near Tunis. Sibthorp found it in Greece. The root appears to be perennial, bearing many widely-spread or procumbent stems, a half long, which are leafy, and slightly branched. The leaves are rather succulent. Flowers terminal, solitary, large, with a blackish calyx, pale yellow disk, becoming brown in decay, and broad white elliptical radiant florets. It blossoms in winter.

18. P. inodorum. Corn Feverfew, or Scentsleaf Mayweed. Sm. Fl. Brit. n. 2. Engl. Bot. t. 676. Willd. n. 17. Ait. n. 11. (Chrysanthemum inodorum; Linn. Sp. Pl. 1253. Fl. Dan. t. 696.) — Leaves pinnate, in many capillary segments. Stem branched, spreading. Seed-crown entire. — Found in fields and waste ground throughout most parts of Europe, especially where the soil is gravelly, flowering in autumn. Root tapering, annual. Herb almost without any peculiar scent, by which it is readily known, in every state of growth, from Anthemis Cotula. The stem is a foot or more in height, widely spreading, clothed with pale-green smooth leaves, whole leaflets are deeply and variously divided into linear, almott capillary, pointed segments. More simple segments are numerously
PYRETHRUM.

numerosely crowded about the bottom of each leaf, rendering it in a manner, lyraste, and surrounding the stem or branch. Branches somewhat corymbose, each terminated by a rather large flower, with long white rays, and a prominent yellow disk. The late Mr. Crowe once found in Norfolk a partly double-flowered variety.

10. P. maritimum. Sea Feverfew. Sm. Fl. Brit. n. 3. Eng. Bot. t. 979. Willd. n. 18. Ait. n. 12. (Mariana maritima; Linn. Sp. Pl. 1256. Chamaeleum maritimum). Bearberry, chief of all herbs, is his brevissimi officine virentibus; Dill. in Rau Syn. 186. t. 7. f. 1.)—Leaves double pinnate; segments linear, pointed, almost convex above; keeled beneath. Stem diffuse. Seed-crown lobed.—Native of the sea-coast in the north of Europe. Found in several parts of Scotland, as well as on the south coast of England, and in Lancashire and Durham, flowering in July and August. The root is perennial. Stems numerous, profusely spraying circularly to the extent of two or three feet. The leaves are more flaky than in the foregoing; the disk of the flower broader, in proportion to the length of the rays; and the crown of the disk divided into three or four lobes. The whole herb is slightly aromatic, and of a darker more flaming green than inodorum.

20. P. parviflora. Small-flowered Feverfew. Willd. n. 19. — "Leaves doubly pinnate; leaflets linear-thread-shaped, in two or three deep divisions. Stem erect, branched. Seed-crown two-lobed."—Described by Willdenow from living specimens, but the native country of this species is unknown. It is said to be annual, greatly resembling P. inodorum, but having a taller and upright stem; a shorter radius; and a green two-lobed crown to the seed.

Section 2. Radius yellow.

21. P. multicaule. Many-talked yellow Feverfew. Willd. n. 20. (Chrysanthenum multicaule; Desfont. Atlant. v. 2. 182. t. 256.)—Leaves simple, smooth, flatulate, the lower ones toothed. Stem erect, much branched from the bottom. Native of sandy hills near Mafcar, in Barbary. Root fibrous, apparently annual. Stem branched from the base principally, bushy; the branches naked above, each bearing a solitary flower, about as big as a French Marygold, whose radiant florets are yellow, and of a very broad elliptical form, about eight or nine number.

22. P. trifurcatum. Three-forked Yellow Feverfew. Willd. n. 21. (Chrysanthenum trifurcatum; Desfont. Atlant. v. 2. 251. t. 255. f. 2.)—Leaves flaky, smooth, linear, acute; the lowermost pinnate; uppermost univalved. Stem ascending, single-flowered. Native of fields near Kerwan in Barbary, flowering in winter. The stem is flaky, a foot high; leafy below; naked above; terminated by a very large flower, with numerous yellow radiant florets. Some leaves are partly bipinnate; others threecleft; the uppermost flaky; all linear, wavy, acute, and of equal breadth. Branches.

"Root many-headed, woody. Stems several, simple, a span high, linear-flowered. Leaves hoary; the radical ones flaked, oblong, fading when arrived at maturity, and altogether wanting when the flowers open; lower stem-leaves flaked, pinnate at the extremity, with three or four pair of very short linear-awl-shaped leaflets, and a membranous linear footstalk; the upper one linear, pinnate, and entire. Rays of the corolla pale yellow. It resembles Chrysanthemum pectinatum, but differs abundantly in the calyx not being membranous, and in having a crown to the flower."

We know nothing of Afo's plant. Willdenow cites an additional synonym, Bareuther's t. 1132. f. 1, which seems to have no affinity to the figure of Boccone, and much more resembles Cineraria minuta. Cavall. Ic. t. 35. f. 1, under which indeed Willdenow likewise quotes it, Sp. Pl. v. 3. 2868.

24. P. orientale. Oriental Yellow Feverfew. Willd. n. 23.—"Leaves doubly pinnate; leaflets linear, stems ascending, single-flowered."—Native of Georgia. Stems six inches high, naked above. Lower leaves an inch long; the upper ones half as long, and only simply pinnate. Scales of the calyx withered at the edge. Flower deep yellow, the disc of Chrysanthemum ficatum. Willd.

25. P. millesfolium. Milfoil-leaved Yellow Feverfew. Willd. n. 24. Ait. n. 13. (Pn. 172; Gmel. Sib. v. 2. 207. f. 186. f. 1. Chrysanthenum millesfolium; Linn. Syn. Vég. ed. 13. 624. Anchusa milletolia; Linn. Sp. Pl. 1263. Achillea folis pinnatis, &c.; Mill. Ic. t. 9.)—Leaves doubly pinnatifid, linear, blunth. Stem corymbose. Rays half as long as the diameter of the disk.—Native of Siberia. A hardy perennial, flowering throughout the summer. The leaf is twelve or eighteen inches high, leafy, branched and corymbose, bearing eight or more long-flaked yellow flowers, whose disk is about half an inch in diameter, and their radiant florets of a short roundish figure, hardly extending a quarter of an inch from the disk. Seed-crown toothed. Leaves double and interruptedly pinnatifid, with linear, blunter segments, each tipped with a minute point; their surfaces both downy, or somewhat silky. The leaves, as well as flowers and seeds, are very distinct from Chrysanthemum italicum, to which Linnaeus compares this species.

26. P. bipinnatum. Wing-leaved Yellow Feverfew. Willd. n. 25. Ait. n. 14. (Pn. 172; Gmel. Sib. v. 2. 207. f. 85. f. 1. Chrysanthenum bipinnatum; Linn. Sp. Pl. 1255.)—Leaves doubly or triply pinnatifid; their segments dilated upwards, minutely pointed. Stem nearly simple. Rays wedge-shaped, not a quarter so long as the diameter of the disk.—Native of Siberia, flowering in June. Introduced at Kew by Dr. Fitch, in 1746. This differs from the half in having more compound leaves, whose ultimate segments are almost elliptical, and all their points distinctly awned. But the flowers especially differ in being fewer, from one to three on each stem, and furnished with a disk near an inch wide, while their radiant marginal florets are short, broad, and wedge-shaped, with broad spreading teeth. The calyx, as well as all the herbage, is hoary with soft hairs.

27. P. indicum. East Indian Yellow Feverfew. Sims in Curt. Mag. t. 1521. Ait. n. 15.—Leaves pinnatifid; their segments dilated upwards, lobed. Stem branched. Flowers on long stalks, nearly globular. Radiant florets few, very short. Sent by Dr. Roxburgh, from the East Indies, to A. B. Lambert, 1769. It proves a hardy annual in our gardens, flowering most part of the summer. The stem is much branched, but the pinnatifid, though more simple and broader, leaves, betray an affinity to the two last species, which is confirmed by the short yellow radiant florets. These however are, according to Dr. Sims, more generally wanting. The flowers are solitary, on long swelling furnished stalks, terminating each branch; their disk nearly an inch wide, and finely convex. The herbage appears to be smooth.

28. P.
28. P. Myconi. Tongue-leaved Yellow Feverfew. (Chrysanthemum Myconi; Dalech. Hist. 873. Linn. Sp. Pl. 1254. Wild. Sp. Pl. v. 3. 2148. Ant. Hort. Kew. v. 5. 96. Jacq. Obl. fac. 4. 10. t. 94.)—Leaves tongue-shaped, obtuse, toothed, clasping the much-branched stem. Radiant florets numerous, roundish. —Native of fields in the south of Europe; a hardy annual with us, but preferred for the sake of variety, rather than ornament, the flowers being inferior in size and splendour to our wild Chrysanthemum segetum, while the leaves resemble those of C. Lunetorum. The plant however is very different from both these, and a true P. Myconi, akin to the last described, the seed having a very evident membranous crown, as Willdenow, Sp. Plan. Linnaeus, mentions; yet he still left this species where he found it. Our predecessor, the excellent Mr. Wood, has corrected this error. (See Chrysanthemum, at the end.) We venture likewise to correct the specific name, which authors have copied incorrectly from Dalechamp. He calls the plant Mycon, after its discoverer Myconius. The stem is very much branched. Leaves simple, an inch and a half or two inches long, smooth. Flowers long on long solitary stalks, at the ends of the branches, bright yellow, an inch wide; their radiant florets numerous, crowded, short, of a roundish or oblong shape. Seed-crown large, jagged, and fringed.

PYREXIA, formed from πυρ, fire, and εξαιρετικον, of εκ, out, of ειρατικον, medicines good against fevers.

PYREXIA, in Medicina, from πυρ, fire, a term used by Dr. Cullen to signify feverish action generally, whether idiopathic or sympathetic. The same writer also used the term as the denomination of his first clas of diseases, including fevers and inflammations. See his Nofol. Method. clas 1, Pyrexia.

PYRGUS, or PYRGI, in Ancient Geography, a town of Italy, upon the coast of Etruria; placed by Ptolemy between Cafrum Novum and Alsum, and said by Livy to have been a Roman colony. —Allo, a town of the Peloponnese, in Messenia.

PYRGO, in Geography, a sea-port town on the S.E. coast of the island of Santoria. N. lat. 36° 26'. E. long. 25° 58'.

PYRUS, among the Romans, a dice-box of the shape of a modius, open above, and having a great many shelves or partitions within it; so that when the dice were thrown into it out of the fritillum, they were thereby overturned many times before they could reach the bottom, in which there was an opening for them to fall through upon the table.

PYRUS, in Botany, a genus of Locoweo's, Fl. Cochinch. 120, which Mr. Brown, Prod. Nov. Holl. v. 1. 533, reduces to Arbacia, see that article. The name is taken from πυρ, a fire, alluding to the conical shape assumed by the converging flames.

PYRHOPOEOCEILOS, in the Natural History of the Ancients, a stone called from its having a great many spots of the colour of fire.

PYRIATERION, a word used by the ancients to express a sweating room.

PYRIATOS, a word used by some authors to express a brick when heated, in order to be applied to the body wrapped up in a cloth by way of a dry fomentation.

PYRICAUSTUM, a word used by medical writers to express a burn or scald.

PYRICUBIUM, in Natural History, the name of a genus of fossil bodies, usually comprehended, with many others of very different figure and structure, under the general name pyrites.

PYRIFORMIS, in Anatomy, a muscle of the thigh, flattened and triangular in its figure, situated at the back of the pelvis, and extending from the facrum to the great trochanter. The posterior surface is covered by the gluteus magnus, and partly by the ilidus. The anterior is partly in the pelvis, partly on the outside of the cavity. Within the pelvis it corresponds to the rectum, the faciaculus, and the hypogastric vessels: externally to the cavity it covers the gluteus minimus, the os innominatum, and the capsule of the hip. The upper edge corresponds to the faciaculus notch, and the gluteus artery; it then lies close to the gluteus medius. The inferior edge corresponds to the lesser faciaculus ligament, and then is parallel to the femur superior; it is at first separated from the latter muscle by the great sciatic nerve, and afterwards approaches to, and is united with it.

The basis of the pyriformis is attached to the side of the anterior surface of the facrum, in the intervals of the sciatic foramina, to thee foramina of their outer parts, to the anterior surface of the great faciaculus ligament, and to the pollicus and upper part of the os innominatum. The muscle proceeds from within outwards, and rather downwards, paffes out of the pelvis at the great faciaculus foramen, gradually diminishes, and terminates in a small tendon, fixed to the upper part of the intemal surface of the great trochanter.

The attachment of this muscle to the great trochanter is by means of a tendon, the lower edge of which is connected to that of the superior giminus. This tendon expands into an aponeurosis, which, after extending on the front of the muscle, enters into its substance. The fleshy fibres arise from the parts mentioned above; and are fixed in all directions to the tendon. Sometimes a portion of the sciatic nerve passes through a slit in the muscle.

When the thigh is extended, the pyriformis will rotate it outwards; but when it is bent, it will act as an abductor. If the thigh is fixed, it will move the pelvis in an opposite direction.

PYRIPLEGES, a word used by the old writers in medicine to express a person labouring under an extreme degree of a febrile heat.

PYRIPACIS, in Natural History, the name of a genus of pyrites, the characters of which are these: they are compound, inflammable, metallic bodies, found in loose detached masses of a simple and uniform, not iterated internal structure, and are covered with an invelent coat or crust.

Of this genus of fossils there are three known species. Hill.

PYRIPOLYGONUM, the name of a genus of fossils, the characters of which are, that they are compound metallic bodies, of a regular figure, consisting of twelve planes.

There is only one known species of this genus, though subject to great varieties in its appearance; and this has been by authors hitherto confounded with many other bodies of a very different nature and figure, under the general name pyrites.

It is not unfrequent in Cornwall and Devonshire; but is much more common in Germany. Hill.

PYRITES, Sulphur metallic, in Mineralogy and Chemistry, a name given to certain ores which contain a large quantity of sulphur, and have a metallic lustre. The Greek word
PYRITES.

The word πυρίτης, formed of πῦρ, fire, denotes fire-iron; a denomination given to this substance on account of its inflammability. For the mineralogical characters of copper pyrites, and iron pyrites, see Copper Ore, and Iron Ore.

Before there are any pyrites, auriferous pyrites, and true pyrites. Combinations of sulphur with the metals are called by chemists sulpharates; and the different kinds of pyrites are properly metallic sulpharates. Sulphur has a great affinity for iron, and in combination with this metal, under the form of pyrites, exists in extensive beds in primary mountains, or is disseminated through the secondary rocks and strata, in veins and marls, or variously crystallized: it occurs also in beds of coal and bituminous clay. Iron pyrites may be considered, after the earths, as one of the most abundant substances in the mineral kingdom, forming a constituent part of the globe, and by its decomposition giving rise to many important subterranean phenomena.

The proportions of iron and sulphur in the different sub-species of iron pyrites enumerated by mineralogists are,

- 52 to 54 Sulphur
- 48 to 56 Iron.

Magnetic pyrites differs from common pyrites: its constituent parts, according to Mr. Hatchett, are,

- 36.50 Sulphur
- 63.50 Iron.

By the application of heat common pyrites becomes susceptible of attraction by the magnet; the excess of sulphur being expelled. Iron pyrites is not worked as an ore of iron, but is principally valued for the green vitriol or sulphate of iron, which it affords when exposed to air and moisture. Sulphur may also be obtained from pyrites when heated with charcoal.

The decomposition of pyrites is effected spontaneously by the absorption of oxygen from water and the atmosphere, which converts the sulphur into sulphuric acid, and the iron into an oxide. These substances unite during the process, and form the sulphate of iron, or green vitriol.

Some kinds of pyrites are rapidly decomposed, others require to have part of the sulphur expelled by heat. The pyrites, or pyritic substance intended to form vitriol, is collected in extensive heaps, spreading the surface as much as can be conveniently done. The ground over which these heaps are spread should be impervious to water, and inclined, in order that the saline matter which effloresces may be washed off, and conveyed into reservoirs to crystallize. As the decomposition proceeds the mafs becomes heated, and is occasionallv moistened, particularly when the air is dry and warm. These beds continue productive for many years, and if the pyrites be pure, but little residue is left. An excess of sulphuric acid is formed during the process, on which account a quantity of old iron is added to the solution, to saturate it, and obtain the salt in a crystallized state. During the decomposition of pyrites much heat is evolved, and a considerable absorption of oxygen from the atmosphere takes place. The fact was first observed by Henkel, who affirmed, in his "Pyritologia," that air was necessary to the process of vitrification, and that it enters into combination with pyrites and remains fixed in it: "non ut instrumentum transietis sed immersus." This may be considered as a happy anticipation of one of the most important doctrines of modern chemistry. Some geologists have supposed that subterranean fires, and the temperature of hot springs, are occasioned by the spontaneous decomposition of immense beds of pyrites in the interior of the earth, and an experiment made by Lemery gives some plausibility to this opinion. He found that a mixture of iron filings and sulphur, moistened with a small quantity of water, becomes hot in a few hours, the mafs swells, and the parts adhere together; it then breaks with a perceptible noise and crackling, and emits aqueous vapour, and a fetid odour like that of sulphurated hydrogen gas. If the mixture be made in a large quantity, it takes fire in twenty-four or thirty hours. As soon as the emission of aqueous vapour has ceased, the heat becomes greater and greater, is succeeded by inflammation, the smell is then much stronger, and appears to arise from the hydrogen produced by the decomposition of water. Beaumé, who observed this phenomenon from a mixture of one hundred pounds of iron filings, with an equal quantity of sulphur in powder, states that the flames rose to a foot in height, but did not continue longer than two or three minutes; the mafs, however, remained red-hot for forty hours. Lemery the elder gave to this experiment the name of the artificial volcano.

Dr. Watson, in his Chemical Essays, vol. i. p. 187, says that he has repeated this experiment more than once. When made in the open air the flame is of short duration, and the whole mafs; after the extinction of the flame, continues at intervals to throw out spurs. A ladle full of the ignited mafs being dropped down from a considerable height, defended like a shower of red-hot ashes. The effect of this experiment depends on a due proportion of water. Half a pound of flower of sulphur, with half a pound of clean iron filings, mixed with fourteen ounces of water, and worked into a pate, will acquire heat enough to make the mafs take fire.

Some dark-coloured carbonaceous and bituminous earths contain pyrites in minute grains, and decompose with great rapidity when exposed to moisture. In the month of August 1751, the cliffs near Charmouth, in Dorsetshire, containing a similar kind of pyritic earth, took fire in consequence of a heavy fall of rain after a hot dry season, and continued at intervals to emit flame for several years. Almost all kinds of pit-coal in England contain more or less pyrites; in some the quantity is very inconsiderable, in others it amounts so much as to render them unfit for domestic purposes, and totally inapplicable for forges or iron works, on account of the sulphur which they emit when burned. This pyritic coal may be distinguished by its greater specific gravity, and the braff-like metallic appearance of the pyrites with which it is intermixed. Pyritic coal and coal dust, or bituminous clay, containing pyrites, frequently take fire spontaneously in coal mines, or when exposed in heaps out of the pits, and continue burning many years. Instances of this kind now exist in the north of England; and so intense is the heat produced by the ignition of these mafs, that the coal dust is sometimes fulled. We have seen specimens from these heaps which have all the characters of cellular volcanic lava. In the vicinity of Leeds there is a large heap of coal dust which has been on fire nearly half a century; it is covered in parts with vegetation, and presents no appearance of ignition during the day; but if a dry stick be thrust into it the surface is changed in a few minutes. In some of the coal mines in Leicestershire, near Ashby de la Zouch, the stratum of indurated clay over the main bed of coal contains so much pyritic matter, and is so subject to spontaneous inflammation when it falls down and is intermixed with small coal and moisture, that the miners are obliged to close up the space with brick-clay where the coal has been worked, to prevent the access of air to the combustible matter. In this state, excluded from the air, the pyritic earth sometimes becomes ignited, as is evident by the heat communicated to the neighbouring parts of the mine; but the fire is prevented from spreading among the coal,
coal, by the precautionary measure of closing the cavities with clay.

The great heat evolved during the decomposition of pyrites, may proceed in part from the combination of oxygen with the sulphur and iron, and may be increased by the different capacity of the new compound for heat. Whenever chemical changes take place rapidly, they produce a change in the temperature of substances, as in the well-known infusions of lime and water, nitric acid and vegetable oils, &c.

The phenomena accompanying the mud volcanoes in various parts of the world, present many appearances which give probability to the opinion, that they proceed from the decomposition of pyritic flints. See Volcano.

The formation of alum is also effected naturally, in many situations, by the decomposition of pyrites, the sulphuric acid combining with the alumine of pyritic clay. This is not unfrequently the case in excavations of coal mines that have been long worked out.

At Hartlet, near Glasgow, in the excavations of an old coal mine that has been worked for some centuries, there is a very extensive formation of alum, from the decomposition of the roof of the pit. It is a pyritic clay ten inches thick. In the old workings of the mine which are dry the air circulates slowly, and the roof gradually decomposes and exfoliates, and falls upon the floor, in which situation the decomposition proceeds, and the substance assumes the appearance of a peculiar efflorescence. In time the whole space to the roof is filled; it is then removed. The mafs consist of earth richly impregnated with sulphate of alumine, sulphate of iron, and in some infusions with sulphate of magnesia. The coal in this mine, contrary to the usual practice, is worked to the dip, so that the old workings are always dry. To this circumstance may principally be attributed the great accumulation of alum in this mine. In many of the mines in England a similar formation of alum would take place, but they contain too much water to permit the saline substances to remain. In general, alum rock or alum shale require to be exposed in heaps, and burned in the open air, to expel the sulphur, and combine it with the oxygen from the atmosphere. The sulphuric acid thus formed unites with a requisite portion of the clay during the process.

The gypsum, or the sulphate of lime which occurs in beds, among secondary flints or red sand-stone and beds of marle, probably owe its present state to mafs of pyrites, which have exfoliated over common lime-stone, and been decomposed naturally. The sulphuric acid thus produced would unite with the lime, and form gypsum. The great quantity of the red oxyd of iron which is in the flint and marle that accompany this kind of gypsum, gives much probability to this opinion. The crysals of gypsum or selenite found detached in beds of clay had probably a similar origin.

Sulphuret of iron may be formed by heating together iron filings and sulphur. From the experiments of Vanquelin it is proved that there are four sulphures of iron, according to the degree of heat and other circumstances under which the combination may be formed. The first sulphuret consists of

\[
\begin{align*}
73 & \text{ Iron} \\
22 & \text{ Sulphur} \\
\end{align*}
\]

Artificial.

The second sulphuret, of

\[
\begin{align*}
64 & \text{ Iron} \\
36 & \text{ Sulphur} \\
\end{align*}
\]

Natural magnetic pyrites.

The third sulphuret, of

\[
\begin{align*}
54.16 & \text{ Iron} \\
45.84 & \text{ Sulphur} \\
\end{align*}
\]

Artificial.

The fourth sulphuret, of

\[
\begin{align*}
47 & \text{ Iron} \\
33 & \text{ Sulphur} \\
\end{align*}
\]

Natural common pyrites.

When the quantity of sulphur does not exceed 40 per cent., pyrites is soluble in muriatic acid, and may be rendered permanently magnetic. The specific gravity of common pyrites is from 4.6 to 4.83. Of magnetic pyrites 4.5-1.

Arsenic pyrites, called maracite, is distinguished from iron pyrites by its colour, which is a silver white, and by yielding a smell like garlic when rubbed or exposed to heat. See Arsenic Ores.

Auriferous pyrites, or iron pyrites, with a small alloy of gold: the richest specimens of this ore in Europe are found in Transylvania, containing from 0.02 to 0.03 of gold. These ores are distinguished from iron and copper pyrites by their colour, malleability, and specific gravity.

The pyrites, See Tin Ores.

The pyrites, in substance, are never used medicinally; nevertheless, in their products they are very important. From these common sulphur is extracted, in Sweden and Saxony; the native vitriols are produced in caverns of the earth, or on its surface; the greatest quantities of artificial vitriol are prepared; and the mineral waters, vitriolic, aluminous, sulphureous, hot or cold, are supposed to receive their impregnation.

When the matter of the pyrites is mixed with the lead ores, the method of separating the metal by alloying is this: roast two centners of the ore, as in the usual method, and keep a stronger fire than when the ore is pure. The pyrites, especially when it is merely iron, hinder the ore from easily growing clammy or turning into large lumps, or entirely melting. When the ore is sufficiently Walsh, let it cool, beat it to powder, and repeat the roasting to a third fire, till when it is red-hot in the fire, there is no smell of sulphur; then mix the ore with fix centners of the black flux, and two of sandier, and finish the work in the common way, only making the fire greater, and continuing it longer, toward the end of the operation. Cramer's Art of Alloying, p. 292. See Lead Ores.

Pyrites is applied by some authors to the maracite ores of all metals; the names of which are varied according to the metals they partake of.

Thus Pyrites is that of gold; arsenicus that of silver; selenite that of iron; chalcite that of copper; and molybdenite that of lead, &c.

PYRITICUM LIQUAMEN. See Liquamen Pyriticum.

PYRITRICHIPHYLUM, in Natural History, the name of a genus of fossils of the chalk of the pyrites, the characters of which are these: they are compound, inflammable, metallic bodies, found in looklike mafs not of any regularly angular figure, and of a frizzled texture, with foliaceous ends to the frizz, appearing on the surface, or within the mafs.

Of this genus there are only two known species: one having the foliaceous ends of the frizz on the external surface of the mafs; and the other having a smooth external surface, and the foliaceous ends of the frizz covering the sides of internal hollows.

The first of these is found in many of the English and German mines; the other has been yet only found in the mines on Mendip hills in Somersetshire, but there in considerable plenty. Hill.

PYRITRICHUM, the name of a genus of pyrites, the characters of which are these: they are compound, inflammable, metallic fossils, always found in detached mafs of
PYR

no regularly angular figure, and of a simply fratured internal structure.

Of this genus of pyrite there are three known species. All the three species are found plentifully in different parts of the kingdom: the first in all sorts of strata, and often loose on the ground; the second principally in the chalk-pits of Kent and Suffex; and the last in Effex and Hampshire, and very frequently in the German mines. Hill.

PYRTIZ, in Geography. See Purtitz.

PYRONT, a town of Germany, and capital of the country so named; its cathedral is fortified with a broad ditch, high ramparts, and subterraneous passages and vaults; 12 miles S.W. of Hanau. Lat. 51° 57'. Long. 9° 17'.

Alto, a county and principality of Germany, bounded on the N. by the principality of Calenberg, on the E. by Wolfenbuttle and Calenberg, on the S. by Wolfenbuttle, and on the W. by the county of Lippe; about nine miles long, and three broad. The revenues are estimated at 30,000 rix-dollars, principally arising from the springs and salt-works.

PYRONT Water, in Physiology and Medicine, a very brisk, spiritual chalybeate, abounding in fixed air, and which, when taken up from the fountain at Pyrond, in Germany, whences its name, sparkles like the brisket Champaign wine. It has a pleasant, visous taste, and somewhat sulphureous smell. It is perfectly clear, and bears carriage better than the Spa water.

The history of these waters is accurately given by Hoffmann in his observations on them, both in their natural state, and in mixture with other bodies.

He first observes, that they contain a volatile and subtile principle, much more penetrating and strong, as well as in larger quantity, than any other mineral water; but that this is not to be expected in them any where but upon the spot, for those who transport them to other places are constrained to let a part of this fly off, to preserve the rest. If either glass or earthen vessels be filled at the spring, and immediately corked and fastened down, the consequence is, that they will burst on the first motion, or heat of the weather. They are, therefore, forced to fill them only in part at first, and let them stand awhile for this subtile spirit to exhale; and then after the filling them up, to cork and fit them for carriage.

2. If they are drank upon the spot in a morning, on an empty stomach, they affect the nose with a pungent tingling, and disturb the head for many hours afterwards.

3. If they are taken at the spring, they purge but very little; but if taken in another place, after transportation, they purge considerably more, and render the stool black. It is observably also, that if they are left in an open vessel a few days, their virtue wholly exhausts, and they no longer purge nor render the stool black.

4. If tea-leaves, balsam-flowers, or galls, are put into this water, they first change it to a blue, from that to a purple, and finally to a black. This is a ready proof that black is only a deep purple, and purple only a deep blue: a little spirit of vitriol added to this liquor detrays all the colour, and renders it impid as before.

5. If any acid be mixed with Pyrant water, there is raised an effervescence, and bubbles of air are carried up in great quantity; and this whether the stronger acids, such as spirit of vitriol, or aqua fortis, be used; or the weaker, as vinegar, lemon juice, or Rhumt wine.

6. If an alkaline liquor be added, whether it be volatile, as the spirit of sal ammoniac, or fixed, as the oil of tartar, there is no effusion raised, but the liquor becomes turbid and milky. If spirit of vitriol be afterwards added to this, to saturate the additional alkali, the liquor becomes limpid again.

7. Cow's milk mixed in equal quantity with Pyrond water does not coagulate, but, on the contrary, becomes thinner than before, and is preferred from turning four to soon as it otherwise would in hot weather. This is a proof that there is no predominating acid in these waters.

8. If syrup of violets be added to Pyrond water, it turns it to a beautiful green. This is a proof of the alkaline nature of these waters; and it is further proved, by adding spirit of vitriol, or any other acid, to this green liquor, which on that becomes limpid again.

9. Four pints of this water evaporated over a gentle fire, yield no more than two scruples of a dry residuum. Oil of vitriol being poured on this, an acid effervescence arises, and with it an acid and pungent vapour, like that produced by mixing oil of vitriol and common salt. If spirit of vitriol be used instead of the oil, the effervescence is in a less degree, and the falt is in part changed to a bitter saline mias, the remainder separated from which proves to be a calcareous earth, no longer fermenting with the spirit of vitriol.

10. If a quantity of Pyrond water be exposed twenty-four hours to the open air in a hau ton, it will at the end be found to have lost all its virtues, tainting wholly inipid, and being turbid, instead of the fine cleanairs it had before, and a yellow ochrous earth is precipitated to the bottom: after this the liquor will no longer shew any of those qualities, which were before its distinguing characters; it will no longer ferment with acids, nor turn black with galls, nor green with syrup of violets.

It appears from the whole, that the Pyrond waters poffefs a pure, extremely penetrating, and cletic mineral spirit, and that in a very large proportion; and to this their virtues are principally to be attributed. This mineral spirit, while it remains engaged in a calcareous earth, imitates the properties of an alkaline substance; and when joined with a subtile mortal earth, it emulates the properties of vitriol, giving the foulds a black colour, and turning a tincture of galls into ink: and while this remains in the water in these forms of an alkaline or vitriolic principle of so great subtillity, it cannot but give them very great virtues in [illegible]slovenly the tone of the vificera, opening obstructions, and imitating in a proper manner the excretory ducts, so as to make them duly perform their office; but as soon as by the flanding of the water open, or by any other accident, this subtile element is evaporated, all the virtues of the water must be gone with it.

The great quantity of this powerful spirit contained in the waters, makes them more fit for the robust and strong constitutions, when deprived by infirmities, than for the weak and tender ones; but even the tenderest people may take them, only observing to take but a small dose, or to dilute them with an equal quantity of common water immediately before the taking them.

Hoffmann also recommends the Pyrond water mixed with equal quantities of milk, on his own experience, in scurbutic and gouty cases. Hoff. Oper. tom. v. p. 143.

We have already observed, under the articles ACIDULi and CARBONIC Acid, that Pyrond water, and other mineral waters of a similar nature, owe their acidulous taint and peculiar virtues to the fixed AIR (carbone acid) which they contain; and to these articles the reader is referred for a brief history of
PYRMONT WATER.

of this important discovery. We shall here add some farther remarks on the effects and medical uses of this water.

Persons who drink it at the well are affected with a kind of giddiness or intoxication, which is probably owing to the great quantity of carbonic acid with which the water abounds. The common operation of this water is by urine; but it is also a gentle medicament; and if taken in large quantity, proves laxative. However, in order to this effect, it is usual to mix some salts with the first glasses. It is drank by glasses in the morning, to the quantity of from one to five or six pints; according to circumstances; those who drink it walking about between each glass. This water is recommended in fevers where the constitution is relaxed; in want of appetite and digestion; weakness of the stomach, and heartburn; the green sickness; female obstructions and barrenness; the scurvy, and cutaneous diseases; and in the gout, especially, as Hofmann observes, when mixed with milk; in colics; bloody fluxes; disorders of the breath and lungs; in which case it is best taken lukewarm: in nervous, hysteric, and hysterochondrial disorders; in apoplexies and palfies; in the gravel and urinary obstructions; in smallness of the blood; and in obstructions of the finer vessels. It amends the lax tenure of the blood; exhilarates the spirits without inflaming, as vinous liquors are apt to do; and is reckoned among the best restoratives in decayed and broken constitutions. It is said to possess the general virtues of the Spa water, and at the fountain it is more spirited, as well as a stronger chalybeate. Elliot's Medicinal Virtues, &c. of Mineral Waters, 1784, p. 181.

Near the famous well at Pyrmont is a lime quarry under ground, from some parts in which a fulnureous fluid comes out, which commonly rises to a small height. Animals held in this terra are soon suffocated, but recover, if quickly taken out. When a man stands in this terra, but with his head over it, it proves an excellent medicament. Dr. Scip proposes to perform cures in several diseases with it. See Phil. Trans. N° 448, sect. 4, and Mifc. Berolin. tom. v. part 2. sect. 4. See Grotta del Serpi.

PYRMONT Water, Imitation Of. This medicinal water may be imitated very nicely by art in the following manner: take a quart of the purest and lightest water, add to it thirty drops of a strong solution of iron made in spirit of salt, a drachm of oil of tartar per diem, and thirty drops of spirit of vitriol, or a little more or less, as is found necessary, not to let the alkali of the oil of tartar prevail too strongly, though it must prevail a little. Shake all briskly together, and on standing it will be found extremely to resemble the true Pyrmont water.

The bulbs on which this is founded is the analysis and trial of the true Pyrmont water, by which it is found to contain a subtle aqueous fluid, a volatile iron, and a predominant alkali, all joined together into one bril:k pungent spirittuous water. The artificial Pyrmont thus made, if the proportions are carefully mixed, will extremely resemble the natural, and will have the same effect as a medicine. Shaw's Lectures, p. 96.

But the best method of forming artificial Pyrmont water is by impregnating it with fixed air, or carbonic acid, for which we are indebted to Dr. Prieley. The first person, we believe, who actually compounded an artificial spirituous or spirittuous water, like that of Beltz or Pyrmont, was M. Venel; though he was ignorant of the real nature of the ingredient to which it owed these qualities, and which he erroneously supposed to be common air. For this purpose he diffused in a part of water two draams of foddle alkali, to which he added an equal quantity of marine acid; in the process he made use of a vessel with a narrow neck, and to prevent the escape of the air, he disposed the ingredients in such a manner, that they could not communicate with each other till after the bottle was corked. In this case the fixed air diffused from the alkaline fluid, in a phial nearly full and closely corked, being confined, fudders a degree of compreccion that greatly promotes its combination with the water. See Memoires presented par les Savans Etrangers, tom. ii. containing two Memoirs of M. Venel, read before the Royal Academy of Sciences in 1759; and Lavolier's Experiments, &c. p. 24, &c. However, Dr. Prieley was undoubtedly the first who so far improved upon the discoveries made by himself and others in relation to the principle then denominated fixed air, as to contrive an easy method of impregnating water with it. The first idea of this kind occurred to him in 1757, when, having placed shallow velettes of water within the region of fixed air on the surface of the fermenting velettes of a brewery, and left them all night in that situation, he found that the water had acquired a very feebile and pleasant impregnation. He proceeded to accelerate the impregnation by pouring the water from one velette into another, while they were both held within the sphere of the fixed air. The method of effecting this by air diffused from chalk and other calcareous substances, did not occur to him till the year 1772, when he published his directions for this purpose, together with a drawing of the necessary apparatus, which he had before communicated to the Board of Admiralty. This apparatus, represented in Plate XV. Pneumatics, fig. 1, consists of a glasse ¥, with a narrow neck, and so formed, that it will stand upright, with its mouth downwards: this velette, when filled with water, and covered with a slip of paper or thin pasteboard, prefixed close to it, to prevent the admission of common air, is inverted in another velette, b, with a little water in it, so that the slip of paper or pasteboard may be withdrawn, and the end of the pipe, c, introduced into it. This pipe is flexible and air-tight, and bent made of leather, fixed with a shoemaker's waxed thread. It is kept open at both ends by a piece of a quill, while one of them is introduced into the velette of water, and the other into the bladder d; the opposite end of which is tied round a perforated cork, kept open by a quill, and the cork is made to fit a phial, e, two-thirds of which should be filled with chalk just covered with water. Dr. Prieley has since found it most convenient to use a glasse tube; and to preserve the advantage which he had of agitating the velette, he makes use of two bladders, communicating by a perforated cork, to which they are both tied. He also observes, that the flexible pipe is not necessary; but instead of this a bent tube of glass must be ready to be inserted into the hole made in the cork, when the bladder containing the fixed air is separated from the phial in which it was generated. The extremity of this tube being put under the velette of water, and the bladder being compressed, the air will be conveyed into it, as in the other case. Instead of the bladder, a small phial may be introduced between the phial containing the chalk, &c. and the velette of water: for thus the chalk and water that may be thrown up the tube communicating with this phial will lodge at the bottom of the phial, while nothing but the air will get into the pipe communicating with the water. The apparatus being thus prepared, let the phial containing the chalk and water be detached from the bladder, and the pipe also from the velette of water; pour a little oil of vitriol upon the chalk and water; and having carefully prefixed all the common air out of the bladder, put the cork into the bottle presently after the effervescence has begun. Also prefix the bladder once more after a little of the newly-generated air has got into it, in order the more effectually to clear it of all the remains of the common air; and then introduce
PYRMONT WATER.

roduce the end of the pipe into the mouth of the vessel of
water, as in the drawing, and begin to agitate the chalk and
water briskly. This will presently produce a considerable
quantity of fixed air, which will defend the bladder. This
being previded, the air will force its way through the pipe,
and ascend into the vessel of water, the water at the same
time descending, and coming into the basin.

When about one-half of the water is forced out, let the
operator lay his hand upon the uppermost part of the vessel,
and shake it as briskly as he can, to throw the water out
of the basin; and in a few minutes the vessel will absorb
the air, and taking its place, will nearly fill the vessel as at
first. Then shake the phial containing the chalk and water
again, and force more air into the vessel, till upon the
whole, about an equal bulk of air has been thrown into it.
Also shake the water as before, till no more of the air can
be imbibed. As soon as this is perceived to be the case, the
water is ready for use; and if it be not used immediately,
should be put into a bottle as soon as possible, well corked,
and cemented. It will keep, however, very well, if the
bottle be only well corked, and kept with the mouth down-
wards.

It may be proper to observe on this process, that the
phial, n, should always be placed considerably lower than the
vessel m, so that the water to which the chalk is put should be
changed after every operation; that with a vessel of water
holding three pints, and a phial containing the chalk and
water of ten ounces, a little more than a tea-spoonful of oil
of vitriol will produce air enough to impregnate such a quan-
tity of water, that the whole process does not take up more
than a quarter of an hour, and the agitation not five minutes;
and that in this method the water is easily made to imbibe an
equal bulk of air; whereas Dr. Brownrigg found that Pyr-
mont water at the spring-head did not contain so much
as one-half. This apparatus has received considerable
improvements, which we shall briefly recite; but in justice
to the merit of the original inventor, his method deserves
to be recorded: and besides, it requires less time, and is
much less expensive than those that are now generally
used.

The apparatus contrived by Dr. Nook, and improved by
Mr. Parker, is represented in fig. 2. It is made of glass,
and stands on a wooden vessel, m, resembling a tea-board;
the middle vessel B has a neck, which is inserted into the
mouth of the vessel A, to which it is ground air-tight. This
lower neck of the vessel B has a glass stopple S, composed
of two parts, both having holes sufficient to let a good
quantity of air pass through them. Between these two parts
is left a small space, containing a plane-convex lens, which
acts as a valve, in letting the air pass from below upwards,
and hindering its return into the vessel A. The upper vessel
C terminates below in a tube t, which, being crooked,
hinders the immediate ascent to the bubbles of fixed air into
that vessel, before they reach the surface of the water in the
vessel B. The vessel C is also ground air-tight to the upper
neck of the middle vessel B, and has a stopple, s, fitted to
its upper mouth, which has a hole through its middle. The
upper vessel B holds just half as much as the middle one B;
and the end, n, of the crooked tube goes no lower than the
middle of the vessel B.

For the use of this apparatus, fill the middle vessel B
with spring or any other wholesome water, and join it to the
vessel C. Pour water into the vessel A (by the opening m,
or otherwise) so as to cover the riling part of its bottom:
about three-fourths of a pint will be sufficient. Fill an
ounce phial with oil of vitriol, and add it to the water, shaking
the vessel so as to mix them well together. A heat is gen-
rated, it will be hot to add the oil by a little at a time,
otherwise the vessel may be broke. Put this, through a
wide glass or paper funnel, about an ounce of powdered raw
chalk, or marble. White marble being first granulated, or
pounded like coarse sand, is better for the purpose than
pounded chalk, because it is harder; and, therefore, the
action of the diluted acid upon it is slower, and lasts a con-
iderable time. On this account the supply of fixed air from
it is more regular than with the chalk: and besides, when
no more air is produced, the water may be decanted from
the vessel A, and the white sediment washed off, and the
remains of granulated marble may be employed again, by adding
to it fresh water and a new quantity of oil of vitriol.
The funnel in this process is made use of in order to prevent
the powder from touching the inside of the vessel's mouth; for
if that happens, it will stick so strongly to the neck of the
vessel B, as not to admit of their being separated without
breaking. Place immediately the two vessels B and C (fast-
tened to each other) into the mouth of the vessel A, as in
the figure, and all the fixed air which is discharged from the
chalk or marble by the oil of vitriol, will pass up through
the valve in S into this vessel B. When this fixed air comes
to the top of the vessel B, it will dislodge from thence as
much water as is equal to its bulk; which water will be
forced up through the crooked tube into the upper vessel C.

Care must be taken not to shake the vessel A when the
powdered chalk is put in; otherwise a great and sudden
effervescence will ensue, which will perhaps expel part of
the contents. In such case it may be necessary to open a
little the stopple p, in order to give vent, otherwise the
vessel A may burst. It will be proper also to throw away
the contents, and wash the vessel C; for the matter will stick
between the necks of the vessels, and cement them together.
The operation must then be begun afresh. But if the chalk
be thrown in without shaking the machine, or if marble be
used, the effervescence will not be violent. If the chalk be
put into the vessel loosely wrapt up in paper, this accident
will be still better guarded against. When the effervescence
goes on well, the vessel C will soon be filled with water, and
the vessel B, half filled with air; which will easily be known
to the eye, by the air going up in large bubbles through
the crooked tube t.

When this is observed, take off the two vessels B and C
together as they are, and shake them so that the water and
air within them may be much agitated. A great part of the
fixed air will be absorbed into the water; as will appear
by the end of the crooked tube being considerably under
the surface of the water in the vessel C. The shaking them
for two or three minutes will be sufficient for this purpose.
These vessels must not be shook while joined to the under one
A, otherwise too great an effervescence will be occasioned
in the latter; together with the ill-consequences above-men-
tioned. After the water and air have been sufficiently agi-
tated, loosen the upper vessel C, so that the remaining wa-
ter may fall down into B, and the unabsorbed air pass out.
Put these vessels together, and replace them into the mouth
of A, in order that B may be again half filled with fixed air.
Shake the vessels B and C, and let out the unabsorbed air as
before. By repeating the operation three or four times, the
water will be sufficiently impregnated.

Whenever the effervescence nearly ceases in the vessel A,
it may be renewed by giving it a gentle shake, so that the
powdered chalk or marble at the bottom may be mixed with
the oil of vitriol and water above it; for then a greater
quantity of fixed air will be engendered.

When the effervescence can no longer be renewed by
shaking the vessel A, either more chalk must be put in, or
more
PYRMONT WATER.

more oil of vitriol; or more water, if neither of these produce the desired effects.

The ingenious Mr. Magellan has still farther improved the contrivance of Dr. Nook and Mr. Parker; he has two sets of the vessels B and C. While he is shaking the air and water contained in one of these sets, the other may be receiving fixed air from the vessel A. By this means twice the quantity of water may be impregnated in the same time. He has a wooden stand K (fig. 3.) to fix the vessels B, C, &c., when taken off from A, which is very convenient. He has a small tin trough for measuring the quantity of chalk or marble requisite for one operation, and a wide glass funnel for putting it through into the vessel A, to prevent its sticking to the sides, as mentioned before.

He has also contrived a flappole without a hole, to be used occasionally, instead of the perforated one p. It has a kind of bafon at the top, to hold an additional weight when necessary. (See fig. 4.) The flappole must be of a conical figure, and very loose; but exactly and smoothly ground as to be air-tight merely by its preasure, which may be increased by additional weights put into its bafon. Its ufe is to compress the fixed air on the water, and thereby increafe the impregnation; for by keeping the air on the water in this comprefled state, the latter may be made to sparkle like Champaign. And if the veffels are strong, there will be no danger of their bursting in the operation.

If the veffels be suffered to stand five or six hours, the water will be sufficiently impregnated even without agitation. But by employing the means above described, it may be done in as many minutes.

The water thus impregnated may be drawn out at the opening A. But if it is not wanted immediately, it will be better to let it remain in the machine, where it has no communication with the external air. Otherwise the fixed air flies off by degrees, and the water becomes rapid and flat; as also happens to other acridulous waters. But it may be kept a long time in bottles well stopped, especially if they are placed with their mouths downwards.

Mr. Blades of Ludgate-Hill has still farther improved this apparatus, by changing the flappole at k for a glass cock, which is more convenient. He has likewise altered the middle veffel B into a form more advantageous for the impregnation. See fig. 5.

For Dr. Hulme's method of impregnating water with fixed air, we refer to his "Safe and easy Remedy for the Stone," &c. 1778: observing, that he merely mixes the solution of fixed alkaline salt and water, containing as much vitriolic acid as it finds necessary, a priori, for neutralizing the alkaline, and expelling from it all its fixed air.

Dr. Withering, of Birmingham, has lately contrived a new apparatus for impregnating water with fixed air, which, he says, is preferable to that in common use, because it can be made at less expense, and is more easily prepared; because the whole operation of fixed air produced is converted to use, without any waste of the vitriolic acid; because it impregnates three times the quantity of water at one time, more completely and with less trouble; and the impregnated water will always retain its virtue, if the joints and cocks of the machine are made perfectly air-tight; for which purpose they should once a year be supplied with a small quantity of unfafted land. This apparatus is exhibited in fig. 6, and consists of a glass veffel A, about ten inches high in the cylindrical part, and fixed inches and a half in diameter; another glass veffel B, about twelve inches high in the conical part, one inch and a half in the neck, and five inches in diameter at the bottom; a copper pipe C passing through the flappole of the veffel B, and tied fast in the flexible tube D, made of strong leather, air-tight, and kept hollow by means of a spiral wire passing through its whole length; a conical brass pipe E, with a flappole fastened to the tube D; another conical pipe F, with a flappole G, into which the end of the tube E is accurately ground, so as to be air-tight, and cutting off all communication with the atmosphere when the pipe E is removed; two large hog's bladders H, H, each of which ought to hold two quarts; a flappole I, to prevent the water running into the bladders, when the veffel A is agitated; a bladder K, tied to the crooked tube with the flappole L, which occasionally opens or shuts the communication with the veffel B; a glass funnel M, accurately fitted with the glass flopper N; an aperture O, fitted with a glass flopper or a silver cork, from which the impregnated water is to be drawn for use; and, lastly, the tube P opening into the veffel A. When this apparatus is used, let the veffel A be filled with pure water, and any other ingredients that are required, in a proper proportion; into the veffel B put as much marble or whiting, in small lumps, as will cover its bottom to the height of about two inches, and pour in water to the height represented by the dotted line; let the mouth of the veffel A be well fitted with a cork, and through a hole in the cork pass the tube P, putting upon the cork melted sealing-wax of the softest kind, or modelling-wax, so as to make the whole air-tight. The modelling-wax may be procured at the engravers, or it may be prepared by adding to half a pound of melted bees-wax, two ounces of tallow, and one ounce of Venice turpentine; to this mafs add a sufficient quantity of red lead, or Spanish brown, to give it a colour, and let the mixture be flurred till it is cold; let the mouth of the veffel B be flopped with a piece of mahogany, turned into a conical figure in a lathe, and of a size somewhat larger than the mouth of the glasses will admit; put this piece of wood into melted bees-wax, and heat the wax till the wood begins to grow black: when cool, turn it again till it fliets the mouth of the veffel: the tubes C, L, and M, are fitted into holes bored through the wooden flappole, previous to its being immersed in the wax: put these tubes through the holes, and pref the flappole into the orifice of the veffel B, and cement the whole with sealing or modelling-wax: flut the flappoles I and L, having previously prefled the air out of the bladder K; open the flappoles G and E; then fluce the air out of the bladders H, H, and afterwards pref the conical pipe E into the pipe F: pour about a large spoonful of oil of vitriol through the funnel M, and flop it with its flopper N. The flaxible air let flowe by the efferefeence in the veffel B, riging through the tube C, paffes into the bladders H, H, and dilates them. In this case open the flappole I, and from the aperture O draw out about a quart of water; and the space before occupied by the water will be filled with flaxible air, whichfoon begins to be abforded by the remaining water, and is still supplied from the bladders H, H, and from the efferefeence mixture in the veffel B. When the bladders are considerably elfapsed, more vitriolic acid must be added through the funnel M, fo that they may be always kept pretty fully dilated. When an impregnation is speedily required, turn the flappoles at G and E, and open that at L; then separate the pipe E from the tube F, and agitate the veffel A; the flaxible air will paff into the bladder K, and may be prefled into the two other bladders, when the parts of the apparatus are united. During the agitation, the flappole at I should be clofed, and open only occasionally to flupply out of the bladders H, H, the flaxible air abforded by the water. If a strong impregnation be required, this process should be carried on in a room, the heat of which does not exceed forty-eight degrees of Fahrenheit's thermometer. Dr. Withering observes,
PYRMONT WATER.

observes, that the impregnated water receives no taint from the bladders; and that if the vessel A with its impregnated water be sepaparated from the vessel B, at the conical parting E F, it may be inclosed in a pyramidal mahogany cale, out of the lower part of which the cylinder cock at O projects; and thus serve for an ornamental as well as a luxurious and falubrious addition to the hide-board, particularly in the summer and autumnal feasons.

Mr. Henry has described a method of impregnating water in large quantities with fixed air, so as to give it the properties of mineral water, for the use of the sick on board of ships, and in hospitals. He has given the following account of his apparatus and process for this purpose. Cut off the two extremities of a calf's or pig's bladder (fig. 7) and having previously moutioned them, take one end and invert the top of the tubular fopper c, round the neck of which it is to be closely fastened with strong thread. Into the upper end introduce the part g of the long bent tube h, and tie them round in the same manner. The pipe b must be pulled through a hole formed by a hot iron burner, in a large cork adapted to the orifice i in the cale B, holding about ten or twelve gallons, to which it must be cemented: and the length of the pipe from this point must be such as to reach within a few inches of the bottom of the cale B, which is to be completely filled with fresh water, or such as has been recovered from lime. See Purifica-

tion of Water.

To a quantity of mild calcareous earth and water, placed in the air vessel C, add a small portion of strong vitriolic acid, and by the time molt of the common air may be sup-posed to be expelled by the fixed air arising from the mild calcareous earth, add a larger quantity of acid, and putting the tubulated fopper c in its place, the bladder f will become inflated. Pref it gently till its fides collapse; and then introducing the pipe b, with its cork, into the orifice i of the cale B, againpref the air forward, as it diftends the bladder into the water, where, bubbling up through the water, it will rise to the surface, and by its pressure, force the water to ascend into the funnel k, which is to be cemented into the head of the cale at l. In proportion as the water in the cale becomes impregnated with fixed air, that in the funnel will return into its place: but if, at any time, the latter should rise too high as to be in danger of overflowing, a quantity of air may be let out of the water cale, by means of the small plug m. And this is necessary to be done, occasionally, to discharge the residuum of the fixed air, which is not soluble in water.

If the operation be required to be performed more expeditiously, it may be quickened by agitating the water cale. To do this, the tubular fopper c must be withdrawn from the air-veeil, and supported, together with the bladder, by an assistant, while the cale B is shaken. During this time another tubular fopper must be put into the air-veeil, and it may be immersed into a quantity of lime-water to prevent waste. When the agitation has been continued for some minutes, in proportion to the falling of the water in the funnel, replace the fopper attached to the bladder f in the air-veeil when taken out of the lime-water, and proceed as before, repeating the agitation occasionally.

During the process, additional quantities of vitriolic acid may be introduced into the air-veeil through the opening at d, which is to be, at all other times, carefully secured with its fopper.

By this process, fixed air may be imparted to wine, beer, and almost any liquor whatever. And when beer is become flat or dead, it will be revived by this means; but the delicate agreeable flavour, and odorous taste communicated by the fixed air, and which is manifest in water, will hardly be perceived in wine, or other liquors, which have much taint of their own.

The artificial mineral waters thus made, are more pleasant to the taste than the natural Pyrmont or Seltzer waters; which, besides their fixed air, contain saline particles of a disagreeable taste, which are known to contribute little or nothing to their medical virtue, and may in some cafes, be hurtful. They are likewise conveniently storaged. According to Sir John Pringle, these waters may be made more nearly to resemble genuine Pyrmont water, by adding to each pint of them iron eight to ten drops of tinctura martis cum spiritu fals. Or this may be done, by adding to the water in the middle vessel B (fig. 2.) in the proportion of about thirty grains of Eplon salt, ten grains of common salt, a fersip of magnesia alba, and a draught of iron filings, or iron wire, clean and free from rust, to one gallon of spring water, and impregnating the whole with fixed air in the manner already described. Let them remain till the other ingredients, and as much of the iron as is necessary, are dissolved, which will be in two or three days; or the magnesia may be omitted, and then the operation will be finished in less than half that time. These waters may be rendered ferruginous or chalybeate very easily, by putting in the middle vessel two or more flender phials, filled with cuttings of fine iron-binding wire, or with small iron nails; because the impregnated water will dissolve the iron so fast, as to become well saturated with it in a few hours, according to the experiments of Mr. Lane. But the method of rendering these artificial waters chalybeate, used by Dr. Hulme, is to add one grain of salt of iron to each pint (sixteen ounces) of water already impregnated with fixed air.

The discovery of an easy method of impregnating water with fixed air is of great importance; as it is now well known that such water is a very powerful antifeptic, or that it both refists and corrects putrefaction. It is, therefore, given with great success in putrid fevers, in the febreezy, in dysenteries, in mortifications, and in other disorders arising from a putrid cause, or attended with putrefaction, a draught of it being taken now and then, or even by way of common drink. But the ingenious Mr. Bewly has invented a still better method of exhibiting fixed air as a medicine. He directs a spircle of alkaline falt to be dissolved in a sufficient quantity (a quarter of a pint, or less) of water, which is to be impregnated with as much fixed air as it can imbibe; this is to be drank for one dose. Mr. Bewly directs it to be prepared in larger quantities at a time, and calls it his nephitic julep. If immediately after it a spoonful of lemon juice, mixed with two or three spoonfuls of water, and sweetened with sugar, be drank, the fixed air will be extracted in the stomach; and thus a much greater quantity of it may be given than the same quantity of water alone can be made to imbibe. Fixed air acts as a corrombant; and, therefore, may be given with success in weakneks of the stomach, and in vomitings arising from that cause. It has also been given with success in fevers of the inflamed limb, and in nephritic complaints. When the lungs are purulent, fixed air, mixed with the air drawn into the lungs, has repeatedly been found to perform a cure. The bark alio may be given with advantage in water impregnated with fixed air, as they both coincide in the same intention. Fixed air may be applied by means of a syringe, funnel, or otherwise, to inflamed bleeds, putrid ulcers, mortified parts, ulcerated sore throats, and has been found in such and similar cafes to have very remarkable efficacy. It may also be given internally at the same time. In putrid dyenteries, and in putrid fevers, fixed air may be given by way of clyster.

Ferment-
By the magnet. It diffolves readily, and in considerable quantity in glasses of borax, and gives a colour indicating the presence of manganese and iron:—in phosphates of ammonia and soda it diffolves with great difficulty. Its constituents are silica, lime, iron, manganese, and muriatic acid. In the mine of Bialke it occurs mixed with iron ore, calcareous spar, and black crystallized malmolite. Pyromalolite was lately analyzed by Mr. Hilinger, who found its constituents to be as follows:

The escape of the acid by heat seems to indicate the presence of a portion of water amounting to about two-thirds of the loss stated as analyzed in the analysis. Annals of Philosophy, N°. 12.

**PYROGENUS**, formed of τις, fire, and ωστός, owing, is a term sometimes used for rectified spirit of wine; thus called because made by fire, or rather because rendered of a fiery nature.

**PYROET**, Pyroët, or rather Pyrolaët, in the Manager. See Piroëtte.

**Gen. Ch. Cal.** Perianth inferior, small, in five deep segments, permanent. Cor. Petals five, roundish, concave, spreading. Stam. Filaments ten, awl-shaped, shorter than the corolla; anthers drooping, large, with two horns at the base, each discharging the pollen by a terminal orifice. *Pyl.* Germin superior, roundish, angular; style cylindrical, permanent, various in length and direction, sometimes scarcely any; stigma thickish, variously shaped. Peri. Capsule roundish, depressed, five-sided, of five cells, bursting at the angles. Seeds numerous, chaffy.

Eff. Ch. Calyx in five deep segments. Petals five, Capu cele superior, five cells, bursting at the angles, and many seeds. Anthers with two pores.

Obf. In some species the filaments and style are erect; in others inclined to one side or the other; in some the former spread every way. The form of the stigma is different in different species. In two American ones the stigma is nearly, or quite, sessile; on which mark Mr. Purth’s genus Chimaphila is founded, its name being nearly synonymous with Winter-green, the English appellation of Pyrola. Section 1. Style elongated. Pyrolea of Purth. 1. P. rostratofolia. Round-leaved Winter-green. Linn. Sp. Pl. 567. Wildl. n. 1. Ait. n. 1. Purth n. 1. Engl. Bot. 213. (Pyrolea; Ger. Em. 408. Camer. Epit. 277. Kivim. Pentap. Irr. t. 136. f. 2. Pur. vulgat. Cluf. Hift. v. 2. 116. L. f. 467. L. sylvette).—Stamens ascending. Style twice as long, deflexed and recurved. Clutter many-flowered. Calyx as long as the filaments.—Native of thickets, for the most part
part in mountainous situations, in the more northern parts of Europe, also in North America, flowering in July. We have gathered it on the plains of mount Cenis, and in most parts of the sandy downs of Holland; opposite to which, on the Norfolk coast, this plant has likewise been found by the accurate Mr. L. Wieg, growing among bushes, on Bradwell common, not far from Yarmouth; where we likewise have seen it. There is more difficulty in ascertaining an indubitable figure of this species in the northern or mountainous parts of Britain, because of the plants having been so much confused with it, nor have we any specimen from those countries. The leaves are perennial, long, creeping, thread-shaped, feathery. Some very short and simple, leafy, solitary at the end of each shoot of the root. Leaves four or five; on bordered smooth fragfalks of various lengths (from one to two inches); roundish or elliptical, obtuse, an inch or inch and a half long, very obscurely crenate, smooth, shining, reticulated with numerous veins: paler beneath. Flower-flake terminal, solitary, about a span long, angular, slightly twisted, smooth, bearing a few scattered lanceolate membraneous bracteas, and terminating in a long, rather broad, calyx, of from four to eight, or ten large, handomely, white, drooping, but not quite pendulous, fragrant flowers, each having a similar bracteae to the roll, at the base of the partial flake, and fully equal to it in length. Segments of the calyx lanceolate, acute, full half the length of the petals, which, though usually rounded and blunt, have sometimes a pointed appearance. Stamens about the length of the calyx, all, turned upward, and crowded together; their anthers deflexed, yellow, with orange horns. *Germs* short, five-lobed. Stigma twice as long as the flamines, slender and quite pendulous in its lower part, gradually swelling towards the extremity, which is recurved. Stigma dilated, annular, with five small central points. Capsule the size of a pea, depressed, five-lobed, crowned with the permanent style and stigma.

2. *P. chlorantha*. Greenish-flowered Winter-green.—Swartz in Stockek. Trans. for 1812. 192 t. 5. (P. folio obtusa, flore viridiluco: Rivin. Pentap. Irr. t. 138 f. 11.)—Stamens slightly ascending. Style twice as long, club-shaped, deflexed and recurved. Chollar many-flowered. Calyx shorter than the flamines.—Native of Sweden, and probably, by the synonym of Rivinus, of Germany, flowering about the middle of July. Professor Swartz distinguishes it from the foregoing, by the smaller, often abrupt, leaves; flake almost dilute of bractae below; petals of a whitish, or yellowish, green hue; and flamines less curved upwards. We gather also, from his figure and description, that the bracteas which accompany each flower are much shorter than the partial flake, and that the calyx is shorter, and more close-preted, than in *P. retinudifolia*. In the posture and form of the flake we find no difference. The common flower-flake is remarkably spiral. Probably the P. folio retinudo of Rivinus, t. 137, may represent this species in England, as the posture of the permanent flake agrees better with it than with the following.

3. *P. media*. Intermediate Winter-green. Swartz in Steckek. Trans. for 1814 (not 1784), 257 t. 7 f. t. Engl. Bot. t. 1945. Winckle Guide, v. 2. 106. (P. retinudifolia; H. D. t. 116.)—Stamens regularly infixed. Style twice as long, deflexed perpendicularly. Cluster of many pendulous flowers. Calyx shorter than the flamines.—Native of bulky shady places in Sweden, and various parts of the north of England, flowering towards the end of June. We suspect also that this is the Oxalidaceae species, commonly mistaken for *minor*, and that it has often in Scotland, from whence we have specimens, been taken for *retinudifolia*. The leaves most agree with the last-named, but the flowers differ essentially in being smaller, more pendulous, and of a less pure yellow. The *flammen* are nearly twice the length of the calyx, all regularly and equally infixed, not at all turned upward. Style bent in a curve downward, its extremity furrowed, slightly thickened, vertical, not recurved. The flake is spiral, as in the last, with about two dilatant bracteas in its lower part, the bracteas which accompany each flower being nearly as long as the partial flake. Even Linneas may perhaps have confounded it with his true minor.

4. *P. minor*. Lesser Winter-green. Linn. Sp. Pl. 567. Wildl. n. 2. Act. n. 152. Eng. Bot. t. 1258. Fl. Dan. t. 55. Rivin. Pentap. Irr. t. 136 f. 1 1. (P. roes: Eng. Bot. t. 2543.)—Stamens regularly infixed. Style the same length, straight, stigma lobed, pointless. Cluster of many drooping flowers. Stalk straight.—Native of woods and thickets on the mountains of Europe; occurring in several parts of Scotland and the county of Durham, and flowering in July. This is smaller in general than any of the foregoing; the leaves more elliptical; flake straight, not spiral, with three principal angles and a smaller one, bearing a few broad bracteas near the base, but fearely any other, except the small awl-shaped ones at each partial flake. The flowers are very numerous, but small, drooping or even pendulous, white with more or less of a pink tinge. *Stamens* regularly incurved. Pores of the petals dilated, a little tubular. *Style* the size of a much shorter portion than parts of those we have hither mentioned; the flake large, five-lobed, deflexed, and divided into points, in the centre. We can no longer doubt that t. 158 and t. 2543 of English Botany represent one and the same species, which we pothe one from mount Cenis, Savoy, and Switzerland, as well as in the Linnaean herbarium. *P. media*, having been confounded by botanists in general with this, has caused all our perplexity expressed in Eng. Bot. 2543. The plant which Mr. Lightfoot introduced at Bulstede, we judge from memory to have been media; see Eng. Bot. 158.

5. *P. alpifolia*. Alpifoliate-leaved Winter-green. Michaux Boraeal-Am. v. 1. 251. Pursh n. 2.—"Leaves kidney-shaped. Stalk with a few feathering, convoluted, distal scales. Flowers turned every way. Style declining." *Michaux.*—Found by Michaux in Canada; by Pursh in beech woods on the mountains of Pennsylvania, flowering in July. The flowers are yellowish-green. If it were not for the "feathering scales," we should suspect this might be the same as our *chlorantha*, n. 2, whose leaves are often, it seems, short and abrupt; but we have seen no specimens answerable to either.

6. *P. dentata*. Toothed Winter-green. Leaves elliptic-ovate, obtuse, toothed. Stalk straight, obliquely angular, nearly naked. Stamens ascending. Style deflexed, strongly recurved. Stigma with a cylindrical point. Gathered by Mr. Menzies, on the west coast of North America. This species is readily distinguished from all others, hitherto discovered, by its leaves, which are obovate, or somewhat elliptical, one and half or two inches long, half or three quarters of an inch broad; their margin becket with very remarkable distinction, small, blunt teeth, usually near a quarter of an inch, and their surface not reticulated, but furnished with some series of connected branching veins, on each side the middle. Flower-flake triangular, about as long as the leaves. Flower-flake six inches long, nearly naked, round, very slightly angular, bearing a long peduncle of flowers, much resembling those of the wild species in size and structure, as well as in the position of their *flammen* but their *flake* is still more remarkably recurved, so as to form a semi-circle, and the point of the flake much more prominent, of a cylindrical shape, five-cleft at the summit. *P. ophylla*. Leafless Winter-green.—Stem and flake fealy,
fealy, without leaves. Anthers beaked. Style deflexed and recurved. Stigma with a cylindrical point.—Gathered on the west coast of North America, by Mr. Menzies, who affirms the plant is always quite deliáte of leaves, instead of which the angular stem bears numerous lanceolate, membranous, pointed scales, about half an inch in length, a few similar but more remote ones being scattered along the flat, which is angular. The flowers are nearly as large as the leaf, but our dried specimen will not allow us to determine the posture of the flowers. The anthers are long and narrow, with a small acute point at the contrary end to the pores. Style deflexed, its end somewhat recurved. Stigma with a long cylindrical point, like the leaf.

8. P. p. Variegated Winter-green.—Leaves ovate, somewhat serrated. Flowers drooping in all one way. Pores of the anthers contracted, tubular. Style curved. Stigma abrupt, with five small points. This was also found by Mr. Menzies on the west coast of North America. In some points it agrees with the two last, as well as with the 

Pyrola. Engl. Pores P. umbellata. Ger. in diameter, Cluf. to Virginia. paler P. umbellata. half 5. Fl. Willd. Footstalks American round (P. The Stigma WiUd. Mr. 3.) Cluf. 778. This appears to their Stamens It exclusively Florence! in this way, that they are crowded together into something like whorls, mounded, narrow-ovulate, bluish, strongly serrated; dark green and veiny above; paler beneath; about an inch and a half long. Flower-stalks terminal, solitary, three inches long, reddish, bearing about five, imperfectly umbellate, simple, partial stalks, each an inch long, spreading, rough with glandular pubescence, and sometimes furnished with a little lanceolate bracts. Flowers smaller than that of P. uniforma, but larger than any other of the foregoing, drooping. Petals orbicular, concave, cream-coloured; crinum at the base. Staminodes short, red, all irregularly infixed. Anthers shorter, purple, with white tubular pores, dilated and lobed at the orifice. Germin globosus, green. Style thick and very short, but certainly acute. Stigma orbicular, convex, with five flight notches. The American species are usually less umbellate, and more racemose, than the European.

Section 2. Stigma nearly fleshy. Chimaphila of Pursh.

11. P. umbellata. Umbellifer Winter-green. Linn. Sp. Pl. 567. Willd. n. 4. Ait. n. 4. Curt. Mag. t. 778. (P. tertia fruticans; Cluf. Hift. v. 2. 117. Ger. Em. 408. P. folio macronoto; Rivin. Pentap. Irr. t. 139. f. 2.)—Leaves ovate, acute, ferrated. Flowers somewhat umbellate. Stigma nearly fleshy. Stamen smooth. Native of woods in the northern parts of Europe, Asia and America, but not found wild in Britain. Mr. Menzies gathered it on the west coast of North America, and Mr. Pursh found it frequent in dry woods, from Canada to Virginia. Linneus, Gmelin, Pollich, Roth, &c. give it in their Floras. Dr. Sims, who received this species in flower in June, from Mr. Lodiges, justly affirms it to be the most beautiful of all the genus. The stem is woody, a span high, somewhat branched, angular, and roughish. Leaves crowded together into something like whorls, mounded, narrow-ovulate, bluish, strongly serrated; dark green and veiny above; paler beneath; about an inch and a half long. Flower-stalks terminal, solitary, three inches long, reddish, bearing about five, imperfectly umbellate, simple, partial stalks, each an inch long, spreading, rough with glandular pubescence, and sometimes furnished with a little lanceolate bracts. Flowers smaller than that of P. uniforma, but larger than any other of the foregoing, drooping. Petals orbicular, concave, cream-coloured; crinum at the base. Staminodes short, red, all irregularly infixed. Anthers shorter, purple, with white tubular pores, dilated and lobed at the orifice. Germin globosus, green. Style thick and very short, but certainly acute. Stigma orbicular, convex, with five flight notches. The American species are usually less umbellate, and more racemose, than the European.

ments from the north-west coast. It is now and then met with in our more curious gardens, requiring bog earth, with shade and moisture, and flowering in June and July. Its shrubby habit is like that of its kind, but of more humble growth. Leaves more pointed, with sharper tooth-like serratures; their upper surface marked, along the rib and veins, with a pale stripe. Partial flowers usually two, rarely three, dropping. Flowers the size of the leaf, but white. Stamens densely fringed in their lower part. Anthers with tubular jagged-mouthed pores. Style very short and thick. Sigmoid hemispherical, nearly entire, green. Mr. Pursh says this plant is in high esteem among the natives of North America for its medicinal qualities, and is called *Sipphetta*. He witnessed a successful cure of severe yaws by a decoction of this *Pyrola*.—We can by no means allude to the establishment of that able writer's genus *Chimaphila*, hinted at by Michaux; there being purely no diversity of habit to support it; nor any character, but a difference of length in the style; which the other species of *Pyrola* shew to afford admirable specific, but no generic, distinctions.

**PYROLAMPSIS**, in *Zoology*. See *Glows-worm*, and *Lampyris*.

**PYROLOGNEOUS ACID**, or *Empyreumatic acid of wood*, in *Chemistry*, a species of empyreumatic *Acerous Acid* (which see), procured by distilling in a glass or earthen retort a quantity of shavings of any kind of wood, such as box, guanacum wood, or beechn; in which case an extremely strong-smelling dark-coloured empyreumatic acid liquor is obtained, nearly one-third of the weight of the wood. This acid is stronger, and also much blacker and more empyreumatic, than either the *pyrenaceous* or *pyromuineous* acid, probably as requiring a stronger heat for its production. The acid of wood is obtained in a large quantity near London, from the preparation of charcoal for gunpowder, by distilling wood in cast-iron cylinders. It stains the hands deeply, and wood indelibly. This acid is procured in such a quantity as to be an object of manufacture. At the boil it is only an inferior acetic acid, and the difficulty of purifying it will prevent the profitable use of it in many of the arts to which vinegar is applied. However, as the process for procuring radical vinegar at the same time purifies this empyreumatic acid, it may probably be used for this purpose. It may be added, that much of the acid from the distilled charcoal for gunpowder, near London, is employed by calico-printers in forming the acetated iron, used as a mordant, as in this case the colour and smell of the acid are not at all detrimental. Some time ago Vauquelin announced, as a new discovery, that pyrologneous acid is identically the same as the acetic; but this was known to Glaner near 200 years ago. In the folio edition of his works, p. 188, may be seen directions for its distillation, with a copper-plate of the apparatus which he employed. He there calls it the vinegar of wood. Parker's *Chem. Catech.* p. 195, note.

**PYROMACHUS**, a name given by some to antimony, when reduced to a finely hardnefs; and by others to copper, when fused with sulphur, and thus rendered less ductile.

**PYROMANCY**, *Pyromantea*, a kind of divination, performed by means of fire.

The ancients imagined they could foretell futurity by inspecting fire and flame; to this end they considered its direction, or which way it turned. Sometimes they added other matter to the fire, e. g. a vessel full of urine, with its neck bound about with wool, watching narrowly on which side it would burst, and thence taking their augury. Sometimes they threw pitch on it, and if it took fire immediately, they esteemed it a good augury.

**PYROMETER**, formed of *pyr*, *fire*, and [*mes* Suces, *measures*, in *Physic*, the name of a machine contrived to measure the alteration of the dimensions of metals, and other solid bodies, arising from heat.

These instruments have been constructed of various forms; but as their object is to render the small expansions of solids apparent to the observer, they have consisted of a machine adapted to this purpose, and of an apparatus fit for heating the bodies under examination to a determined degree. The most usual, and, indeed, the most eligible mode of heating the bodies, is to place them in water, in which a thermometer is placed, and to heat the water by means of lamps. The small expansions of the heated solids have been rendered visible, either by multiplying-wheels, or by levers, or by fire wheels, which render a small motion communicated to one end of the mechanism productive of a great movement at the other end; and, secondly, by magnifying the small expansion through microscopes; which levers, upon the whole, to be the method that is both most certain and most manageable; for with wheels and pinions, and even with levers or firewheels, there is always some equivocal motion, arising from the loose connection of teeth and pinions, or from the firewheels and bending of other parts.

Mufchenbroek, who was the original inventor of this machine, has given a table of the expansion of the different metals, in the same degree of heat. Having prepared cylindrical rods of iron, steel, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the flame alone, when it began to freeze, and Fahrenheit's thermometer was at thirty-two degrees. The effects of which experiment are digested in the following table, where the degrees of expansion are marked in parts equal to the one-fourth part of an inch.

PYROMETER.

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments it appears, at first view, that iron is the least rarefied of any of these metals, whether it be heated by one or more flames; and therefore is most proper for making machines, or instruments, which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise, the measure of yards or feet should be made of iron, that their length may be as nearly as possible the same, summer and winter.

The expansion of lead and tin, by only one flame, is nearly the same; that is, almost double of the expansion of iron. It is likewise observable, that the flames, placed together, cause a greater rarefaction than when they have a tolerable interval between them; iron, in the former case, being expanded 117 degrees, and only 105 in the latter; the reason of which difference is obvious. By comparing the expansion of the same metal, produced by one, two, three, or more flames, it appears, that two flames do not cause double the expansion of one; nor three flames three times that expansion, but always less; and these expansions differ so much from the ratio of the number of flames, as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but some more, some less. Thus, tin began to run, when rared 219 degrees; whereas brass was expanded 377 degrees, and yet was far from melting.

As to the construction of M. Mushchenbroek's pyrometer, together with Defagulier's alterations and improvements, the curious may consult Defagul, Expem. Philol. vol. i. p. 421, &c. See also Mushchenbroek's translation of the experiments of the Academy del Cimento, printed at Leyden in 1731. And for a pyrometer of a new construction, by which the dilatations of metals in boiling fluids may be examined and compared with Fahrenheit's thermometer, see Mushchenbroek. Introd. ad Philosophiam Nat. 4to. 1752, vol. ii. p. 670.

But it has been observed, that M. Mushchenbroek's pyrometer was liable to some objections; and a contrivance was made, with a view of removing these, by Mr. Ellicott, who has given a description of his improved pyrometer in the Philosophical Transactions, N° 443. This may also be seen in Dr. Martyn's Abridgment, vol. viii. p. 464.

This instrument is formed with a flat piece of brass A A, (Plate XXIII. Miscellany, fig. 4.) which is screwed down to a thick piece of mahogany. Upon this plate are screwed three pieces of brass, two of which, B, B, serve to support the flat iron bar C, called the standard bar. The upper part of the third piece of brass is a circle D, about three inches in diameter, divided into three hundred and fifty equal parts, or degrees; within this circle is a moveable plate d, divided likewise into three hundred and fifty parts, and a small flem index. The bar of metal E, upon which the experiment is to be made, is laid on the standard bar. F is a lever two inches and a half long, fastened to an axis, which turns in two pieces of brass, screwed to one of the supports B. To the end of this lever is fastened a chain, or link-line, which, after being wound round a small cylinder, to which the index in the brass circle, D, is fastened, passes over a pulley, with a weight hung to the end of it. Upon the axis, to which the lever is fixed, is a piece of a quarter of inch diameter, to which a piece of watch-chain is fastened, the other end of which is hooked to a strong spring G, which bears against one end of the metal E.

H is a lever, exactly of the same form and dimensions with the other; but the chain fastened to the pulley on its axis is hooked to the standard bar. The line fastened to the end of this lever, after being wound round a cylinder, to which the moveable plate is fixed, passes over a small pulley, and has a weight hung to the end of it; or rather the same line, passing under a pulley to which the weight is hung, has its other end fastened to the lever F; so that one weight serves for both levers. From this description it is plain, that whenever the bar E is lengthened, it gives liberty to the weight to draw the lever F upwards by its action to the spring G; and the index will, at the same time, by means of the link line, be carried forward in the circle; and as the bar shortens, it will return back again; the same motion will be communicated to the standard bar. When the bar is lengthened the 20th part of an inch, the index will be carried once round the brass circle, which is divided into three hundred and fifty degrees; and, therefore, if the metal lengthens the 7260th part of an inch, the index will move one degree. In order to make an experiment with this instrument, lay a bar of any kind of metal, as iron, on the standard bar; then heat this bar to any degree of heat with a lamp, and mark the degree of its expansion, as indicated by the moveable plate; observe also the degree of expansion of the metal E, by the heat communicated to it from the standard bar, as marked on the brass circle by the index; let the instrument remain, till the whole be thoroughly cold; then removing the bar E, lay any others successively in its place, and proceed exactly as before; and thus the degrees of expansion of different metals, by the same degree of heat, may be estimated.

By the help of this instrument Mr. Ellicott found, upon a medium, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follows:

The great difference between the expansions of iron and brass, has been applied with good success to remedy the irregularities in pendulums arising from heat. Phil. Trans. vol. xxvi. p. 485. See Pendulum.

Mr. Graham used to measure the minute alterations, in length, of metal bars, by advancing the point of a micrometer-screw, till it feebly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four thousandth part of an inch. On this general principle Mr. Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw. A B C D (fig. 5) represents the main bar or bafil of this instrument; E F is the bar to be measured, lying in two notches, one fixed to the upright standard A B, the other to the principal lever H I; the end E of the bar E F bears against the point of G, a screw which is of use in examining the micrometer-screw; the other end of the bar F bears against a small pithically protuberant bit of hard metal, fixed at the fame height as G, in the principal lever H I; K is an arbor fixed in the bafil, which receives at each end the points of the screws, H, L, upon which the lever H I turns and serves as a fulcrum to it; O is a slender spring, to keep the lever in a bearing slate against the bar; and P is a clock, to prevent the lever from falling forward, when the bar is taken out; N is the feeder, somewhat in the shape of a T, intupled, and moveable up and down upon the points of the ferews; I, M,
PYROMETER.

I. M, which, as well as L, H, are so adjusted as to leave the motion free, but without shake; Q R is the handle of the feeder, moveable upon a loose joint at R, so that having hold of it at Q, the feeder is moved up and down, without being affected by the irregular preasure of the hand; the extremity, S, of the feeder is also furnished with a bit of protuberant hard metal, to render its contact with the point of the micrometer-screw more perfect; T is the micrometer-screw; V the divided index-plate; and W a knob for the handle; the micrometer-screw paffes through two solid fiwerced holes at D and Y; the piece YZ is made a little springy, and endeavours to pull the screw backwards from the hole at D, and consequently keeps the micrometer-screw constantly bearing against its threads the same way, and thereby renders the motion thereof perfectly steady and genet; X is the index, having divisions upon it, answering to the turns of the screw. This piece points out the divi-
sions of the plate, as the face of the plate points out the divisors upon the index. When the instrument is used, lay hold of the knob at Q with one hand, and, moving the feeder up and down, with the other move forward the screw T, till its point comes in contact with the feeder; then will the plate and index, V and X, shew the turns and parts. The shafts of this instrument, as well as the other parts of it, is brafs: one end of which is continued of the fame piece at right angles, to the height of three inches and a half; and the other end acts upon the middle of a lever of the sec-
ond kind, whole fulcrum is in the shafts; and, therefore, the motion of the extremity of the lever is double the differ-
ence between the expansion of the bar and the shafts. Hence, having the length of the lever from its fulcrum to the point of suspension of the feeder, the distance between the fulcrum and the point of contact with the bar, the inches and parts that correspond to a certain number of threads of the micrometer, and the number of divisions in the circum-
ference of the index-plate; the fraction of an inch expressed by one division of the plate may be deduced. Thofe mea-
sures are as follow: from the fulcrum of the lever to the feeder, 5.875 inches; from the fulcrum to the point of con-
tact, 2.895 inches; length of seventy threads of the screw, 2.555 inches; and the divisions in the circumference of the index-plate, 100. Hence the value of one division will be the \( \frac{1}{100} \) part of an inch: but if the screw be altered one-fourth of one of these divisions, when the contact be-
tween the screw and feeder is well adjusted, the difference of contact will be very perceivable to the slightest observer; and, consequently, \( \frac{1}{100} \) th part of an inch is perceivable in this instrument. When the instrument is made use of, it is immerged, together with the bar to be meafured, in a eif-
tern of water; which water, by means of lamps underneath, is made to receive any intended degree of heat not greater than that of boiling, and thereby communicates the fame degree of heat to the instrument, the bar, and to a mercurial thermometer immerged therein, for the purpose of ascertaining that degree. See fig. 6, in which A B is the eiftern, C the cover, which, when the instrument (fig. 5.) is raised upon blocks, goes on between the bar E F and the shafts B C; D a handle to take off the cover, when hot; E the mercurial thermometer; F the cock, to let out the water; and G H a hollow piece of tin, which supports feven spirit lamps, which are raised higher or lower by the screws I and K, in order to give the water in the eiftern a proper degree of heat. With this pyrometer Mr. Smeaton performed several experiments, which are arranged in a table; and their result agrees very well, he observes, with the proportions of expansions of feveral metals given by Mr. Ellipcott. The following table fhowis how much a foot

in length of each metal grows longer, by an increafe of heat correacting to 180° of Fahrenheit's thermometer, or to the difference between freezing and boiling water, expresfed in fuch parts of which the unit is equal to the 10,000th part of an inch.

1. White-glafs barometer-tube - 100.
2. Martian regular of antimony - 150.
4. Hard lead - 147.
5. Iron - 121.
7. Copper hammered - 204.
8. Copper eight parts, mixed with tin one - 218.
10. Brafs sixteen parts, with tin one - 229.
14. Fine pewter - 274.
16. Soft folder, wiz. lead two, tin one - 301.
17. Zinc eight parts, with tin one, a little hammered - 323.
18. Lead - 344.
19. Zinc or splinter - 353.
20. Zinc hammered half an inch per foot - 373.

For a farther account of this instrument, with its ufe, see Phil. Trans. vol. xviii. art. 79. p. 598, &c.

Mr. Ferguson has converfed and defcribed a pyrometer, which makes the expansion of metals by heat visible to the 45,000th part of an inch. The upper surface of this machine is reprefedented by fig. 7. Its frame, A B C D, is made of mahogany, on which is a circle divided into three hundred and fifty equal parts; and within that circle is an-
other, divided into eight equal parts. If the short bar E be pufted one inch forward (or toward the centre of the circle,) the index x will be turned 125 times round the circle of 360 parts or degrees. As 125 times 360 is 45,000, it is evident, that if the bar E be moved only the 45,000th part of an inch, the index will move one degree of the circle. But, as in this pyrometer the circle is nine inches in diameter, the motion of the index is visible to half a degree, which answers to the 90,000th part of an inch in the motion or pulling of the short bar E.

One end of a long bar of metal F is laid into a hollow place in a piece of iron G, which is fixed to the frame of the machine; and the other end of this bar is laid against the end of the short bar E, over the supporting cross-bar H; and, as the end, f, of the long bar is placed close against the end of the short bar, it is plain that if F expands, it will pull E forward; and turn the index x.

The machine stands upon four short pillars, high enough from a table, to let a spirit lamp be put on the table under the bar F; and, when that is done, the heat of the flame of the lamp expands the bar, and turns the index.

There are bars of different metals, as silver, brafs, and iron; all of the fame length as the bar F, for trying ex-
periments on the different expansion of different metals, by equal degrees of heat applied to them for equal lengths of time; which may be measured by a pendulum that twings seconds. Thus,

Put on the brafs bar F, and let the index to the 360th degree; then put the lighted lamp under the bar, and count the number of seconds in which the index goes round the plate, from 360 to 360 again; and then blow out the lamp, and take away the bar.

This done, put on an iron bar F where the brafs one was
was before, and then let the index to the 360th degree again. Light the lamp, and put it under the iron bar, and let it remain just as many seconds as it did under the bars one; and then blow it out, and you will see how many degrees the index has moved in the circle: and by that means you will know in what proportion the expansion of iron is to the expansion of 'bars'; which will be found to be as 210 is to 360, or as 7 to 12. By this method, the relative expansion of different metals may be found.

The bars ought to be exactly of equal size, and to have them so, they should be drawn, like wire, through a hole. When the lamp is blown out, you will see the index turn backward; which shows that the metal contracts as it cools.

The inside of this pyrometer is constructed as follows.

In fig. 8. A a is the short bar, which moves between rollers; and, on the side a, it has fifteen teeth in an inch, which take into the leaves of a pinion B (twelve in number), on whose axis is the wheel C of one hundred teeth, which take into the ten leaves of the pinion D, on whose axis is the wheel E of one hundred teeth, which take into the ten leaves of the pinion F, on the top of whose axis is the index above-mentioned.

Now, as the wheels C and E have one hundred teeth each, and the pinions D and F have ten leaves each, it is plain, that if the wheel C turns once round, the pinion F, and the index on its axis, will turn one hundred times round. But, as the first pinion B has only twelve leaves, and the bar A a that turns it has fifteen teeth in an inch, which is twelve and a fourth part more; one inch motion of the bar will cause the last pinion F to turn one hundred times round, and a fourth part of one hundred over and above, which is twenty-five. So that if A a be pushed one inch, F will be turned one hundred and twenty-five times round.

A silk thread b is tied to the axis of the pinion D, and wound several times round it; and the other end of the thread is tied to a piece of slender watch spring G, which is fixed in the fluid H. So that as the bar f expands, and pushes the bar A a forward, the thread winds round the angle, and draws out the spring; and as the bar contracts, the spring pulls back the thread, and turns the work contrary wise, which pushes back the short bar A a against the long bar f. This spring always keeps the teeth of the wheels in contact with the leaves of the pinions, and so prevents any shake in the teeth.

In fig. 7, the eight divisions of the inner circle are so many thousandth parts of an inch in the expansion or contraction of the bars; which is just one thousandth part of an inch for each division moved over by the index. Ferguson's Lectures on Mechanics, Suppl. p. 7, &c. 40.

Another pirimeter was invented by M. De Luc, in consequence of a hint suggested to him by Mr. Ramiden. The basis of this instrument is a rectangular piece of deal board two feet and a half long, fifteen inches broad, and one inch and a half thick, and to this all the other parts are fixed. This is mounted in the manner of a table, with four deal legs, each a foot long, and an inch and a half square, well fitted near its four angles, and kept together at the other ends by four firm crosspieces. This small table is suspended by a hook to a stand; the board being in a vertical situation in the direction of its grain, and bearing its legs forward in such a manner as that the cross-pieces which join them may form a frame, placed vertically facing the observer. This frame sustains a microscope, which is firmly fixed in another frame that moves in the former by means of grooves, but with a very considerable degree of tightness; the friction of which may be increased by the prelure of four screws. The inner sliding frame, which is likewise of deal, keeps the tube of the microscope in a horizontal position, and in great part without the frame, informing that the end which carries the lens is but little within the space between the frame and the board. This microscope is constructed in such a manner as that the object observed may be an inch distant from the lens; and it has a wire which is situated in the focus of the glasses, in which the objects appear reversed. At the top of the apparatus there is a piece of deal, an inch and a half thick, and two inches broad, laid in a horizontal direction from the board to the top of the frame. To this piece the rods of different fulblance, whose expansion by heat is to be measured, are suspended; one end of it slides into a socket, which is cut in the thickness of the board, and the other end, which rests upon the frame, meets there with a screw, which makes the piece move backwards and forwards, to bring the objects to the focus of the microscope. There is a cork very strongly driven through a hole bored vertically through this piece; and in another vertical hole, made through the cork, the rods are fixed at the top; so that they hang only, and their dilatation is not counteracted by any prelure. In order to heat the rods, a cylindrical bottle of thin glass, about twenty-one inches high, and four inches in diameter, is placed in the inside of the machine, upon a flint independent of the rest of the apparatus. In this bottle the rods are suspended at a little less than an inch distance from one of the sides, in order to have them near the microscope. Into this bottle is poured water of different degrees of heat, which must be flurred about by moving upwards and downwards, at one of the sides of the bottle, a little piece of wood fastened horizontally at the end of a flick: in this water is hung a thermometer, the ball of which reaches to the middle of the height of the rods. During these operations the water rises to the cork, which thus determines the length of the heated part; the bottle is covered to prevent the water from cooling too rapidly at the surface; and a thin cale of brass prevents the vapour from fixing upon the piece of deal to which the rods are fixed. This pyrometer is represented in fig. 9, in which a a is the fluid to which it is suspended; b the hook from which it hangs; c c e e the deal-board, which is the basis of the whole apparatus; d, d, d, d, four arms, to which is fixed the frame e e e e: the other frame which carries the microscope is g g: g, g, two cross-pieces, through which passes the tube of the microscope, and which support it near both ends; b b is the microscope; i its micrometer; k the cork, through which passes the glass rod l l, and by which it is kept suspended; m a rod of metal, or any other fulblance less dilatable than glass; n the point of union, obtained by means of two connected rings, in which both rods are fastened by screws: above these is another pair of rings, in which one of which the metal rod is free, and which rod it supports; s s the piece to which the glass rod is suspended; g a square piece fixed to the frame by four screws, behind which is a box, in which, as well as in a groove cut in the basis in p, the piece of silver, r a screw, which passes through the square piece g, whose chief is to move backwards or forwards the piece g, in order to bring the surface of the metal rod to the focus of the microscope: s, s, s, s, four screws, with round metal plates behind their heads, which serve to press the frame of the microscope against the frame e e e e; the longitudinal openings, through which the screws pass, permit the free motion of the first frame, when one strikes gently with a hammer to the bottom or the top of one of the sides. If the microscope is wanted higher or lower than the grooves permit, the screws may be re-
moved to other holes made on purpose in the side pieces of the frame are the cylindrical bottle, in which hung the rods in order to be heated at different degrees by water of various temperatures; y, y, are the supports of the bottle; x, the thermometer suspended in the water; y, a rod, to the lower end of which is fixed a small plate, to stir the water, by moving it up and down; z, a phython, one branch of which is within, and the other without, the bottle, the latter being furnished with a cock, which serves to draw off the quantity of water that is necessary for changing the temperature in the bottle. For a farther account of this instrument, together with the principle of its construction and use, both in the comparative measure of the expansions of bodies by heat, and the measure of their absolute expansion, and the experiments made with it, we must refer to an elaborate essay of M. De Luc on Pyrometry, &c., in the Phil. Trans. vol. lxxviii. part i. art. 20. p. 419—546.

All the contrivances above described must be considered as inferior to that constructed by Mr. Ramsden, of which general Roy has given an accurate and minute account in the Phil. Trans. vol. lxxx. p. 462. We shall here give such an account as our limits will allow of this instrument; the construction of which is so accurate, says major-general Roy, that it seems not easy to improve it; and refer for a fuller account illustrated by appropriate drawings. This pyrometer, named the microscope, because by means of two microscopes attached to it, the expansion is measured, consists of a strong deal frame, 5 feet long, nearly 28 inches broad, and about 42 inches in height. The metallic bar, whose expansion is to be measured, and which may be even five feet long, is placed in a copper trough little longer than five feet; and this is placed over 12 spirit lamps, the flames of which heat the water of that trough fully to the boiling point, and of course heat the bar which is plunged into it. Two other wooden troughs, also full of water, are placed parallel to, and at a little distance from, the copper one. Each of these contains a cast-iron prismatic bar. To the ends of one of these bars two microscopes are fastened in an horizontal situation, perpendicularly to the bars. One of these microscopes is furnished with a micrometer, or mechanism, to measure the magnified image of an object; the other microscope has a simple mark. The parts of the microscopes, as well as the proper marks for measurement, are so separated and disposed, partly upon the ends of the cast-iron rods, and partly upon the ends of the rod under examination, that if any of them be lengthened or shortened, that alteration is clearly perceived through the microscopes, and may be measured by means of the micrometer. It follows, that if the temperature of the cast-iron prismatic bars be kept unaltered, whilst that of the bar under examination is increased, then the increase of length, which is measured by the micrometer, must be attributed to that bar only, and by these means the expansions of several substances were ascertained. For further particulars relating to the construction and use of this instrument, we refer to the Transactins (ubi supra), and to the article Expansion in this Cyclopaedia. For an account of Wedgewood's pyrometer, see Thermometer. Also, for a description of Mr. Troughton's pyrometer, we are under the necessity of referring to the same article.

PYROMUCOUS ACID, or Empyromucous acid of sugar, or Syrupus acid, is different from the acid of sugar, or Oxalic Acid, (which see,) and denotes that punget acid vapour of sugar, or any facelarine matter strongly heated, which is familiar to every person who has ever entered a sugar-baking-house. It is prepared by chenills in the following manner: Put into a very large glas retort any quantity of pulverized sugar of any kind, so as to fill only 1/10 of it, as the matter very much swells in the process: adapt to it a large receiver, and closely luted, and heat it gradually on a sand-bath. A great quantity of gas arises when the sugar begins to be scorched, which is mostly carbonic acid mixed with an inflammable gas, probably the gaseous oxyd of carbon. In the receiver is condensed a weak aciduous liquor, coloured by an oily matter, and also apparently fouled by a portion of fuliginous matter volatilized during the distillation. The quantity of acid, obtainable in this process, varies according to the regulation of the fire, which should at least be pulsd so as to make the retort red hot, and to reduce the sugar to a perfect charcoal; but in general about 1/10 of the weight of sugar may be obtained of the distilled acid.

PYRONOMIA, a term used by the chemical writers to express the art of regulating fire, so as to make it subserve to all their purposes in a determinate degree.

PYROPE, in Mineralogy, a precious stone, formerly called the Bohemian garnet. (See Garnet.) The colour is a dark blood red; when held between the eye and the light, the red colour inclines to a yellow. The pyrope is never found crystallized, but occurs in small round or angular fragments imbedded in serpentine rock, or scattered in the sands on the sea-shore, and in alluvial ground. It fractures quartz. The specific gravity is stated by Klaproth 3:218. On account of its lustre, transparency, colour, and hardness, it is much prized by jewellers. The small grains, when powdered, are applied to cut softer stones. According to Klaproth, the constituent parts of pyrope are

- Silex 40.0
- Alumine 28.50
- Magnesia 10.00
- Lime 3.50
- Oxyd of iron 16.30
- Oxyd of manganese 0.25
- Lofs 1.25

PYROPHAGI. See FIRED EATERS.

PYROPHANES, in Mineralogy, a variety of the feldspar; so called because, being heated in a spoon, it becomes transparent, but retains its opaque state when cold, as Mr. Landriani has discovered. M. Saffure, junior, renders common hydrophanes transparent, and of a topaz colour, when heated by digesting them in melted wax. It is said that some pyrophanes are found in Armenia, which are transparent while exposed to the sun, and opaque at night. (See Gem.)

PYROPHORUS, formed of τυχε, fire, and ψευδός, I bear, in Chemistry, the name usually given to that substance called by some black phoropus; a chemical preparation possessing the fugular property of kindling spontaneously when exposed to the air.

This substance was accidentally discovered by M. Homburg, who prepared it of alum and human faces. (See Phosphorus Excelsus.) See also M. Le Fevre's preparation, described under Phosphorus of Sulfur.

It was apprehended for a considerable time after the discovery, that human faces were essential to the operation, till the young son of the great Lemeny found, that honey, sugar, flour, and, indeed, any animal or vegetable matter, might be substituted instead of the human faces; and since that time, M. de Sirvigny has shewn that most vitriolic salts may be substituted for the alun, having added to the aluminaes.
PYROPHORUS.

When half a dram of this pyrophorus is put on a piece of paper and exposed to air, it quickly kindles, becomes red like burning coal, emits a strongly sulphureous vapour, and burns the paper or other combustible body which supports it; and nothing is left but the white earthy bafe of the alum. When no sensible change takes place in the pyrophorus, either from a defect in the preparation, or from some air remaining in the phial that contains it, the combustion may be effected by breathing on the powder, and thus supplying it with the moifture which seems to be the primary agent in this phenomenon. The pyrophorus that is made by the method we have recited is fo highly inflammable as to take fire while it is falling from the mouth of the phial. If it be poured into a jar of pure oxygen gas, it forms a brilliant fiery shower; the oxygen is for the most part consumed, and there remain in the phial sulphurous acid and carbonic acid gases: the pyrophorus also being confumed with the exception of its aluminous bafe.

The spontaneous accension of the aluminous pyrophorus, on its being exposed to the air, has been a subject of confiderable discussion among chemifts and philofophers: several of whom have adopted the hypothefis propofed by M. de Suvigny, in the Ménusres de Mathematieque et de Phyfique, tom. ii. To explain this curious appearance, M. de Suvigny observes, that the vitriolic acid in the alum, during the calcination in the phial, leaves its earthy bafis, and unites with the phlogifon in the coal. By its union with this inflammable matter, a part of it is undoubtedly rendered volatile, and exhales partly under the form of volatile vitriolic acid, and partly in that of a blue sulphureous flame; while another part of it combines with the phlogifon forming a real sulphur, or an earthly hepaf sulphuris, in which the sulphur is protected from the fire by the earth with which it is combined, and the particles of which remain every where intermixed with thofe of the powder. Thus far (fays Mr. Befly, an excellent chemift and philofopher) M. de Suvigny is supported by the appearances, and by a juft chemical analysis of the powder: but he proceeds further, and fuppofes that, at the end of the process, a part of the vitriolic acid is left in a difengaged, or uncombined state, and highly concentrated. In this latter it is well known that this acid attracts moisture, and at the fame time generates a confiderable degree of heat. When the pyrophorus, therefore, is exposed to the air, he again fuppofes that this difengaged and concentrated acid suddenly attracts the watery particles floating in the atmosphere, and by the heat thus generated, sets fire to the sulphur and other inflammable matter contained in the powder. This hypothefis he has endeavoured to establish by the following obfervations; that the pyrophorus, as he apprehends, can be made only with substances fit for producing fulphur, or with sulphur itself:—that no pyrophorus will be produced, if the mixture be calcified by too long or too violent a fire; because then the whole vitriolic acid can be combined into perfect sulphur, and consequently is engaged, and not in a proper state to attract the moifure of the air; or else if it does not combine into sulphur, being half difengaged from its bafis, it is driven off by the violence or long continuance of the fire; and, consequently, after this complete calcination, no acid remains partly difengaged, as it ought to be, that it might unite with the water with fufficient activity:—that when the pyrophorus is very slowly moifened, as when it is kept in a bottle not well closed, it does not kindle, because fufficient heat is not produced by this flow and gradual attraction of water; it is also fpoil'd and rendered incapable of kindling, when exposed to the open air; because its acid becomes then faturated, or nearly faturated with moifure, and cannot, therefore, unite with that of the air with fufficient activity:—that a pyrophorus, thus fpoil'd by exposure to moifure, may be restored to its peculiar properties by making it again red-hot in a matraf; hence this calcination is partly...
PYROPHORUS.

difftengaged acid is again concentrated, and refumes all its
force of combining with water; and, laftly, that the in-
flammation of the pyrophorus is accelerated by placing it
upon a paper a little wetted, or by breathing upon it; becaufe
the acid then attracts the moifture more haftily, and confe-
quentially with more heat.

M. de Suvigny extends the fame reafoning to the feveral
other pyrophori which he discovered, similar to that of alun,
particularly to thofe which are made by subftituting vitri-
lolated tartar, Glauber's falt, and other vitriolic faltS with
metallic, earthy, or alkaline bodies, in the room of alun.
Mr. Bewly has examined this hypothefis with his ufual
accuracy and accuracy; and from numerous well-conducted
experiments he faid to concludc, that pyrophorus of all the
above-mentioned claffes may be prepared, differing from them
in no other particular, except that they contain no vitriolic
acid, and which nevertheless kindle readily, on being expoled
in the air, as thofe which have been impregnated with that
principle. In order to shew that the prefence of vitriolic
acid is not neceflary to confitute the pyrophorus made with
vitriolated tarfart, he added to a quantitty of this tartar
more than an equal weight of powdered charcoal, and cal-
cined the mixture a long time, in a red heat, in an open
crucible; frequently flirring the powder, in order to expel
from it as much of the vitriolic acid as poifible; the cal-
cination was aUoflS times repeated with fresh charcoal:
and yet on heating the falt, thus deprifed of a confeiderable
part of its acid, with charcoal, in a crucible or tobacca-
pipe, in the manner which we fhall here fendjoin, he obferved
no diminution in its quality of producing a pyrophorus.

Mr. Bewly, in feveral of his experiments, made use of
the bowl of a tobacco-pipe, in which he combined the ma-
terials, which he wifhed to examine in small quantities, and
in an expeditious manner: prefling them down flightly, fo
as to fill half or three-fourths of the bowl, and filling the
remainder of it with fine fand. This is kept in a red heat
twenty minutes, or half an hour; or it may continue there
two hours longer, if the operator pleafes, without any in-
jury to the pyrophorus. The pipe being taken out of the
fire, the matter is knocked out of it as soon as it becomes
cool, and generally, prettyfoon afterwards, takes fire fpont.
aneously. Thus he formed his pyrophorus with a mixture
confifling of two parts of alun, previously calcinfed in a
red heat; and of powdered charcoal and falt of tartar each
one part.

In another experiment, having added faccelfively various
and increasing quantities of fixed alkalS to the falt heated
as above, till the vitriolic acid contained in the mixture
might be confidered nearly as an evanescent quantity,
a pyrophorus was ftill produced on calcining it with
charcoal as before. He also mixed equal parts of falt of
tartar, and vegetable or animal coal, or sometimes three
parts of the former with two of the latter, and calcinfed them
in the ufual manner; and this compofition, on being expoed
to the air, generally kindled in halfl a minute or a minute;
though, as it contained no fulphur, it did not burn with so
much vivacity as the vitriolic pyrophorus. This, which Mr.
Bewly calls the alkaline pyrophorus, differs in no circum-
ftance from M. de Suvigny's neutral pyrophorus, except
in its not containing that principle to which he fcribes their
affencion. However, it might be fuppofed that the falt of tartar which he employed might accidentally contain
vitriolated tartar, or vitriolic acid; he repeated the expe-
riinent with tartar calcinfed by himfelf, as well as with nitre
fixed or alkalmJe by deflagration with charcoal, and with
iron filings; and in all these cafes with the fame refult.
By diverfifying in a like manner M. de Suvigny's experi-
ments on the metallic pyrophorus, Mr. Bewly found that none
of the three vitriols, heated with charcoal alone, in his ufual
method, could produce a pyrophorus. And thus he faved
that the addition of an alkaline falt to the composition, which
was a part of M. de Suvigny's proceed, was efential to its
feues.

Treatin in the ufual manner equal parts of calcined
green vitriol and charcoal, the powder which contained no
fulphur nor hepaf fulphuris, did not acquire any of the pro-
perities of a pyrophorus. The vitriolic acid feemed to have
been entirely diftilled; having no bafe to detain it, when
diffolved from the metallic earth. The charcoal and calx
of iron, left in this proceed, were calcined again, together
with fome falt of tartar; and a pyrophorus was produced,
which exhibited indications of its containing a fearcely per-
cettible portion of hepaf sulphuris. Thirty grains of crocus
moris affringens were calcinfed with fifteen grains of char-
coal, and the fame quantity of falt of tartar; and the mix-
ture burnt fpontaneously, though it contained no hepaf
fulphuris, or vitriolic acid. Having by these proceeds evinced
that metallic pyrophorus may be prepared without vitriolic
acid, Mr. Bewly proceeded to form an aluminous pyro-
phorus of the fame kind. For this purpofe, he procured
the earth of alun by a long and violent calcination; and
examining a part of it, he found, by the ufual tests,
that it neither contained any sulphur, hepaf sulphuris, nor
alum undecompounded. This he confidered as perfedfly
pure, though he afterwards found that it contained a small
quantity of vitriolated tartar: and yet it repeatedly fur-
fified a pyrophorus as active as when alun itself is employed.
From thefe and similar experiments he infers, that the feveral
kinds of pyrophori are not kindled by moifure attracted
by the vitriolic acid, as M. de Suvigny has maintained:
and his conclufion is farther confirmed by foine proceeds
of Dr. PrieJley, from which it appears, that they are kindled
in dry, nitrous, and depolfificated air.

M. Prouit, cited by Mr. Bewly, defcribes a variety of
new pyrophorus, which neither contain vitriolic acid, nor
feem likely to owe their affencion to the attraction of hu-
midity from the air. These principally confift of a coaly
matter fimpfly divided by metallic or other earts; fuch are
the feedment left in the filter in preparing Poulard's extrac-
t, various combinations of tartar, or its acid, or the acctuous
acid with metals, calcined earth, the coal, and charcoal.
Mr. Bewly, having evinced the inefficiency of M. de
Suvigny's theory, and difcovered that the pyrophori are not
kindled by moifure, attracted (merely) by the vitriolic acid,
directed his attention to the nitrous acid, which Dr. PrieJ-
ley has fhewn to be a conduflive part of atmospheric air,
as the probable agent in the production of this phenomenon.
The strong affinity which this acid has with phlogiston,
and the heat, and even flame, which it is known to produce with
certain inflammbale matters, manifefted that it was equal to
the effect; and having excluded the vitriolic acid from having
any effential concern in this operation, he fuppofes, either
that the pyrophorus is kindled by moifure attracted by fome
of the other ingredients which compofe it; or that it has the
power of decompounding atmospheric air, by suddenly
attracting its nitrous acid, and thereby generating a heat suf-
ficient to kindle the phlogifliff matter contained in it. This
idea appeared plausible, when he further confidered that Dr.
PrieJley produced the pureft repirable air with this fame acid
combined with other principles; and that this as well as
common air is diminished, and probably in part decom-
 pounded, in a variety of phlogifliff proceedes. This ingen-
ious writer concludes, upon the whole, from the proceeds
he hath made, that the pyrophorus feems to owe its fingu-
lar property to its being a combination of earth or alkali with phlogiston; the vitriolic acid, when present, only occasionally increasing or diminishing the effect, according to circumstances. In the processes of calcination, the earth or alkali principle is not merely mixed, but actually, though slowly, combined with the phlogistic principle of the coal; so that the pyrophorus, considering it in its most perfect state, is only a perfectly dry phlogisticated alkali or earth. On these data, the phenomena may be explained in the two following methods; with respect particularly to the influence of moisture and heat upon the pyrophorus. Supposing either the alkaline or earthy principles to have a greater affinity to water than to the phlogiston with which either of them is united, they may, instead of embosomed in a moist atmosphere, attract the humidity, and therefore set the phlogistic principle at liberty; which may, in its turn, attract and be ignited by, the fupposed aerial acid, its strong affinity to which is well known:—or, if this hypothesis be rejected, the inflammable matter may be kindled, merely in consequence of the heat produced by the combination of the alkali, &c. with moisture. This reasoning, however, supposes the existence of phlogiston, which modern chemists have generally exploded.

The chemical changes that take place during the formation and decomposition of pyrophorus, as they are stated by Aikin, appear to be the following: 1. By being heated below redness in the open air, the ingredients enter into fusion, and thus mix accurately with each other; then the water of crystallization is driven off from the alum, and of the fugar or flour, little else than the charcoal escapes volatilization. 2. The red heat to which it is exposed in the phial causes the sulphuric acid of the alum and charcoal of the fugar to react on each other, by which part of the charcoal is driven off in the form of carbonic acid, and part of the sulphuric acid escapes as sulphuric acid. The blue flame that characterizes the latter part of this process is probably caused by the volatilization and combination of a portion of sulphur, more than is requisite to saturate the potash of the alum. Thus the pyrophorus, when prepared, confists of alumine, charcoal, and sulphur of potash in intimate mixture.

3. When this powder is exposed to the air, a rapid decomposition of the air itself, and of the moisture which it contains, takes place, the oxygen of each being absorbed by the sulphur, while a sufficient quantity of heat is disengaged, to bring the charcoal and remainder of the charcoal to a state of actual inflammation. See on the subject of this article, Macquer's chemical dict. art. Pyrophorus; and Priestley's obi. on air, vol. iii. appendix, p. 386, &c. vol. iv. appendix. p. 479, &c. Aikin's dictionary.

PYROPHYLACIA, a term used by Kircher and some others, to express those magazines of fire which are placed in the cavities of mountains and other hollows of the earth, and serve to supply the several volcanoes in the different parts of the world. See volcano.

PYROPHYSALITE, in mineralogy, is so called from pyres, fire, and physis, a physis, because this mineral emits bubbles when exposed to the flame of the blowpipe. It is found at Minbo, near Falun, in Sweden, imbedded in a granitic rock. The colour of pyrophysalite is white, inclining to green, and occasionally small spots of blue flourspar are seen on its surface. It commonly occurs in oblong pieces, some of which approach to an irregular rhomboid. It differs from felspar, to which it has the most resemblance, in having but one determinate direction in which it can be split; its specific gravity is also greater, and it fuses more easily. The fragments scratch glass, but are less hard than quartz. The powder of the finest fragments emit a phosphorescent light when heated. Its specific gravity is 3.45, and the constituent parts, according to Heisinger and Bertelius, are

The substance lost during the process is suspected to be fluorite acid. Haute clays this mineral with the topaz. See Topaz. B.

PYROPECELOS, in the natural history of the ancients, the name by which they call the granite of Arabia, commonly known to this day under the name of the oriental granite.

The name is derived from the Greek, πυρός, fire, or fire-coloured, and πελακός, speckled; and the ancients having used the epithet fiery to yellow, as well as red, some have imagined the granite must be a yellow stone; but it is evident that red is the colour meant by it here.

PYROSCOPE, an instrument invented by professor Leslie for measuring the intensity of fire. This is merely the differential thermometer (which fee), with one of its balls covered with silver leaf, while the other is naked. The fire heats the naked ball, but not the silvered ball. Hence the liquid in the tube rises or falls, according to the intensity of the fire, and of course marks that intensity.

PYROSCOPIA, formed of πυρός, fire, and σκόπια, I consider, among the Greeks, a kind of divination, being the same with pyromancy and ignispiery.

PYROSIS, in medicine, called in Scotland the water-brook, is a disorder of the stomach, which is characterized by a sudden and violent attack of pain in that organ, followed by a copious discharge of a colourless, infipid, and generally cold fluid, resembling saliva, from the oesophagus, mouth, and throat.

The first description of this disease was given by Linneus, as a common affection of the Laplanders, under the appropriate appellation of Cardalga fluatoria; whence Sauvages gave it the denomination of pyrosis succinea. (Novel. Meth. clas viii. gen. 18.) Dr. Cullen adopted the generic term pyrosis, and deems it an idiotopathic disease. It seems to occur, however, in conjunction with other forms of indigestion, and might have been arranged as one of the symptoms of dyspepsia.

The fits of pyrosis usually come on in the morning and forenoon, when the stomach is empty. The first symptom is a pain at the pit of the stomach, with a sense of contriction, as if the stomach were drawn towards the back: the pain is increased by raising the body into an erect posture, and therefore the patient bends himself forward. This pain is frequently severe, with a sense of burning; and after continuing for some time, it brings on an evacuation of a thin watery fluid in considerable quantity. This fluid has sometimes an acid taste; but most commonly it is described as being absolutely infipid. It continues to be brought up for some time, and does not immediately give relief to the pain which preceded it; but at length it terminates the pain, and the fit ceases.

These paroxysms come on without any evident cause, nor is the origin of the diseased always to be imputed to any particular form of diet. It seldom, if ever, attacks people who use fresh animal food daily; but appears to be most common among those who live almost entirely upon tea, milk, potatoes, and farinaceous substances. It is much more common
common in women than in men; sometimes it attacks pregnant women, and often those who labour under leucorrhrea. It seldom occurs in any one before the age of puberty, or in those who are considerably advanced in life; when it has once taken place, it is very prone to recur occasionally for a long time afterwards. It is more common in Scotland than in this country, and chiefly affects the lower classes of the people.

While the same diet is continued, it is not always easy to cure the disease. The paroxysm is most effectually relieved by medicines, especially opium; hyoscynam, comium, &c. answer a similar purpose; and with its certainty; other stimulants and antiphlogisticas, as sulphur, water, ammonias, the tincture of guiaemum, &c. alleviate the fit. These remedies, however, do not materially contribute to prevent the recurrence of the paroxysms; and either, startling, and the whole of remedies against indigestion, have been often employed in vain. A combination of aromatic laxatives, with strong alkalies and narcotics, have appeared to the writer of this article to be the whole the most effectual remedies. See Cullen, First Lines, vol. iv. p. 1.

Pyrosis is also a word used to express an intense heat and redness in the face, such as that of persons who travel in extreme heat and weather, and the like.

Gen. Ch. Cal. Periarch inferior, short, in four deep, acute, broad segments, deciduous. Cor. of one petal, somewhat bell-shaped; tube three as long as the calyx, swelling gradually upwards; limb of the same length, in four acute, equal, spreading segments; throat downy. Stem. Filaments four, short, inserted into the tube of the corolla, alternate with the segments of the limb; anthers oblong, erect, pointed, shorter than the limb. Pfl. German. Turbine, inferior; style short, cylindrical; stigma capitata. Peric. Berry small, dry, pear-shaped, with eight furrows, and eight cells, destitute of any crown. Seeds solitary in each cell.

Eff. Ch. Calyx four-toothed. Corolla bell-shaped, four- lop, downy in the throat. Berry inferior, ob ovate, with eight furrows and eight seeds.

Obf. Jullien, by an error which seems typographical, attributes five segments to the corolla, which Willdenow corrected. There are, however, but four, as the analogy of the other parts, in this case, necessarily requires.

1. P. fulcrifusa. Willow-leaved Streak-berry, Willd. v. 1. (Pentandrae ceratoides; Lamarck Illust. v. 1. 289.; t. 68. f. 2.; not f. 4.) Gathered by Commeron, in the Isle of Bourbon; not, as Willdenow has it, the Mauritius. A shrub, with round, smooth, greyish, leafy branches. Leaves opposite, on short stalks, rather crowded, two or three inches long, elliptic lanceolate, serrate, entire, coriaceous, smooth, with one rib, and several lateral incurved veins, occasionally accompanied by an axillary gland-like tubercle, that forms a nodulose, pale beneath. Stipulae between the footstalk, and of the same length, awl-shaped, erect, dilated at the base, deciduous. Flowers in the axillary, solitary, somewhat immediate, bearing one or more simple, single-flowered, partial stalks, with a pair of oblong tapering bracts at the base of the latter. Flowers hardly a quarter of an inch long, erect, apparently white. Fruit, according to Lamarck, near an inch in length, pear-shaped, unii- lop, with eight long deep longitudinal furrows. When cut transversely, it shows the eight seeds, compressed, and radiating from the centre.

PYROTECHNY, derived from the Greek words πυρ, fire, and τεχνη, art, is a term applied to the art or science which teaches the management and application of fire in certain operations. Although this term has been used in a very extensive sense by some writers, and applied to the use and structure of firearms and artillery employed in the art of warfare, yet it is commonly confined, as it will be in this work, to those articles and instruments made use of for amusement, and for public occasions, as the celebration of victories, the demonstrations of public joy on account of peace, and in times of war, &c.

Of the origin of artificial fireworks there is nothing certain recorded. In Europe the invention of them is of recent date, and is given to the Italians. The use of fireworks in China was very general long before they were known in European countries: and from an account given of some recent exhibitions at Pekin, it should seem, that they have attained to a degree of perfection not surpassed even by the artists of England, France, or Italy. "The fireworks, in some particulars," says Mr. Bawow in his Travels in China, "excelled anything of the kind I had ever seen. In grandeur, magnificence, and variety, they were, I own, inferior to the Chinese fireworks we had seen at Batavia; but infinitely superior in point of novelty, neatness,
greatly admired; a shell five feet square was hoisted up by a pulley to the height of fifty or sixty feet from the ground; the bottom was so constructed as then suddenly to fall out, and make way for twenty or thirty fringes of lanterns enclosed in a box to descend from it, unfolding themselves from one another by degrees, so as at last to form a collection of full sixty, each having a light of a beautifully coloured flame burning brightly within it. This devotion and development of lanterns were several times repeated, and, at every time, exhibited a difference of colour and figure. On each side was a correspondence of smaller boxes, which opened in like manner as the others, and let down an immense network of fire, with divisions and compartments of various forms and dimensions, round and square, hexagons, octagons, &c., which shine like the brightest burnished copper, and flashed like prismatic lightning with every impulse of the wind. The diversity of colours with which the Chinese have the secret of clothing fire feoms one of the chief merits of their pyrotechny.

The apparatus used in making fire-works consists of solid wooden cylinders, called formors, for rolling the cases on; similar cylinders, either of wood or metal, for ramming down the composition; moulds for holding the cases while filling; a machine for contracting the cavity of the cases; another for grinding the materials; and a particular apparatus for boring some cases after they are filled.

Construction of the Cartridges for Rockets.—A rocket is a cartridge, or case made of thin paper, which, being filled in part with gunpowder, saltpetre, and charcoal, rifes of itself into the air when fire is applied to it. There are several kinds and sizes of rockets, but the three following are the principal: viz. 1. Small ones, the calibre of which is not larger than that of a bullet of a pound weight. 2. Rockets, the calibre of which is equal to the size of a ball of from one to three pounds weight. 3. Large rockets, equal to a ball of from three pounds to a hundred weight.

To give the cartridges the same length and thickness, they are put into a hollow cylinder of metal, or strong wood. This mould is to be confounded with another piece of wood, called the formor or roller, around which is rolled the thick paper employed to make the cartridge. The rule for the size of the mould and roller is this: if the calibre of the mould be divided into eight equal parts, the diameter of the roller must be equal to five of those parts; of course the vacuity between the roller and the interior surface of the mould is equal to 3/4s of the calibre of the mould, which will be exactly filled by the cartridge.

The size of the mould is measured by its calibre; but the length of the moulds for different rockets does not always bear the same proportion to the calibre, the length being diminished as the calibre is increased. In small rockets, the length of the mould ought to be six times the diameter of the calibre; but in the larger fixed rockets, it need not be more than between four and five times the calibre of the mould.

Large thin paper of a peculiar kind is employed in making cartridges, and hence it has obtained the name of cartridge-paper. This paper is wrapped round the roller, and then cemented by means of common pate. When the cartridge is formed, the roller is drawn almost out, by turning it round, until it is distant from the edge of the cartridge the length of its diameter. A piece of cord is then made to pass twice round the cartridge at the extremity of the roller; and into the vacuity left in the cartridge another roller is introduced, so as to leave a space between the two. By means of the cord, the cartridge must be pinched till there remains only an aperture capable of admitting an instrument called a piercer; then the cord is removed, and its place is supplied by a piece of packthread.

Besides the roller, a rod is employed to load the cartridge, which must be somewhat smaller than the roller, that it may be easily introduced into the cartridge. This rod is pierced lengthwise to a sufficient depth to receive the piercer, which must enter into the mould, and unite with it exactly at the lower part. The piercer, which decreases in size, is introduced into the cartridge through the part where it has been chocked, and serves to preserve a cavity within it.

After the cartridge is placed in the mould, the prepared composition is to be poured gradually in, and rammed down with great accuracy. When the cartridge is about half filled, separate, with a bodkin, half of the folds of the paper which remains, and having turned them back on the composition, press them down, and pierce three or four holes in the folded paper, by means of a piercer, which must be made to penetrate to the composition of the rocket. These holes serve to form a communication between the body of the rocket and the vacuity at the extremity of the cartridge, as it is called, or that part which has been left empty. In small rockets this vacuity is filled with granulated powder, and covered over, which serves to let them off; in those that are larger, the pot, containing flars, serpents, and running rockets, is adapted to it.

It now remains to affix the rocket to its rod, which is thus done. When it has been constructed, in the way just described, it is to be fastened to a rod of light smooth wood. Its length and weight must be proportioned to the size of the rocket; that is, it ought to be as long as to remain in equilibrium with it, when suspended on the finger, or other fucinculum, within an inch, or an inch and a half of the neck. Before it is fixed, place it with the neck downwards, and let it rest on two nails, in a direction perpendicular to the horizon; and to make it ascend to a greater height, adapt to its summit a pointed cap made of flat paper, which will serve to facilitate its pafsage through the air. To these rockets may be added several other things, as a petard, which is a box of tin plate filled with fine gunpowder, placed on the summit. The petard is placed on the composition, at the end where it has been filled, and the remaining paper of the cartridge is folded down over it, to keep it firm. The petard produces its effect when the rocket is in the air, and the composition is consumed. A representation of a rocket completely fitted up is given in Plate Pyrotechny, fig. 2.

Stars, serpents, &c. may be added to them, which is done by adjuncting to the head of the rocket an empty pot or cartridge, larger than the rocket, in order that it may contain the things intended to render the exhibition the more beautiful. The following tables are necessary to those who would manufacture rockets for themselves. The first shews the size of the calibre of the mould for rockets of a pound weight and below; and the second points out the size required for the calibres of moulds of from 1lb. to 5lbs. It must be observed, that a pound rocket is that which is just capable of admitting a leaden bullet of a pound weight, and so of the rest.

Here it is evident, that the mould of a rocket of twelve ounces in weight ought to be seventeen lines in diameter; one of five ounces will require a mould of thirteen lines in diameter. Hence we derive an easy method of finding the size when the weights are given: and if the diameter of the rocket be given, it will be equally easy to find the weight of the ball corresponding to that calibre. Thus, if the diameter is fifteen lines, it will, by the table, be seen that it corresponds to a ball of eight ounces.

</table>

By this second table, if the weight of the ball be given the size of the mould may be found: supposing it be 18 pounds, opposite to it is the number 262. Then we pay by the rule of proportion (as 19½, see Table I. is supposed to be divided into 100 parts), 100 : 19½ :: 262 to the fourth term sought, viz. 310.99; therefore the required calibre is 52 lines nearly, or four inches and four lines, or 4½ inches. But if the calibre be given in lines, the weight of the ball may be found: supposing the given calibre be 36 lines, then as 19½ : 100 :: 36 : 184. The nearest number in the table to this is 181, which shews that the weight of the ball will be rather more than 6 lbs., or, in other words, that a rocket, the diameter or calibre of which is 36 lines, is a rocket of a 6 lb. ball.

The composition of the powder for rockets must be different, according to the different sizes, it being completely ascertained that what is proper for small rockets would be too strong for the larger ones.

For rockets of one or two ounces, the composition should be one pound of gunpowder, and two ounces of finely ground soft charcoal.

For rockets of somewhat larger size, the composition may be ten ounces of gunpowder, three and a half of saltpetre, and three ounces of charcoal.

If the rockets be of five or six ounces weight, then to two pounds five ounces of gunpowder, add eight ounces of saltpetre, three ounces of sulphur, six ounces of charcoal, and two ounces of iron filings.

If the rockets be from ten to twelve ounces, you may add to seventeen ounces of gunpowder, four ounces of saltpetre, three and a half of sulphur, and one of charcoal.

For rockets of a pound weight: to one pound of gunpowder add one ounce of sulphur, and three ounces of charcoal.

For rockets of from four to seven pounds: to thirty-one pounds of saltpetre, add four pounds and a half of sulphur, and ten of charcoal: and for those that are still larger, we may add to eight pounds of saltpetre, one pound four ounces of sulphur, and two pounds twelve ounces of charcoal. In all cases the ingredients are to be pounded separately, and finely sifted before they are used. Gunpowder, thus reduced from the corns in which it is manufactured, is called meal-powder.

Mixes.—The mixes to let off rockets are thus made. Take linen, hemp, or cotton thread, and double it eight or ten times, if intended for large rockets, or only four or five times, if to be employed for flars. When the match is thus made, dip it in pure water, and being soaked, it is to be squeezed as dry as possible. Mix some gunpowder with a little water, so as to reduce it to a kind of paste, and immerse the match in it, turning and twisting it till it has imbibed a sufficient quantity of gunpowder; then sprinkle it over with dry powder, and when it is dry, it is fit for use.

In answer to the inquiry what causes rockets to ascend in the air, we may observe, that it is nearly the same as that which produces a recoil in fire-arms. Thus, when powder is inflamed in the chamber of a musket or cannon, it exerts its power against the breech of the piece, and against the bullet or wadding. But the resistance opposed by the bullet being much less than that opposed by the mass of the barrel or cannon, the bullet is forced out with great velocity. The cause of the ascent of a rocket is nearly the same. At the moment when the powder begins to inflame, its expansion produces a torrent of elastic fluid, which acts in every direction, that is, against the air which opposes its escape from the cartridge, and against the upper part of the rocket; but the resistance of the air is more considerable than the weight of the rocket; therefore the rocket ascends by the excess of the one of these forces over the other. This, however, would not be the case unless the rockets were pierced to a certain depth.

Brilliant Fire and Chinese Fire.—As iron-filings, when thrown into the fire, enflame and emit a strong light, this gave rise to the idea of rendering the fire of rockets much more brilliant, than when gunpowder, or the substances of which it is composed, are alone employed. But the Chinese have long been in possession of a method of rendering this fire much more brilliant and variegated in its colours. It consists in the use of a very simple ingredient, namely, cast iron reduced to a powder more or less fine: the Chinese give it a name that answers to iron-fire in our language. It is prepared from old iron pots pulverized, till the grains are not larger than radish seed. These, however, are pulled through sieves of different degrees of fineness; those that pass through the clothiest sieve, are called sand of the first order;
order; those which pass through the next sieve in size, and of the second order, and so on. This sand, when it inflames, emits an exceedingly vivid light, forming almost instantaneously luminous flowers and stars of various apparent magnitudes. It should be observed that rockets, into the composition of which iron-sayings and iron-sand enter, cannot be long preserved, owing to their readiness in attracting the moisture which the saltpetre gives out. The following tables exhibit the proportions of the different ingredients for rockets of this kind of from 12 to 33 lbs.

</table>

When these materials have been accurately weighed, the saltpetre and charcoal must be three times sifted through a hair sieve, in order to their being well mixed; the iron-sand is then to be moistened with brandy, to make the sulphur adhere, and then they are to be thoroughly incorporated.

The upper part of rockets is generally furnished with some composition, which takes fire when it has reached to its greatest height, emits a considerable blaze, or produces a loud report and whizzing noise. Of this kind are saucifions, maroons, stars, flowers of fire, &c. To make room for an article of this kind, the rocket is crowned with what is called a pot, which is larger than the rocket. (See fig. 3.) The following is the method of making this pot, and connecting it with the body of the rocket.

The mould for forming the pot, though of one piece, must consist of two cylindrical parts of different diameters. That on which the pot is rolled up must be three diameters of the rocket in length, and its diameter must be three fourths that of the rocket; the length of the other ought to be equal to two of these diameters, and its diameter to thirds that of the rocket. Having rolled the thick paper, intended for making the pot, twice round the cylinder, a portion of it must be pinned in that part of the cylinder which has the least diameter; this part must be pared in such a manner, as to leave only what is necessary for making the pot fall to the top of the rocket, and the figure must be covered with paper.

To charge such a pot, attached to a rocket. Having pierced three or four holes in the double paper which covers the vacuity of the rocket, pour over it a small quantity of the composition with which the rocket is filled, and by shaking it, make a part enter these holes; then arrange, in the pot, the composition with which it is to be charged, taking care not to introduce it a quantity heavier than the body of the rocket. The whole must be secured by means of a few small balls of paper, to keep everything in its place, and the pot must be covered with paper cemented to its edges; if a pointed summit be added to it, the rocket is fit for use.

Serpents.—These are small flying rockets, without rods, which, instead of rising in a perpendicular direction, mount obliquely, and descend in a zigzag form, without ascending to a great height. The composition of these is nearly the same as that of rockets, and the construction is as follows. The length, A C, (fig. 4.) of the cartridge is about four inches; it must be rolled on a stick somewhat larger than a goose-quill, and after being choaked at one of its ends, it is filled beyond the middle, as to B, with the composition; then it is to be pinched so as to leave a small aperture. The remainder, B C, must be filled with grained powder, which will occasion a report when it burns. Lastly, choak the cartridge entirely towards the extremity C; and at the other extremity, A, place a train of moift powder, to which, if fire be applied, it will be communicated to the composition in the part A B, and cause the whole to rise in the air. The serpent, as it falls, will make several turns in a zigzag direction, till the fire is communicated to the grained powder in the part B C; on which the serpent will burst with a loud report before it falls to the ground. The serpent cartridges are generally made of playing cards. These are rolled round a rod of iron or hard wood, and to confine the card a piece of strong paper is cemented over it. Larger serpents may be made by cementing two playing cards together, first moistened with water.

Maroons are small cubical boxes, filled with a composition proper for making them burst. To construct these, cut a piece of paffboard according to the method taught in geometry to form the cube (see fig. 5.); join these squares at the edges, leaving one only to be cemented, and fill the cavity of the cube with grained powder; then cement strong paper in various directions over the body, and wrap round it two rows of packthread, dipped in strong glue; then make a hole in one of the corners, and introduce into it a match. If the maroons are to be luminous, that is, which are to give out a brilliant light before they burst, they must be covered with a paste, the composition of which will be noticed below under Stars, and then rolled in meal powder to serve as a match or communication.

Saucifions differ from maroons only in form. The cartridge of the latter are round, and must be only four times their exterior diameter in length. They are choaked at one end in the same manner as a rocket, and a pellet of paper is driven into the aperture which has been left, in order to fill it up. They are then charged with corn powder, above which is placed a ball of paper, gently pressed down to prevent the powder from being bruised; the second end of the saucifion being now choaked, the edges are to be pared on both sides, and the whole is covered with several turas of packthread, dipped in strong glue, and then left to dry.

Stars are small globes which emit a molten brilliant light, so that, momentarily, they may be compared to the light of the stars in the heavens. These balls are not larger than a musket-ball, and when put into rockets they must be wrapped up in tow, prepared for the purpose. The composition of these stars is as follows: To a pound of fine mealed gunpowder, add four pounds of saltpetre, and two pounds of sulphur. When these ingredients are thoroughly mixed, take a piece as large as a small nutmeg, and having wrapped
wrapped it in a linen rag, or paper, form it into a ball; then tie it closely round with packthread, and pierce a hole through the middle of it, large enough to receive a piece of prepared tow, which is to serve as a match. This, when lighted, will exhibit a most beautiful appearance; because the fire as it flares from the two ends of the hole in the middle will extend to a great distance, and will make it seem very much larger than it actually is.

There are other compositions for flars; viz. with three ounces of faltpetre, mix one ounce of sulphur, and two drachms of mealed gunpowder; or with eight ounces of mealed powder, mix four ounces of sulphur, and the same quantity of faltpetre. When these materials have been well sifted, and sprinkled over with brandy, in which a small quantity of gum has been dissolved, the flar is made in the following manner. Take a rocket mould eight or nine lines in diameter, and introduce into it a nipple, the piercer of which is of an uniform fize throughout, and equal in length to the height of the mould. Put into this mould a cartridge, and by means of a pierced rod load it with one of the preceding compositions; when loaded, take it from the mould, without removing the nipple, the piercer of which paffes through the composition, and then cut the cartridge quite round into pieces of the thickness of three or four lines. The cartridge being thus cut, draw out the piercer gently, and the pieces which resemble the men employed for playing at drafts, pierced through the middle, will be flars, which must be filled on a match thread, that may be covered with tow. To give more brilliancy to flars of this kind, a cartridge thicker than that already described, and thinner than that of a flying rocket of the same fize, may be employed; but before it is cut in pieces, five orsix holes must be pierced in the circumference of each piece to be cut. When the cartridge is cut, and the pieces have been filled, cement over the composition small bits of a card, each having a hole in the middle, so that these holes may correspond to the place where the composition is pierced.

Étoiles à Pet are made in the same way nearly as faucifions already described, only that it will not be necessary to cover them with packthread: it will be sufficient if they are pierced at one end, in order that flars may be fastened to them, constructed according to the first method, the composition of which is dry; for if the composition be in the form of paste, there will be no need to tie it. In this case, a little more of the paper must be left hollow at the end of the faucifion which has been pierced for the purpose of introducing the composition, and to place in the vacuity, towards the neck of the faucifon, some grained powder, which will communicate fire to the faucifion when the composition is consumed.

Shower of Fires.—To form this sort of fire-work, mould small paper cartridges on an iron-rod two lines and a half in diameter, and make them two inches and a half in length. They must not be choked, it being sufficient to twill the end of the cartridge, and having put the rod into it to heat it, in order to make it assume its form. When the cartridges are filled, which is done by immerging them in the composition, fold down the other end, and then apply a match. This will fill the surrounding air with an undulating fire. The following compositions are given as proper for flars of this kind.

Chimney Fire.—Mealed gunpowder one pound, iron-filing two ounces, and charcoal two ounces.

Ancient Fire.—Mealed gunpowder one pound, charcoal two ounces.

Brilliant Fire.—Mealed gunpowder one pound, iron-filing four ounces. The firt of these compositions is thought to be the most beautiful.

Sparks differ from flars only in their fize and duration, for they are made smaller than flars, and are consumed sooner. They are thus prepared. Having put into an earthen vessel an ounce of mealed gunpowder, two ounces of pulverized faltpetre, one ounce of liquid faltpetre, and four ounces of camphor reduced to powder, pour over this mixture some gum-water, or brandy in which gum has been dissolved, till the composition becomes of the confluence of thick四种. Then take some lint which has been soaked in brandy, or in vinegar, or even in a solution of faltpetre, and being dried and unravelled, throw into the mixture such a quantity of it as is sufficient to absorb it entirely, taking care to flir it well. This composition may be formed into small balls about the fize of a pea, and being dried in the shade, and sprinkled with mealed powder, they will readily catch fire.

Sparks may be made by the following method: Take sawdust of fir, poplar, &c. and boil it in water in which faltpetre has been dissolved. When the water has boiled some time, it is to be poured off, that the sawdust may remain in the vessel. When nearly dry, it is to be spread out on a table, and sprinkled with sulphur sifted through a very fine sieve, to which may be added a little mealed powder.

Golden Rain.—Some flying rockets, which, as they fall, make small undulations in the air like frizzled hair, are called by the French writers fuées chévules, and by us bearded rockets; they finish with a kind of shower of fire, which is called golden rain, and they are constructed in the following manner. Fill the barrels of some goofe-quills with the composition of flying rockets, and place upon the mouth of each a little moist gunpowder, both to keep in the composition, and to serve as a match. If a flying rocket be then loaded with these quills, they will produce at the end a beautiful shower of fire, which is denominated golden rain.

Contrarieties, or Rockets that fly along a Rope.—A rocket may be made to run along an extended rope, by affixing to the rocket an empty cartridge, and introducing into it the rope which is to carry it along. Place the head of the rocket towards that side to which you intend it to move; if it is then set fire to, it will run along the rope without stopping till the matter it contains is entirely exhausted. If the rocket is to move in a retrograde direction, fill full one half of it with the composition, and cover it with a small round piece of wood, to serve as a partition between it, and that put into the other half; then make a hole below this partition, so as to correspond with a small canal filled with braided powder, and terminating at the other end of the rocket. By these means the fire, when it reaches the first half of the rocket, will be communicated through the hole into the small canal, which will convey it to the other end; and this end being then kindled, the rocket will move backwards, and return to the place from whence it set out.

Two rockets of equal size, bound together by strong packthread, and so arranged that the head of the one shall be opposite to the neck of the other, in order that when the fire has consumed the composition in the one, it may be communicated to that in the other, and oblige both of them to move in a retrograde direction, may likewise be adjusted to the rope by means of a piece of hollow reed. Rockets of this kind are generally employed for letting fire to various other pieces when large fire-works are exhibited; and to render
render them more striking, they are made in the form of different animals, such as serpents, dragons, &c.

To give a rocket a kind of rotary motion around the rope along which it advances, it will be sufficient to tie to it another rocket, placed in a transverse direction. But the aperture of the latter, instead of being at the bottom, ought to be in the side, near one of the ends. If both rockets be fired at the same time, the latter will make the other revolve around the rope, while it advances along it.

Rockets which burn in the Water.—In these there must be a considerable variation in the construction of the mortar, and also in the materials of which they are composed. The mould may be eight or nine inches in length, and an inch in diameter: the former, on which the cartridge is rolled up, may be nine lines in thickness. The composition should consist of three materials mixed together, viz. three ounces of mealed powder, one pound of falkpetre, and eight ounces of sulphur. If the rocket is to appear on the water with a beautiful sail, the composition must consist of eight ounces of gunpowder, one pound of falkpetre, eight ounces of ponded and finely sifted sulphur, and two ounces of charcoal. When the composition has been prepared according to these proportions, and the rocket has been filled in the manner above described, apply a suffusion to the end of it, and having covered the rocket with wax, pitch, &c. attach it to a small rod of white willow, about two feet in length, that the rocket may conveniently float. If it be required that these rockets should plunge down, and again rise up, a certain quantity of mealed gunpowder, without any mixture, must be introduced into them, at certain distances.

A rocket which is fired in the water, and, after burning there half the time of its duration, mounts into the air with great velocity, may be thus constructed. Take a flying rocket, furnished with a rod, and by means of a little glue attach it to a water-rocket, but only at the middle, A, (fig. 6,) in such a manner that the latter shall have its neck uppermost, and the other its neck downward. Adjust to their extremity, B, a small tube, to communicate the fire from the one to the other, and cover both with a coating of pitch, wax, &c. that they may not be damaged by the water. Then attach to the flying rocket, after it has been thus cemented to the aquatic one, a rod, as D, and from F suspend a piece of packthread, to support a musket bullet E, made fast to the rod by means of a needle or piece of iron wire. When these arrangements have been made, set fire to the part C after the rocket is in the water; and when the composition is consumed to B, the fire will be communicated through the small tube to the other rocket; the latter will then rise and leave the other, which will not be able to follow it, on account of the weight adhering to it.

Globes and Fire-Balls are made in different forms, viz. spherical, spheroidal, or cylinrical. The spherical are made in the following manner. Construct a hollow wooden globe of any size at pleasure, and very round both within and without, so that its thickness, A C or B D, (fig. 7,) may be about the ninth part of its diameter A B, and having an aperture, L M or O N, equal to the thickness A C or B D, that is, to the ninth part of the diameter A B. It is through this aperture that fire is communicated to the globe, when it has been filled with the proper composition, through the lower aperture I K. A petard of metal, loaded with good grained powder, is to be introduced also through the lower aperture, and to be placed horizontally. The aperture I K, which is nearly equal to the thickness, E F or G H, of the cylinder E F G H, is to be closed by means of a wooden tompon dipped in warm pitch; and melted over it such a quantity of lead that its weight may cause the globe to sink in water, till nothing remain above it but the part G H, which will be the case if the weight of the lead, with that of the globe and the composition, be equal to the weight of an equal volume of water. If the globe be then placed in the water, the lead, by its gravity, will keep the aperture, I K, directly downwards, and the cylinder, E F G H, in a perpendicular direction, to which fire must have been previously applied. The composition with which the globe must be filled, is as follows: to a pound of corned powder, add thirty-two pounds of falkpetre, eight pounds of sulphur, one eighth of scraped ivory, and eight pounds of sulphur previously boiled in a solution of falkpetre, and dried in the open air.

Globes which leap or roll on the Ground.—Having constructed a wooden globe A, (fig. 8,) with a cylinder C, similar to the one just described, and having loaded it with the same composition, introduce into it four or even more petards, loaded with good corned powder to their orifices, as is shown at A B, which must be well lapped with paper or tow. If a globe, prepared in this manner, be fired by means of a match at C, it will leap about as it burns, on a smooth horizontal plane, according as the petards are set on fire. The petards may be affixed to the exterior surface of the globe, as is seen in the figure, which they will cause to roll and leap as they catch fire.

Aerial Globes, called Bombs.—These globes are called aerials, because they are thrown into the air from a mortar. Though they are of wood, and have a suitable thickness, yet they are liable to burst unless the charge be nicely proportioned to their strength. The usual quantity is an ounce of powder for a globe of four pounds weight; two ounces for one of eight, &c. As the chamber of the mortar may be too large to contain the exact quantity of powder sufficient for the fire-ball, which ought to be placed immediately above the powder, in order that it may be expelled and set on fire at the same time, another mortar may be constructed of wood, or of paite-board with a wooden bottom, which may be put into the large iron mortar, to be loaded with a quantity of powder proportioned to the weight of the globe. This small mortar must be of light wood, or of paper pasted together, and rolled up in the form of a cylinder, but the bottom must be of wood. The chamber for the powder must be pierced obliquely, so that the aperture may correspond to the aperture of the mortar, when the fire upon the latter may be communicated to the powder which is at the bottom of the chamber, immediately below the globe.

The globe must be filled with several pieces of reed or cane, or common reed equal in length to the interior height of the globe, and charged with a flow composition, made of three ounces of mealed gunpowder, an ounce of sulphur moistened with a small quantity of petroleum oil, and two ounces of charcoal; and in order that these reeds or canes may catch fire the sooner, and with more facility, they must be charged at the lower end, which reft on the bottom of the globe, with pulverized gunpowder moistened with petroleum oil or brandy, and then dried. The bottom of the globe ought to be covered with gunpowder, partly mealed and partly corned, which, when set on fire, will communicate the fire to the lower part of the reed. Instead of reeds, the globe may be charged with running rockets, or paper petards, and a quantity of fiery flars or sparks mixed with mealed powder placed above these petards, which must be choked at unequal heights, that they may produce their effects at different times.

Jets of Fire are a sort of fixed rockets, the effect of which is to throw up into the air jets of fire similar to jets of water. N
They serve also to represent cascades, for if a series of such rockets be placed horizontally on the same line, it may be easily feen that the fire which they emit will resemble a sheet of water. When arranged in a circular form, like the radii of a circle, they form what is called a fixed fun. To form jets of this kind, the cartridge for brilliant fires muft, in thickness, be equal to a fourth part of the diameter, and for Chinefe fire only a fixth part. The cartridge is loaded on a nipple, having a point equal in length to the fame diameter, and in thickness to a fourth part of it; but as it generally happens that the mouth of the jet becomes larger than is necessary for the effect of the fire, the cartridge must be filled equal to a fourth part of the diameter with clay, which muft be rammed down. This will make the jet ascend much higher. When the charge is completed with the proper composition, the cartridge must be closed with a tompong of wood, above which it must be chocked. Jets intended for representing sheets of fire ought not to be chocked. They must be placed in a horizontal position, or inclined a little downwards. The following are the principal compositions for jets of fire.

1. For Jets of half an Inch or less in Diameter.—Chinefe fire: Saltpetre and bleared powder 1 b. each, fulphur 8 ounces; charcoal 2 ounces. White fire: Saltpetre 1 lb.; mealed powder 8 ounces; fulphur 3 ounces; charcoal 2 ounces; iron-fand of the firft order 8 ounces.

2. For Jets of an Inch or less in Diameter.—Brilliant fire: Mealed powder 1 lb., iron-filings 5 ounces. White fire: Saltpetre and mealed powder 1 lb. each; fulphur 8 ounces; charcoal 2 ounces. Chinefe fire: Saltpetre 16 ounces; fulphur 5 ounces; charcoal 5 ounces; iron-fand of the third order 12 ounces.

3. For Jets of 15 or 18 Lines in Diameter.—Chinefe fire: Saltpetre 16 ounces; fulphur 7 ounces; charcoal 5 ounces; of the several different kinds of iron-fand mixed 12 ounces.

Fires of different Colours.—For white fire the gunpowder must be mixed with iron or rather red-filings; for red fire, iron-fand of the firft order muft be employed in the fame way. Camphor mixed with the usual composition is laid to make the flame appear of a pale white colour. Rappings of ivory give a clear flame of a filver colour.

Pyrotechny.

Making, loading, and firing Pots des Bruns.—These are made of paffe-board, and muff be rolled pretty thick; usually made three or four inches in diameter, and four diameters long, and pinched with a neck at one end, like common cafes. A number of these are placed on a plank thus: having fixed on a plank two rows of wooden pegs, cut in the bottom of the plank a groove the whole length under each row of pegs; then, through the centre of each peg, bore a hole down to the groove at bottom, and on every peg fix and glue a pot, whose mouth must fit tight on the peg: through all the holes run a quick-match, one end of which must go into the pot, and the other into the groove, which must have a match laid in it from end to end, and covered with paper, fo that, when lighted at one end, it may discharge the whole almost instantaneously: in all the pots put about one ounce of meal and corn powder; then in some put flares, and others rains, flakes, serpents, crackers, &c.; when they are all loaded, paffe paper over their mouths. Two or three hundred of these pots being fired together, make a very pretty show, by affording fo great a variety of fires. Fig. 9 is a range of pots des bruns, with the leader A, by which they are fired.

Caduceus Rockets, in riving, form two spiral lines, or double worm, by reafon of their being placed obliquely, one opposite the other; and their counterpoife is in their centre, which caufes them to rife in a vertical direfion. Rockets for this purpofe muft have their ends choaked clofe, without either head or bosom, for a weight at top would be a great obftruction to their mounting; though they have been known sometimes to be bounced, but then they did not rife fo high as thoee that were not; nor do any caduceus rockets ascend fo high as fingle, because of their pertinent motion, and likewife the refiftance of air, which is much greater than two rockets of the fame size would meet with, if fired fingly.

By fig. 10, we fee the method of fixing these rockets: the thick for this purpofe muft have all their fides equal, which fides should be equal to the breadth of a flick proper for a lky-rocket of the fame weight as thoee we intend toufe, and to taper downwards as usual, long enough to balance them, one length of a rocket, from the crofs lick, which muft be placed from the large lick, fix diameters of one of the rockets, and its length seven diameters; fo that each rocket, when tied on, may form with the large lick an angle of thirty degrees. In tying on the rockets, place their heads on the opposite fides of the crofs lick, and their ends on the opposite fides of the long lick; then carry a leader from the mouth of one into that of the other. When these rockets are to be fired, fuppend them between two hooks or nails,
PYROTECHNY.

nails, then burn the leader through the middle, and both will take fire at the same time. Rockets of one pound are a good size for this use.

Illuminated Spiral Wheel.—First have a circular horizontal wheel, made two feet in diameter, with a hole quite through the nave; then take three thin pieces of deal, three feet long each, and three quarters of an inch broad each: one end of each of these pieces nail to the fell of the wheel, at an equal distance from one another, and the other end nail to a block with a hole in its bottom, which must be perpendicular with that in the block of the wheel, but not fo large. The wheel being thus made, take a hoop planed down very thin and flat; then nail one end of it to the fell of the wheel, and wind it round the fiek ficks in a spiral line, from the wheel to the block at top: on the top of this block fix a cafe of Chinefe fire; on the wheel you may place any number of cafes, which must incline downwards, and burn two at a time. If the wheel should confift of ten cafes, you may let the illuminations and Chinefe fire begin with the second cafes. The fpindle for this wheel must be a little longer than the cone, and made very smooth at top, on which the upper block is to turn, and the whole weight of the wheel to reft. See fig. 11.

Fruidon Wheels.—First take a nave, made nine inches long, and three in diameter; near the bottom of this nave fix eight spokes, with a hole in the end of each, large enough to receive a two or four-ounce cafe: each of these spokes may be fourteen inches long from the block. Near the top of this block fix eight more of the fame spokes, exactly over the others, but not fo long by two inches. As this wheel is to run horizontally, all the cafes in the spokes at top must play obliquely upwards, and all of them in the spokes at bottom obliquely downwards. This being done, take a small horizontal wheel, made with eight spokes, each five inches long from the block; on the top of this wheel place a cafe of brilliant fire: all the cafes on this wheel must play in an oblique direction downwards, and burn two at a time, and thole on the large wheel four at a time; that is, two of thole in the top fet of spokes, and two of them in the bottom fet of spokes. The four firft cafes on the large wheel, and the two firft on the small, must be fired at the fame time, and the brilliant fire at top, at the beginning of the laft cafes. The cafes of the wheels may be filled with a grey charge. When the wheels are completed, you must have a strong iron fpindle, made four feet fix inches long, and fixed perpendicular on the top of a ftand: on this put the large wheel, whose nave must have a hole quite through, from the bottom to the top. This hole must be large enough to turn easy round the bottom of the fpindle, at which place there must be a shouder, to keep the wheel from touching the ftand: at the top of the fpindle put the small wheel, and join it to a large one with a leader, in order to fire them both together.

Illuminated Glasses, with horizontal Wheels.—The hoops for these glasses may be made of wood, tin, or iron wire, about two feet in diameter. For a single globe take two hoops, and tie them together, one within the other, at right angles; then have a horizontal wheel made, whose diameter must be a little wider than the globe, and its nave fix inches long, on the top of which the globe is fixd, so as to fland three or four inches from the wheel: on this wheel you may put any number of cafes, filled with what charge you like; but let two of them burn at a time: they may be placed horizontally, or to incline downwards, just as you choose. Now, when the wheel is clothed, fix on the hoops as many illuminations as will ftand within two inches and a half of each other: thefe you fallen on the hoops with small iron binding

wire; and when they are all on, put on your pipes of communication, which must be so managed as to light them all with the second or third cafe on the wheel. The fpindle on which the globe is to run must go through the block of the wheel, up to the inside of the top of the globe, where must be fixed a bit of brass or iron, with a hole in it to receive the point of the fpindle, on which the whole weight of the wheel is to bear, as in fig. 12, which represents a globe on its fpindle. By this method may be made a crown, which is done by having the hoops bent in the form of a crown. Sometimes globes and crowns are ordered so as to stand fiff, and the wheel only to turn round; but when you would have the globe or crown to fland fiff, and the wheel to run by itfelf, the block of the wheel must not be fo long, nor the fpindle any longer, than to juft raise the globe a little above the wheel, and the wheel-cafes and illumination must begin together.

Dodecahedron, so called because it nearly reprefents a twelve-fided figure, and is made thus. Firft take a ball, turned out of some hard wood, fourteen inches in diameter: when done, divide its surface into fourteen equal parts, from where a hole an inch and a half in diameter perpendicular to the centre, so that they may all meet in the middle: then let there be fixed in the inside of each a female fpew; and to all the holes, but one, muft be made a round fpoke, five feet long, with four of the fpewes at one end, to fit the holes; then in the fpew of all the fpokes bore a hole, five inches up, which must be bored flanting, fo as to come out at one fide, a little above the fpew; from which cut a small groove along the fpoke, within fix inches of the other end, where you make another hole through to the other side of the fpoke: in this end fix a fpindle, on which put a small wheel, of three or four fides, each fide fix or seven inches long: thefe fides muft have grooves cut in them, large enough to receive a two or four-ounce cafe: when thefe wheels are clothed, put them on the fpindles, and at the end of each fpindle put a nut, to keep the wheel from falling off: the wheels being thus fixed, carry a pipe from the mouth of the firft cafe on each wheel, through the hole in the fide of the fpoke, and from thence along the groove, and through the other hole, fo as to hang out at the fpew end about an inch. The fpokes being all prepared in this manner, you muft have a poft, on which you intend to fire the work, with an iron fpew in the top of it, to fit one of the holes in the ball: on this fpew fix the ball; then in the top hole of the ball put a little meal powder, and some loofe quick-match; then fpew in all the fpokes, and in one fide of the ball bore a hole, in which put a leader, and fixure it at the end; and your work will be ready to be fired. By this leader the powder and match in the centre are fired, which will light the match at the ends of the fpokes all at once, whereby all the wheels will be lighted at once. There may be an addition to this piece, by fixing a small globe on each wheel, or one on the top wheel only. A grey charge will be proper for the wheel-cafes.

Trew-tree of brilliant Fires, is represented by fig. 13, as it appears when burning. Firft, let A be an upright piece of wood, four feet long, two inches broad, and one thick: at top of this piece, on the flat fide, fix a hoop, fourteen inches in diameter; and round its edge and front place illuminations, and in the centre a five-pointed star; then at E, which is one foot and a half from the edge of the hoop, place two cafes of brilliant fire, one on each fide: these cafes should be one foot long each: below these fix two more cafes of the fame fize, and at fuch a diftance, that their mouths may almoft meet them at top: then, close to the ends of these cafes, fix two more of the fame cafes; they muft fland pa-

N 2
rallied to them at E. The cates being thus fixed, clothe them with leaders, so that they, with the illuminations and flar at top, may all take fire together.

Illuminated Pear-tree.—First have a tree made of wood, such as is shewn by fig. 14. The middle piece, or item, on which the branches are fixed, must be eight feet six inches high: at the bottom of this piece draw a line, at right angles, two feet six inches long at each side; then from I, which is one foot six inches from the bottom, draw a line on each side to C and D: these lines will give the length of the two first branches. Then put on the two top branches parallel to them at bottom: let the length of each of these branches be one foot from the item: from the ends of these two branches draw a line to C and D: then fix on five more branches at an equal distance from each other, and their length will be determined by the lines A C and E D.

When the branches are fixed, place illuminating port-fires on the top of each, as many as you choose: behind the top of the item place a gerbe, or white fountain, which must be fired at the beginning of the illuminations on the tree.

Illuminated Seven-States.—Let fig. 15. be a smooth circular board, six feet diameter; out of the middle of it cut a circular piece twelve or fourteen inches diameter, and over the vacancy put while Perlain silk, on which paint a moon’s face; then let I, I, I, &c. be stars each four or five inches in diameter, cut out with five points, and covered with oiled silk: on the front of the large circular board draw a seven-pointed star, as large as the circle will allow; then on the lines which form this star bore holes, wherein fix pointed stars. When this piece is to be fired, it must be fixed upon the front of a poth, on a spindle, with a wheel of brilliant fire behind the face of the moon; so that while the wheel burns, the moon and stars will appear transparent, and when the wheel has burnt out, they will disappear, and the large star in front, which is formed of stars, will begin, being lighted by a pipe of communication from the last cafe of the vertical wheel, behind the moon: this pipe must be managed in the same manner as those in regulated pieces.

Pin Wheels.—First roll some paper pipes, about fourteen inches long each; these pipes must not be made thick of paper, two or three rounds of elephant paper being sufficient. When your pipes are thoroughly dried, you must have made a tin tube, twelve inches long, to fit easily into the pipes: at one end of this tube fix a small conical cup, which done is called a funnel; then bend one end of one of the pipes, and put the funnel in at the other, as far as it will reach, and fill the cup with composition; then draw out the funnel by a little at a time, flaking it up and down, and it will fill the pipe as it comes out. Having filled some pipes, and made some small blocks, about an inch in diameter, and half an inch thick; round one of these blocks wind and paste a pipe, and to the end of this pipe join another; which must be done by twisting the end of one pipe to a point, and putting it into the end of the other, with a little paste; in this manner join four or five pipes, winding them one upon the other, so as to form a spiral line. Having wound on your pipes, paste two slips of paper across them, to hold them together: besides these slips of paper the pipes must be balled together.

There is another method of making these wheels, called the French, which is, by winding on the pipe without paste, and shaking them together with sealing wax, at every half-turn; so that, when they are fired, the end will fall loose every time the fire pusses the wax; by which means the circle of fire will be considerably increased. The former for the first pipes are made from one-half to four-fifteenths of an inch diameter, and the composition for them as follows:

Order of Firing.

1. Two signal rockets.
2. Six fly rockets.
3. Two honorary.
4. Four caduceus.
5. Two vertical wheels illuminated.
6. Two spiral wheels illuminated.
7. Transparent stars.
8. A line rocket of five changes.
11. Air-balloons illuminated.
13. Regulating pieces of four mutations each.
15. Three large gerbes.
16. A flight of rockets.
17. Balloon wheels.
18. Cascades of brilliant fire.
19. Twelve sky-rockets.
20. Illuminated yew-trees.
22. Four tourbillons.
23. Fruiloni wheels.
24. Illuminated globes with horizontal wheels.
25. One pot des aigrettes.
26. Two plural wheels.
27. Marron battery.
28. Two chandlers illuminated.
29. Range of pots des brins.
30. Twelve sky-rockets.
31. Two yew-trees of fire.
32. Two double cones illuminated.
33. Regulating piece of seven mutations, viz.
1. Vertical wheel illuminated.
2. Golden glory.
3. Oktagon vertical wheel.
4. Porcupine's quills.
5. Cross fires.
7. Six vertical wheels.
35. Brilliant fun.
36. Large flight of rockets.

When water-works are to be exhibited, divide them into several sets, and fire one set after every fifth or sixth change of land and air-works. Observe this rule in firing a double set of works; always to begin with sky-rockets, then two moveable pieces, then two fixed pieces, and so on; ending with a large flight of rockets, or a maroon battery: if a single collection, fire a fixed piece after every wheel or two, and now and then some air and water-works. Jones's Fireworks, Nov. 1776.

PYROTECHNICAL SPONGE. See Sponge.

PYROTOCS, πυροτέχνης, formed from πῦρ, fire, in Medicine, caustics, or remedies, either actually or potentially hot; and which, accordingly, will burn the field, and raise an effect.

PYROUET. See Pirouette.

PYROXENE, in Mineralogy. See Augite and Lava. According to Haüy, the mineral called augite by Werner is the black or greenish-black variety of pyroxene found in volcanic countries and in basalt. The primitive form of the crystals of pyroxene is an oblique rhomboidal prism.

The greenish-transparent pyroxene, with the forms of the crystal distinctly marked, from the department of the Po, is the alabite of Bouvoin. Journal des Mines, No. 115.

The greyish-green, or whitish-grey variety, the primitive crystals of which are indistinct, from the same department, were called by Bouvoin malolite. Both these varieties have been called by some minerallogists diopside.

The greenish-green and opaque green pericthedral variety of pyroxene, is the fahlite of Werner, called also malcolithe by Haüy. The mineral called cocolite, discovered by Dandcada at the iron mines of Sudermannland and Nerika, in Sweden, and Arendahl in Norway, is also brought under the species pyroxene by Haüy. Tableau Comparatif.

By reducing many varieties of minerals under one species, Haüy may be considered as having rendered an additional service to mineralogy, already too much loaded with pedantic or unmeaning terms; but the term pyroxene itself may be justly objected to, as being founded not on any distinct character, but on the hypothetical assumption that these crystals are foreign to the igneous products in which they are imbedded, an assumption for which there does not appear sufficient proof. The constituent parts of pyroxene, its specific gravity and hardness, to nearly agree with those of basaltic hornblende, that these substances ought perhaps to be classed as varieties of the same species, without regarding the small difference of their crystalline forms. See Hornblende.

PYROXENE en Rockes, or Rock Pyroxene. In the Journal des Mines, Nov. 1812, a description is given of entire rocks composed of pyroxene, discovered by J. Charpentier in the Pyrenées. The substance is homogeneous, of a texture commonly granularly lamellar, which in some pieces becomes flat. Its most common colour is green of various shades, from an olive green to an emerald green, sometimes cloudy but often clear. From a greenish-grey it passes to a reddish-brown and ochre yellow. It is amorphous. The lullure is ippid. Its fracture is lamellar, and has a two-fold cleavage equally perfect, crossing at an angle of about 92°. In other directions the fracture is either imperfectly lamellar or conchoidal. It scratches glass, and gives some spark with steel. It melts with great difficulty by the blowpipe, but with horax it easily forms a green glass.

M. Vogel has analyzed this mineral, and discovered chrome in the green specimen. From the detailed description of this rock, it appears nearly allied to schiifcro, fiper, and ferpenite. It is frequently intimately combined with tale, in which it is not easy to distinguish it from ferpenite.

Rock pyroxene is found in beds in the primitive limestone, that forms a flat mountain superincumbent on granite, extending from the valley of Viedeflos, in the department of Arriege, to St. Beat, in the valley of Garonne. The mages of rock pyroxene are of extraordinary size, extending in length 5000 toises. Its thickness is difficult to determine, but is supposed to exceed 300 toises. Charpentier is disposed to class rock pyroxene as an intermediate rock between hornblende and ferpenite, and subordinated to primitive limestone. It neither contains foreign beds nor mineral veins, and is less liable to decomposition when pure, than almost any other rock. When intermixed with tale it decomposes rapidly.

PYRRHA, in Ancient Geography, a town of the Illyrians, between the promontory Sigriam and the town of Eretria, according to Ptolemy. The town took its name from a strait between Asia Minor and the island of Lebia, and gave it to a ferry in the same name.------Alfo, a town of Macedonia, in Magnesia. Pliny.—Alfo, a town of Asia Minor, in Lybia. Pliny.—Alfo, a town of Asia Minor, in Ionia, situated at the entrance of the northern part of the Latine gulf, E.N.E. of the town of Miketes, and S.S.E. of that of Myus. Strabo places it at 100 stadia from Heraclea.—Alfo, a promontory of Thessaly, upon the coast of the Phthiotides. Strabo, says, that before this promontory were two isles; one called Pyrrha, and the other Deucalion.—Alfo, a town of Greece, in the Phocié. Pliny.—Alfo, a town situated in the vicinity of the Pains-Meotis; submmered according to the relation of Pliny.—Alfo, a town of Asia Minor, in Caria.

PYRRHICHA, Πυρριχήα, in Antiquity, a kind of exercize on horseback; or a feigned combat, for the exercize of the cavalry.

It was thus called from its inventor Pyrrhicus, or Pyrrhus, in Cydonia, who first taught the Cretans to march in meaure and cadence to battle, and to observe the pace of the Pyrrhic foot. Others derive the name from Pyrrhus, son of Achilles, who instituted this exercize at the oblegions of his father. Aristotle says, that it was Achilles himself who invented it.

The Romans also called it ludus Trojanus, the Trojan game; and Aulus Gallius decorus. It is doubtles this exercize, that we see represented on medals, by two cavaliers in front, running with lances, and the word decorus in the exergum.

PYRRHICHIUS, Πυρριχίος, in the Greek and Latin Poetry, a foot consisting of two syllables, both short; as δευς. Among the ancients this foot is also called periothmus; by others hegemon.

PYRRHICUS, in Ancient Geography, a town of La- conia, upon the stream of Scyrax, S. of Hypsus. Here stood two temples, one of Diana Altarteia, and another of the Amazonian Apollo. The statues of these deities were of wood, and it is supposed they were placed here, by the Amazons themselves.

PYRRHO. See Pyrrhonians.
PYRHOCORAX, in Ornithology, a species of Corvus (which see), the Alpine crow of Latham, and the Choucas des Alpes of Buffon. Also, Pyrrhunculus, a parrot of the Monedula, Coracias of Aldrovand, &c., Cornishough, red-legged crow of Penang and Latham, and Corvus graculus, which see.

PYRHONIANS, Pyrrhonists, or Pyrrhonists, a sect of ancient philosophers, so called from their founder Pyrrho, a Greek philosopher, born at Elea, in Peloponnesus, who in early life studied painting, but aspiring to philosophical pursuits he became a disciple of Anaxarchus, and accompanied him as far as India. In this journey he followed Alexander the Great; and hence we may know in what time he flourished. In India he conversed with the Brahman and Gymnosophists, imbibing from their doctrine whatever might seem favourable to his natural disposition towards doubting; a disposition which was cherished by his master, who had formerly been a disciple of a sceptical philosopher, Metrodorus of Chios. As he was involved in fresh uncertainty by every advance he made in the study of philosophy, he left the school of the Dogmatists, who professed to be possessed of certain knowledge, and established a new school, in which he taught, that every object of human inquiry is involved in uncertainty, so that it is impossible ever to arrive at the knowledge of truth.

The distinguishing character of this philosopher was, that he professed to doubt of every thing, maintaining that men only judge of truth and falsehood from appearances, which deceive. On this principle he kept himself in continual suspension of mind, never determining on any thing; to avoid the inconveniences of error and false judgments.

He found in all things (says Boyle) reasons to affirm and to deny; and therefore he supposed after he had well examined the arguments pro and con, and reduced all his conclusions to a non liquet, let the matter be farther enquired into. Hence it is (says he) that he fought truth as long as he lived, but he so contrived the matter, as never to grant that he had found it. Though he is not the inventor of that method of philosophizing, yet it goes by his name. The art of disputing about everything, without doing any thing else but suspending one's judgment, is called Pyrrhonism, or Scepticism.

Some have said, that this philosopher acted upon his own principles, and carried his scepticism to an extreme so ridiculous, that his friends were obliged to accompany him wherever he went, that he might not be run over by carriages, or fall down precipices. These reports, however, are inconsistent with the respect that is paid to him by ancient writers, and with the general history of his life, and are charged, as calumnies, upon the Dogmatists, whom he opposed. A great part of his life was spent in solitude; and he always preferred a settled composure of countenance, undisturbed by fear, or joy, or grief. He endured bodily pain with great fortitude; and in the midst of dangers he manifested no signs of apprehension. As a debater, he was celebrated for the subtlety of his arguments, and the perspicuity of his language. So highly was Pyrrho esteemed by his countrymen, that they honoured him with the office of chief priest, and from respect to him, passed a decree by which all philosophers were indulged with an exemption from public taxes. Of the poets, and particularly of Homer, he was a great admirer; and frequently repeated passages from his poems. He flourished about the 11th olympiad, and died about the 90th year of his age, probably in the 123d olympiad, B.C. 288. After his death, the Athenians honoured his memory with a statue; and a monument, as Laertius informs us, was erected to him in his own country. His scepticism may in a great measure be ascribed to his early acquaintance with the system of Democritus. Having learned from this philosopher to deny the real existence of all qualities in bodies, except those that are essential to primary atoms, and to refer every thing else to the perceptions of the mind produced by external objects, that is, to appearance and opinion, he concluded, that all knowledge depended upon the fallacious report of the senses, and consequently, that there can be no such thing as certainty. In this notion he was encouraged by the general spirit of the Eleatic school, in which he was educated, which was unfavourable to science. But his scepticism was more confirmed by the subtleties of the Dialectic school, in which he was instructed by Bryton, the son of Stilpo. Regarding mental tranquillity as the great end of all philosophy, and observing that nothing contributed so much to disturb it, as the dilutions which agitated the schools of the Dogmatists, and also inferring from their endles disputes the uncertainty of the questions which they debated, he had recourse to the doctrine of universal uncertainty; and thus it happened in his case, as in that of many others, that controversy became the parent of scepticism.

Pyrrho had several disciples, but none who merit particular notice except Timon, the Philbrian, who lived to the age of 90 years, and flourished in the time of Ptolemy Philadelphus. The public succession of professors in the Pyrrhonic school terminated with Timon, and in Cicero's time this school was extinct. The disciples of Timon chose to screen their scepticism under the authority of the Academy; and after some interval, the school itself was revived by Ptolemaeus, a Cyrenian, and continued at Alexandria by Cenefiedemus, a contemporary with Cicero: the latter wrote a treatise "On the Principles of the Pyrrhonian Philosophy," the heads of which are preferred by Photius. From this time it was transmitted, through a series of professors little known, to Sextus Empiricus, who has given a summary of the sceptical doctrine; for an account of which, see Sceptics. As for Pyrrho and his followers, they rather endeavoured to demolish every other philosophical structure, than to erect one of their own. They affected nothing; but professed positions merely in the way of enunciation, without attempting to determine on which side, in any disputed question, the truth lay, or even presuming to affect, that one proposition was more probable than another.

Those now distinguished by the name of Pyrrhonians, or Sceptics, are persons who, from the great number of things that are dark and obscure, and from the avarice they bear to popular credulity, maintain, that there is nothing certain in the world.

The truth, Pyrrhonism has some foundation in nature: we do not judge of things from their real essences, but from their relations to ourselves. Most of our ideas we receive by means of our senses; but our senses are not given to judge of the essences, but of the relations of things to themselves; i.e. how they may affect us so as to do us good or harm.

Thus, c.e., our eyes do not give us the real magnitudes of objects, but their relative ones only.

The Academicks differed from the Pyrrhonians, in that they owned there were some things more like or more near akin to truth than others, which the Pyrrhonians peremptorily denied. On account of the similarity of the opinions of this sect and those of the Platonic school in the Middle and New Academy, it happened, that many of the real followers of Pyrrho chose to screen themselves from the reproach of universal scepticism, by calling themselves Academicks (which see); and hence the appellation of Pyrrhonists.
invaded each other's kingdoms; and in one instance, Pyrrhus gained so complete a victory over the principal general of his antagonist, and displayed so much courage, that he struck with admiration the Macedonians whom he had defeated, who dejected their own king, and chose Pyrrhus for their sovereign. This occurred in the year B.C. 287. He held this crown, however, a short time; for Lyrius, in the following year, entering the country with a powerful army, and remonstrating against the injustice of conferring the kingdom on a foreigner, in prejudice to him, a native and commander under Alexander the Great, the allegiance of the Macedonians seemed to Pyrrhus so little to be relied on, that he withdrew from the contest, and returned to Epirus. The Romans, engaged in a war with the Tarentines, looked for assistance to Pyrrhus. This prince eagerly listened to the proposal, and communicated his determination to his prime-minister Cynaeus, who, being more prudent than his master, endeavoured to dissuade him from it. The enterprise was, however, resolved on, and Cynaeus was sent with a body of troops to Tarentum, where he subverted the Roman influence, which was beginning to prevail, and obtained the command of the citadel for an Epirus officer. Pyrrhus followed, and having left his son Ptolemy regent of Epirus, landed in Italy, in the year 280 B.C., bringing with him an army of about 25,000 men, of whom 7000 were Macedonians, the veteran soldiers of Alexander the Great. He also brought a number of war-elephants, which was the first time that these animals were seen, in that character, in Italy. He was greatly endangered in his passage by a storm, which dispersed his fleet, and destroyed some of the ships that kept company with him. On his arrival at Tarentum, he began to correct the licentious manners of the inhabitants, and ensure them to military discipline. At length he marched out to meet the Roman consuls Valerianus, who was waiting for him on the bank of the Siris, in Lucania. The engagement was extremely obstinate, and Pyrrhus, who exerted himself in a manner worthy of his high reputation, was in great personal danger. Victory, however, decided in his favour, and he took possession of the enemy's camp. In interring the dead he made no distinction between his own men and the soldiers of his antagonist, but bestowed due encomium upon the bravery of his fallen foes. He followed up his victory, and had proceeded so far as to obtain a distant view of Rome. The advance of the other confuls obliged him to retire, and he financed his campaign by returning to Tarentum. Sensible that he had engaged in no easy task, he was delighted to receive an embassy from the Romans, which he imagined was to solicit peace, but it was only to negotiate an exchange of prisoners. In this embassy was included the virtuous Fabricius, whom he in vain attempted to gain to his interest by large offers. He then attempted to make a treaty, and sent his minister, Cynaeus, to Rome for that purpose, but was unsuccessful.

In the next campaign, two consuls with their armies marched against the king of Epirus; the battle was extremely bloody, and the victory so indecisive, that both parties claimed it: one of the consuls was killed, and Pyrrhus was severely wounded; and such was the lot of mess, that to one who congratulated him as having been the conqueror, he frankly replied, "Such another victory will ruin me." Both the consuls of the next year, one of whom was Fabricius, were employed to oppose Pyrrhus, who had received fresh reinforcements from Epirus. They advanced to the Tarentine territory, where, while they were seeking an opportunity to engage, an offer was made them by the physician of Pyrrhus, to take him off by poison. Detest-
ing the treachery, they informed the king of his danger, which so affected him, that he immediately liberated all his Roman prisoners without a ransom. He now sent Cynæa to Rome to renew the attempt at negotiation, but was again unsuccessful. During the state of perplexity in which a refusal had thrown him into, he was invited by the Syracusans and others to lend his aid against the Carthaginians, who had established themselves in Sicily. He accordingly seized the pretext for changing the field of action, and embarked the whole army for that island, leaving only a strong garrison in Tarentum. On his arrival he was received with general acclamations, and all the public force of Syracuse was put into his hands. He was soon so completely successful, that the Carthaginians sent deputies to Pyrrhus to treat for peace, but he refused to listen to any other condition, than that of their entirely evacuating the island. In confidence of success, he caused a fon to be proclaimed king of Sicily, and then made preparations to cross over into Africa, and carry the war into the Carthaginian territories. These projects were not agreeable to the Sicilians, who became alienated from him, and whom he treated not as friends, but as a conquered people. After this he quit Sicily, and embarked for Italy; in his voyage he was encountered at sea by a Carthaginian fleet, which sunk a number of his vessels and dispersed the rest, so that he reached a port in Italy with no more than twelve sail. Six years did he confine in Italy and Sicily, inflicting and suffering all the evils of war, and finally exhausted in force, and with diminished reputation. His religious spirit was not subdued; and for the purpose of employing and paying his soldiers, in conjunction with a body of Gauls, he made an irruption into Macedonia, where Antigonus Gonatas then reigned. His successes went beyond his expectations, for he not only obtained the pillage of many cities, but defeated Antigonus in battle, and wrested from him almost the whole kingdom. He now marched with a powerful army into the Peloponnesus, at the request of Cleonymus, and appearing before Sparta, required the inhabitants to receive his friend as their king. Upon their determination to resist this mandate, he attacked the city, but was repulsed with the loss of many men; he now retired to Argos, where, through the treachery of Aristeas, a bloody conflict ensued, during which, a woman, who saw Pyrrhus just going to kill her son, hurled a tile from the top of the house, which brought the king to the ground. In this state a Macedonian dragged him to a porch, and was going to cut off his head, when Pyrrhus opened his eyes, and gave him to see a look, that his trembling hand failed in its office, and it was not till after repeated strokes, that he could execute his purpose. Thus in the year 272 B.C. terminated the life and exploits of this great warrior, whose career with few enterprises ended alone could rival. His military skill was held in the highest estimation by the Romans, who were so well able to judge of it by experience. Hannibal considered Pyrrhus as second only to Alexander, as a great general. He is said to have been the first who understood the art of encampments, and of properly drawing up an army, and some treatises which he wrote on these subjects are mentioned by the ancients. He was brave to the borders of rashness, and sometimes led the commander of the soldiers. He had unbounded ambition, and a disposition perpetually to engage in new enterprises, for which, as we have seen, he readily abandoned such as proved more difficult than he had expected. He was fond of glory, but was puffed with generosity, which disposed him to acts of kindness, and to a grateful acknowledgment of obligations. All his foars were warlike, and he encouraged the dispo-

**PYRUS**, an ancient Latin name, which botanists have adopted, but of which the most correct orthography perhaps would be Pirus. This will appear as we trace its etymology, but more trouble than good would now arise from such a correction. The generality of critics have given rather a forced derivation of this word, from its Greek synonym, πυρος, the a being suppoed cut off, and an r introduced; but De Theis has proposed a much more probable one, from the Celtic pear, whence the Anglo-Saxons have taken pear, the English pear, and the French poire. According to the same writer, api, the Celtic name of a fruit of the kind of this is, the origin of the Greek ἄβης, the German apfel, and our apple. Api is even the particular name of one sort of apple, in the French language.—Linn. Gen. 251. Schreb. 339. Willd. Sp. Pl. v. 2. 1012. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 531. Prodr. Fl. Grec. Sibth. v. 1. Ait. Hort. Kew. v. 3. 207. Pursh 339. Jull. 335. Tourn. t. 404. Lamarck Illutr. t. 435. Gern. t. 87. (Mauls; Jull. 334. Tourn. t. 406. Codoni; Jull. 335. Tourn. t. 405. Sorbus; Linn. Gen. 250. Schreb. 338. Jull. 335. Lamarck Illutr. t. 434. Crataegus; Linn. Gen. 250. Schreb. 338. Jull. 335. Lamarck Illutr. t. 434. Cliffs and Order. Icacinia Pent. Linn. Nat. Ord. Fl. 1704. Raphanus, Jull. 335. G. n. Ch. Col. Perianth superior, of one kind, concave, with five spreading segments, permanent. Cor. Petals five, roundish, concave, inserted by their claws into the calyx. Stam. Filaments twenty, awl-shaped, shorter than the corolla, inserted into the calyx; anthers simple, roundish. Pfl. German inferior, roundish; Rykes from two to five, thread-shaped, the length of the stamens; figmas bluntish. **Pyr.**
PYRUS.

Peric. Apple roundish, umbilicated, fleshy, with from two to five membranous, more or less rigid, cells. Seeds two, rarely more, in each cell, oblong, obtuse, pointed at the base, convex on one side, flat on the other.

Eff. Ch. Calyx five-cleft. Petals five. Apple inferior, of from two to five cells. Seeds two in each cell.

Our remarks under the article MeSFILUS apply equally to the present genus, as to the propriety of referring to it the whole Linnean genus of Sorbus, and some species of Crataegus and MeSFILUS; disregarding the difference in the number of their styles, which is evidently uncertain and variable, and distinguishing MeSFILUS by its berry, Pyrus by its apple. Even this distinction proves, in some instances, obfcuré enough. We shall, for convenience, follow Willdenow in the order of the species, introducing our additional ones according to their affinities.

1. P. arbusfolia. Arbutus-leaved Dwarf Apple. Linn. Suppl. 256. Wild. n. 1. Ait. n. 1. Purf. n. 1. Wan- genh. Amer. 89. t. 28. f. 64. (MeSFILUS arbusfolia; Linn. Sp. Pl. 685. Crataegus virginiana, folis arbuti; Mill. t. 190.).—Leaves obovate, pointed, ferrated; downy beneath; their mid-rib glandular above. Flowers corymbose. Calyx downy.—Common in low copses and swamps, from Canada to Carolina, flowering in May and June. Purf. Frequent in gardens. A bushy farub, without thorns, three or four feet high. Leaves two inches long, nearly ferrated, more or less downy. Flowers white, terminal. Fruit red, the size of a currant, mealy, and not edible.

4. P. ovulis. Oval Berry Apple. Wildl. n. 3. Purf. n. 4. (MeSFILUS Alm~lanchier? Walt. Carol. 148. Cra-t~gus p~cat~a; Lamm. Dict. t. 1. 84.).—Leaves roundish-elliptical, acute, ferrated, smooth. Flowers raceme. Petals obovate. Gemen and segments of the calyx downy.—Native of swamps, from New Jersey to Carolina, flowering in April and May. A small farub; the fruit black, edible. Purf. Lamarck, who first distinguished this species, says it is twice or thrice as tall as the following, at least in the French gardens, with rounder leaves and smaller flowers, while the fruit is larger, being as big as a floe. The narrow-coloured deciduous brodat~s moreover, which occur in both species, are in the present longer than each partial flower-flalks, which is not the case with P. Alm~lanchier.

256. Wildl. n. 4. Ait. n. 3. (MeSFILUS Alm~lanchier; Linn. Sp. Pl. 685. Jacqu. Austr. t. 300. Mill. t. 178. f. 1. Vaccinia alba; Ger. Em. 1416.).—Leaves roundish-elliptical, acute, ferrated; downy beneath. Flowers racemo~e. Petals lanceolate. Germen somewhat downy. Segments of the calyx smooth.—Native of rocky mountainous situations in Germany, Switzerland, France, and the Isle of Crete; common in shruberies, ever since Gerarde's time, blooming in May. From three to six feet high, or more when cultivated, making an elegant appearance with its copious dropping clusters of snow~flowers, whose flarks are very woolly. Fruit blue-fine-black, fweet, the size of a currant.

6. P. c~rica. Cretan Berry Apple. Wildl. n. 5. Prodr. Fl. Grceci. n. 1157. (Chameeeerus Idaea; Alpin. Exot. 4.).—Leaves roundish, emarginate, with a small point, ferrate; woolly beneath. Flowers race-mote. Petals lanceolate. Germen and segments of the calyx woolly.—Found on the mountains of Crete. This differs from the last, of which it is justly suspected of being a mere variety, in having rounder leaves, whose pubescence underneath is more permanent; as well as in having more woolly leaves of the flowers.

8. P. com~ons. Common Pear-tree. Linn. Sp. Pl. 686. Wildl. n. 6. Ait. n. 4. Sm. Fl. Brit. n. 1. Engl. Bot. t. 1784.—Leaves ovate, ferrated, finally smooth. Flowers carpets corymbose. Fruit elongated at the base.—Native of various parts of Europe, but even more general as a cultivated plant, the varieties of whose whole fruit are many of them highly valuable for the table. The truly wild, or iron, pear is not eatable. It blooms in April or May. The tree is tall and handsome; the wood light, fine-grained, and tolerably hard, making neat furniture. The branches, at first erect, subsequently become curved downwards, and pendulous. The serratures of the leaves commonly disappear by culture, as do the strong thorns: found on the wild tree. When young, the leaves are downy beneath, and fringed with white. Flowers white, with pale red anters; their inflorrence corymbose, not umbellate as in the apple. Fruit ovate, more or less elongated at the base.

9. P. pol~era. Woolly-leaved Pear-tree. Linn. Mant. 2. 244. Wildl. n. 7. Ait. n. 5. (P. pollinwetana; Baur. Hift. v. 1. 59. Munch. Hauv. v. 3. part 2. 333.).—Leaves ovate, strongly ferrated; woolly beneath. Flowers carpets corymbose, subdivided.—Native of Germany, according to baron Munchhausen. John Bauhin first met with it in the garden of baron Polivill, in Alfalia. It was sent to Kew, in 1786, by the late Mr. Graeffer. This differs from the common Pear-tree in having the leaves downy on both sides, but especially beneath; the flowers cream-coloured, much smaller and more numerous, even forty in each corymbose, their partial flarks being branched and forked. The fruit is small, sometimes but an inch long, and falls easily when ripe.

flowering early in May. The leaves are whitish and silky beneath; nearly smooth above. Flowers large, white, strongly scented, in a simple downy corimb. Fruit about two inches in diameter, globose, rather depressed, purplish-green. When gathered in October, as twigs as an unripe medlar; but after lying a few weeks, it first acquires a sweet scent, which is but temporary, and at length towards December, these pears become soft, like medlars, and very good eating.

11. P. malus. Common Apple, or Crab-tree. Linn. Sp. Pl. 686. Wild. n. 9. Ait. n. 6. Sm. Fl. Brit. n. 2. Engl. Bot. t. 179. Fld. Dan. t. 1101. Mill. Ill. t. 44. (Malus sylvestris; Ger. Em. 1461.)—Leaves elliptic-oblong, pointed, serrated, smooth. Styles simple, stigmas. Styles smooth.—Native of woods and hedges throughout Europe, and still more valuable, for its innumerous and useful varieties, as a cultivated plant, than even the Pear, n. 8. The Crab itself, or Wild Apple, though always too autore to be eaten raw, is subject to some varieties that are worthy of notice for kitchen use. This species produces its elegant bluish-coloured blossoms in May. The branches are more horizontal than those of P. communis, as also more twisted and diverger. The younger leaves are downy beneath. Fruit roundish, convex, or umbilicate, at the base.

12. P. sylvestris. Dioscorides Pear-tree. Wild. n. 23. Phytogr. falc. L. 8. Morcach. Weidett. 87. t. 8. Wild. (Malingon floreos, fructicos tamen; Bauh. Pin. 432.)—Leaves oval, pointed, serrated. Flowers axillary, dioecious. Petals linear, the length of the calyx.—The native country of this singular plant is unknown. Professor Wildenow, from whom we have dried specimens, suspects it to be possibly a variety of the preceding species. The flowers are small, forming in appearance short downy umbels, at the ends of the branches, but each separate stalk is accompanied by a leaf. Petals yellowish-green, not exceeding the calyx. Styles five, smooth. We have seen the female plant only.

13. P. spectabilis. Chinese Apple-tree. Ait. n. 7. Wild. n. 11. Curr. Mag. t. 267. Schneer. Ic. t. 15.—Leaves oval-oblong, serrated, smooth. Umbels simple, fiddle, nearly smooth, without bracteas. Styles woolly at the base.—Native of China, from whence Dr. Fothergill is said to have imported it in 1780. The tree grows tolerably hardy in our gardens, flowering early in May. The leaves are furnished with copious shallow furrows, and have downy footstalks and ribs. The umbels are nearly, if not quite, smooth, and consist of eight to ten large and handsome rosette-coloured flowers, for which alone this plant is cultivated, the fruit, which is yellow, an inch in length, and usually elongated a little at the base, being sparingly produced, and of no value. We can discover no bracteas, and if we are not mistaken, the want of them affords the furred mark of distinction between this species and the two following.

14. P. fruticulosa. Siberian Crab-tree. Wild. n. 12. Ait. n. 8. (P. Malus 2; Ait. ed. 1. v. 2. 175.) Cratoxylon corifolium, floribus magnis; Mill. Ic. t. 269.—Leaves ovate, pointed, with shallow furrows. Umbels simple, fiddle, downy. Bracteas linear, toothed, deciduous. Styles woolly at the base.—Native of Siberia, according to Miller, who says the seeds were sent from Dauria to Peterburgh, and who had it, bearing flowers and fruit, at Chelsea, before the year 1758. This tree is now common in gardens, the fruit, which resembles a white-heart cherry in size and colour, but which is liable, in both respects, to vary, being esteemed for preserving, as well as for tarts; nor is it, when mellowed by fruit, unpleasant to eat raw. The leaves are rather more downy than the leaf, but their ribs are smooth. Flowers copious, with a light sweet scent, their colour much paler and their size smaller than P. spec-tabilis. Flower-flalks very downy. Bracteas smooth, membranous, very narrow, almost half an inch long.

15. P. bacata. Small-fruited Crab-tree. Linn. Mant. 75. excluding the reference to Miller. Wild. n. 13. Ait. n. 9. Pall. Roff. v. 1. p. 1. 23. t. 10. Gifke Ic. falc. t. 1. 12. (Cratoxylon corifolium, floribus magnis; Amn. Ruth. 195. t. 51.)—Leaves ovato-lanceolate, pointed, sharply serrated, smooth. Umbels simple, fiddle, Bracteas linear, slightly toothed, deciduous. Styles naked. Fruit smaller than the petals.—Found in low situations, about the banks of rivers, in Siberia, flowering the end of May. We received specimens from the garden of the late Right Hon. Charles Grevelle, at Paddington, in flower April 21, 1803. This differs from the last, with which some botanists have confounded it, in having broader, more acutely serrated, smoother leaves; smooth flower-flalks and styles; and a small red fruit, not bigger than a common haw. The calyx in both is deciduous, leaving a scarred hollow on the top of the fruit.

16. P. coronaria. Sweet-scented Crab-tree. Linn. Sp. Pl. 687. Wild. n. 14. Ait. n. 10. Pursh n. 7. Kalm’s Travels, English edition, v. 2. 166.—Leaves broad-ovate, somewhat lobed or angular, serrated, smooth. Flower-flalks coriaceous. Styles woolly in the lower part.—Native of woods in North America, from Pennsylvania to Carolina, flowering in May. It has long been cultivated in England, for the sake of the beauty and viole-like fragrance of its bluish-coloured blossoms, as well as for its fruit, which is as big as a small golden-rippin, extremely acid, but excellent for preserving with sugar. The leaves are distinguish from their breadth, and being slightly lobed, like some of the leaves cut down of the Hawthorn, but thrice as large.

17. P. angustifolia. Narrow-leaved Crab-tree. Ait. Hort. Kew. ed. 1. v. 2. 177. ed. 2. n. 11. Wild. n. 15. Pursh n. 8. (P. coronaria; Wangenb. Amer. 61. t. 21. f. 47.)—Leaves lanceolate-oblong, shining, with tooth-like notches; contracted and entire at the base. Flower-flalks coriaceous. Found in the low woods of Carolina, flowering in May. It resembles the foregoing species, but the fruit is very small. Corymb. This is said in Hort. Kew. to have been cultivated in 1750, by Mr. Christopher Gray. We have never examined it, nor have we any account of the fruit being downy or otherwise.

18. P. japonica. Japan Apple-tree. Thumb. Jap. 207. Wild. n. 16. Ait. n. 12. Curt. Mag. t. 692. (Malus Japonica; Andr. Repof. t. 462. Bucke; Kampf. Amoen. 844.)—Leaves elliptic-oblong, sharply serrated, very smooth. Stipulas lunate, deeply toothed. Flower-flalks somewhat aggraded. Calyx abort. Seeds numerous in each cell.—Gathered by Thumberg, on mount Fakona in Japan, where it flowers from February to April. It proves quite hardy in our gardens, into which Sir Joseph Banks introduced it in 1796, flowering at the same season, and often frequently again in autumn. When the spring is severe, the beautiful deep flecked blossoms require the shelter of a glass frame. The flem is somewhat throrny. Leaves deep green; the first that come out are short and abrupt. Stipulas on the young branches, half an inch or an inch broad. Fruit globular, we have not seen it ripe. Seeds very numerous in each cell, one above another, so that we cannot but feel some scruples as to the genus of this species.

PYRUS.

Woodv. Med. Bot. t. 79. (Malus cotonea; Ger. Em. 1452. Matth. Valgr. v. 1. 217.)—Leaves roundish-elliptical, entire; downy beneath. Flowers solitary, stalked. Calyx ferrated, reflexed.—Native of the rocky banks of the Danube. Naturalized in the hedges of Germany. Dr. Sibthorp found it wild in the northern parts of Greece, in which country it retains the ancient name *nudum.* This was among the first exotic fruits cultivated in England, where it blooms in May or June, and ripens fruit in autumn. The tree is rather spreading than tall. *Leaves* roundish, various in size; smooth and light green above; white with soft dense down beneath. *Flower-flanks* and calyx more or less woolly. *Petals* large, flesh-coloured. Fruit large, yellow, very juicy and all fragrant, but with a peculiar and very powerful fragrance. Cookery renders it mild, and to most persons highly grateful. There are three or four angular *seeds* in each cell, ranged horizontally, not, as in the latter, vertically. The Quince is supposed to be the golden apple of the Hesperides, so famous in ancient fable.

20. P. falsifolia. Willow-leaved Crab-tree. Linn. Suppl. 255. Willd. n. 18. Alt. n. 14. Pallas Roff. v. 1. p. 12. t. 9.—Leaves linear- Lanceolate, hoary, nearly entire; downy beneath. Flowers solitary, almost fertile. —Native of Siberia, America, and mount Haunts. Sent to Kew, by Pallas, in 1780. It is a hardy tree, flowering early in spring, and known by its hoary, narrow, willow-like *leaves.* The *flowers* are terminal, solitary, and nearly fertile; not axillary. Fruit pear-shaped, an inch long, brown, not at all liable to mellowed by frosts, like medlars; and even then not very good.

22. P. Aria. White Beam-tree, or White Wild Pear-tree. Ehrh. Beitr. f. c. 4. 20. Arb. 84. Sm. Fl. Brit. n. 7. Engl. Bot. t. 1858. Willd. n. 19. Alt. n. 15. (Crausetus Aria; Linn. Sp. Pl. 681. Fl. Dan. n. 301. t. 320. Aria Theophrastii; Ger. Em. 1327.)—Leaves elliptical, cut, and ferrated; white and downy beneath, with crowded parallel veins. Corymbos compound, woolly. Styles two or more.—Native of limestone rocks, or chalky hills, in most parts of Europe; not rare in the mountainous countries of England, flowering in May, ripening fruit in September. A handsome small tree, much cultivated in home plantations. The young *branches,* like the *flanks,* *stamps,* and backs of the *leaves,* are very white, with mealy or cottony down. The *leaves* vary, from white to obovate, or ovate oblong, and are pretty regularly cut, as well as ferrated, but not perforated or lobed; their veins, or side-ribs, numerous, straight and parallel; their upper side smooth. *Corymb* subdivided, many-flowered, cottony. *Petals* white, the fize of those of the Hawthorn. *Styles* two, often three, rarely four. Fruit nearly globular, scarlet, dotted, mealy and acid; its cells coriaceous rather than horned, equal in number to the *styles,* with two *seeds* in each.

23. P. intermediia. Swedish White Beam-tree. Ehrh. Beitr. f. c. 4. 20. Arb. 94. Willd. n. 20. Arb. 268. Ait. n. 16. (Sorbus alpina, folius sinuosus; Fl. Dan. n. 302. t. 301. fig. in flower only. S. hybrida; Huds. 216.)—Leaves elliptical, lobed, cut and ferrated; white and downy beneath, with rather dilant veins. Corymbs compound, woolly. *Styles* two or more.—Native of Sweden. Found by Mr. Warin, on the walls of castle *Dinas y Brân,* North Wales. *Hudson.* Specimens from the original plant prove the name as those of Ehrhart, and differ from the common *P. Aria,* only in having the *leaves* so far cut, as to be, in some degree, pinnatioid, owing to which the transverse veins are rather more dilant from each other. We can scarcely admit it to be more than a variety, as *Linnæus* made it in Sp. Pl. 681. It is his Lapland plant, Fl. Lapp. n. 199.

24. P. pinnatifida. Baltard Mountain Ash. Ehrh. Beitr. f. c. 6. 93. Exf. 145. Sm. Engl. Bot. t. 2331. (P. hybrida; Sm. Fl. Brit. n. 6, excluding the synonyms of *Hudson* and Withering. Sorbus hybrida; Linn. Sp. Pl. 684. Linn. Fil. fac. 1. t. 6. Willd. Sp. Pl. v. 2. 1008. Ait. Hort. Kew. v. 3. 204. Fl. Dan. n. 302. t. 301. fig. in fruit.)—Leaves oblong, deeply pinnatioid, or half pinnate; downy beneath. Corymbs compound, woolly. *Styles* about three.—Native of Sweden. Gathered wild, by the late Mr. J. Mackay, in rocky places on Cairn na Callich, and other mountains, at the north end of the isle of Arran. It is frequent in plantations, flowering in May, and propagated by feed. This was thought by *Linnæus* to be a mule, between *Aria,* and *aucuparia* hereafter mentioned. It nearly agrees with the former, but the *leaves* are more oblong and acute; very deeply pinnatioid, or even pinnate, in their lower part. The *flowers* and *fruit* almost agree with those of *aucuparia.* The *styles* are usually three or four.

25. P. aucuparia. Mountain Ash; Quicken, or Roan Tree. Ehrh. Beitr. f. c. 6. 94. Gaertn. v. 2. 45. t. 87. Sm. Fl. Brit. n. 5. (Sorbus aucuparia; Linn. Sp. Pl. 683. Willd. Sp. Pl. v. 2. 1008. Ait. Hort. Kew. v. 3. 204. Fl. Dan. t. 1304. Mill. Ilutr. t. 43. Engl. Bot. t. 337. S. sylvestris; Ger. Em. 1473. Matth. Valgr. v. 1. 238.)—Leaves pinnate; leaflets equal, ferrated, smooth, silky. Corymbs compound, somewhat panicked. *Styles* about three.—Native of mountainous places, in the colder parts of Europe; abundant in Scotland, Derbyshire, &c. flowering in May, and very common in domestic plantations. An elegant and very hardy tree, of flow growth, the wood being hard and tough. *Leaves* all delicately pinnate, of many pair of opposite, oblong, smooth, ferrated *leaflets,* more or less entire towards the base, with an odd one; the young ones downy beneath. *Flowers* very numerous, white, the fize of the three last, but rather more panicked. Fruit scarlet, acid and bitter, yet estable when prepared with sugar. According to Lightfoot, this tree is found generally about the Druidical circles in North Britain, and is still believed, by the superstitious Highlanders, to be powerfully efficacious against witchcraft.

PYRUS.

found it in Greece, as well as on mounts Hæmus and Athos, and in woods near Constantinople. Ray speaks of it as wild in the mountainous parts of Cornwall and Staffordshire. It is now rarely cultivated, being, though a handsome tree, yet of slow growth, and inferior in the value of its fruit to the Medlar. A solitary individual of this species now and then occurs, about ancient manions and very old orchards. It blossoms in May. The leaves are larger, and the flowers twice the dimensions of the leaf, being the size of hawk-thorn-blossoms, rather panicked than corymbose. Fruit like a small pear, reddish, above an inch long, with five cells, unfearable to the five Pyrus i its cells with two valves, like those of a Common Pear; and though only one f. d. is perfect in each cell, Gardner observed two in an early stage. This fruit, if balled before it is mellow, occasionally a most intolerable forebode at the back of the palate, lasting many hours. When ripe it is soft, brown, and agreeably acid. The name Service is evidently a corruption of Sortus.

28. P. hybrida. Mule Service Pear-tree. Willd. n. 22. Moench. Weillent. 90. t. 6. Willd. —Leaves elliptical, serrated, downy beneath; simple or pinnate, the terminal one large. Flowers corymbose. Calyx hairy. This is afforded by Prof. Wildenow, from whom we have specimens, to be a mule production, from the first species, P. arbutifolia, impregnated by the 25th, aucuparia. It retains indeed as great a resemblance to both parents as it possibly could to what are so dissimilar to each other. The simple leaves are two inches or more in length, obtuse, finely serrated; the lateral leaflets, of the compound ones, half, or one-third, as large, unequal at the base. Stipulae ovate, toothed, recurved. Flowers not much unlike the last, but their cymes somewhat smaller, with hairy, rather than downy, stalks. It is curious that the rib of each leaf, on its upper side, retains some portion of the brown glands characteristic of P. arbutifolia.

29. P. anthyllidifolia. Kidney-vetch-leaved Service-tree. —Leaves pinnate, entire; silky beneath. Corymbs axillary and terminal, of few flowers. —Gathered in the Sandwich islands, by Mr. Menzies, to whom we are obliged for specimens, under the name of Sorbus, to which, now abolished, Linnaean genus there can be no doubt that this tree belongs, though we have not seen the fruit. The leaves are all uniformly pinnate, two or three inches long, of eight or nine pairs, besides an odd one, of equal, oblong or obovate, obtuse, minutely pointed, entire leaflets, half an inch at least in length; smooth and shining above; paler and silky beneath. Stipulae lanceolate, a little hairy, deciduous.

Flower-flalks axillary and terminal, nearly the length of the leaves, downy, corymbose, though each bears but three or four flowers, which are about the size of P. aucuparia. Bracteas ovate-shaped. Calyx woolly. Styles, as far as we can see, three, hairy at the base. The leaves of this very pretty and remarkable species strikingly convey the idea, at first sight, of some kind of Anthyllis, especially A. Barba-jovis.

PYRUS, in Gardening, contains plants of the fruit-tree kind, of which the species cultivated are the common pear-tree (P. communis); the common apple-tree (P. malus); the Chinese apple-tree (P. spectabilis); the Siberian crab-tree (P. prunifolia); the sweet-scented crab-tree (P. coronaria); and the quince-tree (P. cynthia.)

With respect to the fruit, it is observed that "the wild pear, the mother of all the orchard and garden varieties, is thorny. The stipules are fuscous, white (or reddish), deciduous; the peduncles alternate; and the calyx clothed with a ferruginous wool."

There are numerous varieties, but those of most importance for cultivation are:

The little mulf, which is often termed the supreme. The fruit, when ripe, is of a yellow colour; the juice somewhat milky, and, when gathered before it be too ripe, it is a good fruit. It becomes ripe about the latter end of July, but continues good only a very short time.

The chio, or little ballad mulf, which is pretty much like the other, but smaller. The skin, when ripe, has a few streaks of red on the funicle.

The green chielard, or Haightings, which is a middle-sized fruit, that always remains green, and is full of juice when ripe. It becomes ripe in the beginning of August.

The red muscadelle, which is a large early pear, of great beauty; the skin is of a beautiful yellow, slipped with red, and the flesh has a rich flavour. It sometimes produces two crops in a year; the first about the end of July, and the second in September, or thereabouts.

The little nutlet, which is a small pear, having the skin very thin, and of a yellowish colour, when ripe. This fruit has a rich milky flavour, but does not keep long. It becomes ripe about the beginning of August.

The lady's thigh, which is here commonly called jargonelle, is of a rufset-green colour from the sun, but towards it inclining to an iron colour; the flesh is breaking, and has a rich milky flavour. It becomes ripe about the middle of August.

The Windor, which has a smooth skin, and when ripe is of a yellowish-green colour; the flesh is very soft, and, if permitted to hang but two or three days after it is ripe, grows mealy, and is good for nothing. It becomes ripe about the latter end of August.

The jargonelle, which is commonly called cuisse madame. According to Mr. Forsyth, it is certainly the true French jargonelle, and the pear that commonly goes by that name here is the real cuisse madame, or lady's thigh; it being very probable that the names have been changed, in coming to this country. This pear is somewhat like the Windor; the skin is smooth, and of a pale green colour. It is a plentiful bearer; but the flesh is apt to be mealy, if it stands to ripen, which is about the middle of August. It bears well on plantations.

The orange mulf, which is of a yellow colour, spotted with black; the flesh is milky, but very apt to be dry. It ripens about the latter end of August.

The great blanket, or bagpipe of Anjou, which has a smooth skin of a pale green colour; the flesh is soft, and full
PYRUS.

full of juice of a rich flavour. It ripens about the middle of August.

The little blanquet, which is much less than the former, of a pale colour, and the flesh tender, and full of a rich
malty juice. It ripens about the latter end of August.

The long-stalked blanquet has a very smooth skin, white, and a little coloured towards the fun, and is full of a rich
fuggy juice. It becomes ripe at the latter end of August.

The skinless or early ruffleet, which is of a reddish colour, the
skin extremely thin, and the flesh melting and full of a rich
fuggy juice. It ripens in the latter end of August.

The musk robeine, or queen's pear, (also called the amber
pear,) which is small, and of a yellow colour when ripe; it
has a rich masty flavour, and is a great bearer. It ripens
about the latter end of August.

The musk drone, which has a skin of a yellow colour
when ripe, and a rich masty taste; but is apt to grow
mealy, if left too long on the tree. It ripens about the
beginning of September.

The red orange, which is of a greenish colour, but the
tide next the fun changes to a purple colour, when ripe;
the flesh is melting, and the juice fuggy, with a little per-
frame. It ripens in the beginning of August.

The cafferette, or green muscat, is a small greenish pear,
with some specks in the skin. It is full of a rich perfumed
juice, and ripens in the latter end of September.

The great onion, brown admired, or king of summer,
which is of a brownish colour next the fun, and becomes
ripe in the beginning of September.

The musk orange, in which the skin is green, and the flesh
melting. It ripens in the beginning of September.

The averat, or August muscat, which has a smooth skin
of a whitish yellow colour; the juice is richly fugared and
perfumed, and it is esteemed one of the best summer pears
yet known. It is a great bearer, and becomes ripe in the
beginning of September.

The rose, or thorny rose, which is shaped like the great
onion pear, but much larger, of a yellowish-green colour,
but a little inclining to red next the fun. The flesh is
breaking, and the juice mealy. It becomes ripe in the
beginning of September.

The poire du puchet, which has the flesh soft and tender,
and the juice fugary. It ripens in the beginning of Sep-
ember.

The perfumed pear, which is of a deep red colour,
spotted with brown; the flesh melting, but dry, and has a
perfumed flavour. It ripens in the beginning of Sep-
ember.

The salviati, which is red and yellow next the fun, but
whitish on the other side; the flesh is tender, and the juice
fuggy and perfumed. It ripens about the middle of Sep-
ember.

The rose water, which has the skin rough, and of a
brown colour, the juice very sweet, tasting like rose-water.
It ripens in the latter end of September.

The rufflet, in which the flesh is soft and tender, and
the juice agreeably perfumed. It ripens in the latter end of
September.

The great mouthwater, which has the flesh melting and
full of juice. It ripens about the latter end of September.

The prince's pear, which has a highly-flavoured juice,
and is a great bearer, ripening about the latter end of Sep-
ember.

The summer bergamot, which is sometimes called Ham-
den's bergamot. The flesh is melting, and the juice highly
perfumed. It ripens about the latter end of September.

The autumn bergamot, which is smaller than the former;
the flesh is melting, and the juice highly perfumed. It is
a great bearer, and ripens in the beginning of October.

The summer bouchrété, which is very full of juice, and
is of a rich perfumed flavour. It ripens about the middle of
September.

The beurre rouge, (the red butter pear,) which has the
flesh very melting and full of a rich fugary juice. It ripens
in the beginning of October, and, when first gathered from
the tree, is one of the very best sorts of pears.

The dean's pear, which has the flesh melting and full of
juice, which is very cold. It is a great bearer, and ripens
in the beginning of October.

The Swafs bergamot has a melting flesh, and is full of
juice. It ripens in the beginning of October.

The long green, in which the flesh is melting and full of
juice. It ripens in the latter end of October. It is, by
some, reckoned the same with the mouthwater.

The white and grey monfieur John, which are the same;
the difference of their colour proceeding from the different
fusils and situations wherein they grow, or the stocks on
which they are grafted. If this pear be rightly managed,
there are not many sorts in the same season to be compared
with it. The flesh is breaking, and full of a rich fugary
juice. It ripens in the latter end of October or beginning
of November.

The flowered muscat, which is an excellent pear; the
flesh is very tender, and of a delicate flavour. It ripens in
November.

The vine pear, which is of a dark red colour; the flesh
very melting, and full of a clammy juice. It comes into
eating in November.

The rouletine pear, which is of a deep red colour, with
spots of grey; the flesh is very tender and delicate, and the
juice very sweet, with an agreable perfume. It ripens about
the latter end of October, but does not keep.

The knave's pear, which has the flesh fine and tender, and
the juice very much fugared. It ripens in the latter end of
October.

The marquis pear is a pear which, when it does not
change yellow in ripening, is feldom good; but if it does,
the flesh will be tender, delicate, and very full of juice,
which is fugared. It comes into eating in November.

The Crafline pear, which has the flesh extremely tender and
buttery, and full of a rich fugared juice. It is the very best
pear of the season, and comes into eating about the latter
end of December.

The Landau, or Dauphine pear, which has the flesh yellow,
tender, and melting; the juice is fugared, and a little per-
umed. It is in eating the beginning of December.

The martin fec (the dry martin,) which is almoft like the
rufflet in shape and colour; the flesh is breaking and fine;
and the juice fugared, with a little perfume. It is in eating
about the beginning of December.

The amadot, which is rather dry, but high-flavoured: it
is in eating about the middle of December.

The little lard pear, which is extremely fine; the flesh
melting; the juice much fugared, and has an agreeable masty
flavour. It is in eating the latter end of December, and is
esteemed one of the best fruits in that season.

The Louifbon (the good Lewis,) which has the flesh ex-
tremely tender, and full of a very sweet juice. It is in eat-
ing about the middle of December.

The Colmar pear, which is very tender, and the juice
greatly fugared. It is in eating about the beginning of Jan-
uary, and is esteemed an excellent fruit.

The Pechefferie, which has the flesh melting and buttery;
the juice is fragrant, with a little perfume. It is in eating about the first of January. It bears both on standards.

The virgolene pear, which is esteemed by some as one of the best fruits of the season; the flesh is melting, and full of a rich juice. It is in eating about the first of January. In dry and cold seasons it is very apt to crack, which greatly diminishes its value.

The ambrette, which is esteemed a very good pear; the flesh is quite melting, and full of sweet perfumed juice. It comes into eating about the beginning of January.

The epine d'hiver (the winter thorn pear), which has a very tender buttery pulp, of an agreeable taste, with a sweet juice highly perfumed. It is in eating about the latter end of December.

The St. Germain pear, which is a fine fruit and keeps long; the flesh is melting, and very full of juice, which in a dry season, or if planted on a warm dry soil, is very sweet. It is in eating from December till February. Mr. Forsyth remarks, that it is "an excellent bearer, when planted as a dwarf standard, and comes in succession after the same fort of pears on wall-trees are over."

The St. Aubin, which is partly full of juice, and which is often a little sharp; the flesh is tender but not buttery. It is in eating the latter end of December, and continues good two months or longer.

The Spanish bonchétien, which is a large fine pear; the flesh is breaking, and the juice sweet. It is in eating in January.

The wilting of Caflay, which is also called the small winter butter pear, is a small fruit; the flesh is melting, and the juice very rich: it is an excellent bearer on standards. It is in eating in January.

The Martin, or the lord Martin, which is a good fruit; the flesh is breaking and full of juice, which is very sweet and a little perfumed. It is in eating in January.

The winter ruflelet, which has the flesh buttery and melting, and generally full of a sweet juice. It is in eating in the latter end of January.

The franc real, or the golden end of winter, which is only esteemed for baking.

The brown beurré, which is of a reddish-brown colour on the side next the sun, and yellowish on the other side. The flesh is melting, and full of a rich juice. It ripens in October, and is esteemed an excellent pear.

The Holland bergemont, amollie, or lord Cheney's, which is a very good pear; the flesh is half buttery and tender, and the juice is highly flavoured. It keeps from the end of January till April.

The German muscat, which is an excellent pear; it is buttery and tender, and the juice is highly flavoured. It is in eating from February till April or May.

The pear of Naples, or Easter St. Germain, which is half-breaking; the juice is sweet, and a little vinous. It is in eating in March.

The winter bonchétien, which is very large; the flesh is tender and breaking, and is very full of a rich sugared juice. It is in eating from the end of March till June.

The la pastorelli, which is tender and buttery, and the juice sweet. It is in eating in March.

The St. Martial, or the angelic pear, which has the flesh tender and buttery, and the juice very sweet. It is in eating in March.

The wilding of Chaumontelle, which is melting, the juice very rich, and a little perfumed. It is in eating in January.

The brown St. Germain, which is a very fine high-flavoured pear on dwarfs and standards, and comes in after the wall St. Germain. It continues in eating from December to the end of March.

The pear d'Auch, which was introduced by the late Duke of Northumberland. It much resembles the Colmar, but is fuller towards the stalk. It is in eating from Chriftmas to April, and is, without exception, the best of all the winter pears.

The Swan's egg, which is a middle-sized pear, in a shape like an egg; it is of a green colour, thinly covered with brown; the flesh is melting, and full of a pleasant musky juice. It comes in eating in November. It is healthy, and bears well either as a standard or in any other way.

The bergamot de paque, which has also the following names: the terling, the amofelle, the Paddington, and the Tarquin. It is a fine handfeome fruit, green when gathered, and of a yellowish or straw-colour when ripe. It comes into eating about the month of April, continues till June, and makes a very handsome appearance at table.

The golden beurré, which is a very fine pear; it is a beautiful scarlet colour next the sun, and of a gold colour on the other side. The flesh is melting, and the juice high-flavoured. It ripens in October. It succeeds best, or an eal aspect, and a dry and dry soil. It is a plentiful bearer. Mr. Forsyth observes, that it "was introduced from Burgundy by the late Marshal Conway, and was first raised, in this country, at his seat of Park Place, near Henley-upon-Thames, now the seat of Lord Malmesbury."

The Williams's feeding pear, which resembles a summer bonchétien, but is more juicy, is a great bearer, and ripens in September. Mr. Forsyth says that it "will be a valuable acquisition to the market-gardeners, as it immediately succeeds the Windsor pear."

The citron de Carmes, which is a middle-sized pear, of a yellowish-green call, full at the eye; of a round shape, but tapering a little towards the stalk, which is long. It becomes ripe in July.

And the true golden beurré, which in shape and size resembles the brown beurré: but is of a reddish-brown colour next the sun. It is a very fine pear, but does not keep long. It comes into eating in October.

Mr. Forsyth gives the following selection from Anderson's and Co.'s Catalogue of Edinburgh.

Of the Summer Kinds.—The pear James, which is soon ripe, and soon rotten, has a little flavour, and is the earliest pear in Scotland.

The early carnock, which is indifferently, of a yellow colour, and bright-red towards the sun, making a beautiful standard tree.

The lemon, lady's lemon, or lady Lamont, which is indifferently good, but principally valued for coming early, and being a good bearer in common.

The green pear of Pinkey, which is a small green pear, nearly round, of a sweetish taste or flavour.

The forrow cow, a Clydesdale pear, which is a large pear with a short stalk; flat towards the eye; the colour red and yellow; the flesh tender, and marked in its colour.

The pear fanche, a Clydesdale pear, which is a big-bellied beautiful pear; the tree large, a great bearer, and fit for an orchard; but the fruit is not very good.

The grey honey, which is a pretty good pear.

The green orange pear, or orange vert, which is a very good pear.

The brave borne, chaw good, or the pope's pear, which is only an indifferent fruit.

The golden knap, supposed Scotch, which is a small summer pear, of tolerably good quality.
The early achan, an indifferent fruit; greatly inferior to the winter pear of that name.

The hanging leaf, which is the name in Clydefdale, is good and beautiful; almost round; its colour red and yellow; a delicious sweetmeat is found in its taele.

The Scots bergamot, which is a large good pear, of a yellow and red colour; the flesh tender and juicy.

The Longuenevil, which is very good, but a precarious bearer; supposed French, though not in their catalogues under that name.

The musked bonchretien, gratiola, cucumber, or Spinola's pear, which is a very good pear when grafted on a free stock; its pulp being somewhat between short and tender, with a great deal of perfumed juice, its colour red on one side, and white on the other.

And the affron pear, which is a pretty large well-shaped pear, fit for the orchard or the field.

Of the Autumnal Kinds.—The keefer, which is a Clydefdale pear, of middling size, and oblong shape, its juice agreeable.

The French carnock, which is tolerably good.

The elphin haft, or good-man pear, which is a long pear, flat towards the eye; its colour green and yellow; its flesh hard, dry, and sweet in the taele.

The Drummond, or late Scotch carnock, which is very good, if eaten before it grows mealy; its colour a bright red and yellow.

The vicar, an oblong pear, with the colour yellow, red, and striped; tender, sweet, and musked, but dry in eating.

The royal orange bergamot, which differs from the orange bergamot in being yellower, and sometimes having a faint red on one side.

The green pear of Yair, which is sweet, juicy, and melting; of a moderate size, taking its name from Yair, on Tweed-side, where it was first discovered.

The rob hind, which is very indifferent.

Le beffari, the wilding of the forest of Ileri, in Bretagne, which is a yellowish pear, of middle size, but which is indifferent.

The unicorn pear, which is of a beautiful red and yellow colour; but rather aulere in the taste or flavour.

Of the Winter Kinds.—The winter achan, which is a Scotch pear; among the best early winter pears, and equal to most of those of the French kind.

The brier buth, which is Scotch; a good pear, and will ripen in most fields; it is a small pear, of a firm substance, and sweet taste.

The Brompton park, which is a feeding pear by Jefferys of that name.

The round winter, which is a Clydefdale pear, a very excellent winter pear.

The poir portrait, or gate pear, which is proper for baking.

The la double fleur, or the double-flowering pear, which is a large flat beautiful pear, with a smooth skin, and bluish colour on one side, and yellow on the other; it is the bell to preserve, taking a beautiful red colour from the fire.

And to these the following list is added:—The Ambrosia pear, the Allton town, the autumn musk bonchretien, the bishop's thumb, the bloody pear, proper for baking, the brocas bergamot, the barland, proper for perry, the befferdi, fit for baking, the beurre du roi, the black pear, or Wortceter, fit for baking, the Britannia, the burdekin, the Doyenne, or St. Michael, the cafillac, fit for baking, the Eaier St. Germain, the Gaupe's bergamot, the golden beurre, the grey beurre, the grey good-wife, the green fugar, the green bergamot, the Huntingdon pear, the huffcap, proper for perry, the king's Catharine, the lammes, the London fugar, the muscat almain, the musk blanquet, the Oldfield, proper for perry, the orange bergamot, the pear piper, the pyrus polveria, the red admirable, the rough cap, proper for perry, the Scotch bergamot, the seven-angled, the silver-striped, the Spanish red warden, best for baking, the squaw, proper for perry, the striped verte longue, and the white beurre.

And for small gardens, where there is room only for a few trees, the following are recommended as proper for furnishing a regular succession of fruit.

Summer Kinds.—The mulk pear, the green chiffe, the jargonelle, the summer bergamot, and the summer bonchretien.

Of the Autumn Kinds.—The orange bergamot, the autumn bergamot, the Gaupe's bergamot, the brown beurre, the Doyenne, or St. Michael, and the swan's egg.

Of the Winter Kinds.—The Claflane, the Chaumontelle, the St. Germain, the Colmar, the d'Auch, the lechefraie, the winter bonchretien, and the bergamot de paquete.

And the second sort, in its wild state, is called the crab, or wilding, and is armed with thorns, as well as the wild pear. Miller mentions two varieties in the fruit of the crab, one white, the other purple towards the fun; but it is commonly yellowish-green with a tinge of red. And also a variety with variegated leaves.

There are a great many varieties of the apple, but the following are given by Mr. Forsyth as the most deserving of attention.

The Acklam's ruffet, which is a small Yorkshire apple, of a ruffet colour toward the fun, and yellow on the other side; it becomes ripe in January, and keeps till March.

The aromatic pipkin, which is a very good apple, of a bright ruffet next the fun; and the flesh has a fine aromatic flavour. It ripens in October.

The Baxter's pearmain, which is a real Norfolk apple, of a handsome size, and pale-green colour, full of small dark spots. It is a fine kitchen fruit, and will keep till April. It is also a good eating apple.

The beauty of Kent, which is a fine large apple, resembling a codlin. It is streaked with a fine red towards the fun, and of a beautiful yellow, with some streaks of red on the other side. It is a very good apple, coming into eating in September, and keeping till the latter end of April.

The belle grisedale, which is a new feeding raised at Norwich, of much beauty, and never failing to afford crops. It was first propagated by Mr. Lindley, who gave it this name. It is a handtome apple, resembling the burdoff, of a yellow colour, with red towards the fun, and a very excellent plate apple, keeping till March.

The Bell's pearmain, which is a real Norfolk apple, large and handsome; red toward the fun, and yellow on the other side. It is a fine kitchen fruit, and pretty good to et raw, keeping till Jane.

The bell pool, which is a middle-sized apple, of a pale-green colour, streaked with red towards the fun. It is a good apple, in eating from January to April.

The black apple, which is a middle-sized fruit, of a dark mahogany colour next the fun, but fainter on the other side. It is of a pleasant sweet taste, keeping till the middle of April.

The Bland's summer pipkin, which is a handtome apple, of a gold colour, and an agreeable flavour. It is a great bearer, ripe in September, and keeps till Christmas.

The Blatche's fine small table apple, which is about the size
PYRUS.

fize of a small golden pippin; red toward the fun, and green on the other side. It has a fugary taste, and comes into eating in January.

The boomeroy, which is a prettily large handsome apple, of a flat shape, and deep-red colour; and the flesh is streaked with red. It is not fit to eat raw, but will do well for cyder, or for the kitchen. It keeps till April.

The Bovey redfreak, which is a handsome apple, of a flatish shape, beautifully streaked with a bright red next the eye, which is small, and of a yellow colour about the fruit. It keeps till the latter end of October.

The broad-eyed pippin, which is a fine large apple, with a very large eye; the colour is a greenish-yellow, with a little red toward the fun. It is a good apple, and keeps till May.

The brandy apple, which is about the fize of a golden pippin, flat-shaped, and of a yellowish rufflet colour. It is of a pleasant flavour; comes into eating in January, and keeps till March.

The broadf, or queen's apple, which is a beautiful fruit, red next the fun, and of a fine yellow on the other side. It is a very fine apple; in Mr. Forfyth's opinion, next in perfection to the golden pippin, and about the same fize. It is of a good flavour; ripening in January, and keeping till March.

The carnation apple, which is a beautiful middle-fized fruit, finely streaked with red. It is ripe in January, and keeps till May.

The Carbury pippin, which in fize and shape resembles the French crab, and is of a deep green colour. It is a good baking apple, keeping till March.

The caraway rufflet, which is a handsome rufflet-coloured apple, about the fize of a nonpareil.

The calville, red and white, which are good apples, and of a vinous taste. Some have a red and some a white pulp, the white being reckoned of a mott delicious taste. They are in eating in September, and the following month.

The cat's-head, which is a large oblong apple, of a greenish-yellow colour, with a little brownish-red next the fun; sometimes the colour inclines to a rufflet. It is a good baking apple, and is in eating from October to December.

The cockagee, which is a conical-shaped middle-fized apple, red on that side next the fun, and of a fine yellow colour on the other. If properly managed, the fruit keeps till February. It is a famous cyder apple, and also bakes well.

The codlin, which is generally the first apple that is brought to market. Its fruit is so well known that it needs no description. It is in eating from July to December; and is good either for baking or boiling.

The Cornish nonpareil, which is rather under the middle fize, is a little flattened, and of a rufflet colour. It is a very good apple, and keeps till the middle of March.

The Cornish pearmain, which is of a middling size, and long shape; of a dull-green colour on one side, and rufflet on the other. It is a very good apple, and keeps till the latter end of April.

The Court-of-Wick pippin, which is described by Mr. Billingbly, in his "Survey of Somersetshire," as "the favourite apple, both as a table and cyder-fruit, taking its name from the spot where it was first produced. It originated from the pip or seed of the golden pippin, and may be considered as a beautiful variety of that fruit. In shape, colour, and flavour, it has not its superior: the tree is large, handsome, and spreading, and a very luxuriant bearer. On the whole, it cannot be too strongly recom-
mended." It is larger than the golden pippin, of a yellowish-green colour, and a little tinged with red next the fun. It comes into eating in January.

The Cockles pippin, which is a handsome oval-shaped fruit, below the middle fize, of a rufflet colour, mixed with yellow and red. It keeps till April.

The corpender, or hanging body, which is a very large apple, and has a red call on the side towards the fun; but is pale on the other side. It takes its name from always hanging downwards; and comes into eating in September.

The Dalmahoy pippin, which is about the fize of a golden pippin, of a green colour, and a little streaked with red towards the fun. It has a tolerably good flavour, rather sharp; and is in eating from September to February.

The Dimock's red, which is under the middle fize, of a fine red colour, intermixed with a little yellow, on the side from the fun. It is ripe in January, and keeps till March.

The Dredge's feeding, which is a fine large apple, streaked with red next the fun, and of a yellowish-green on the other side. This is an excellent kitchen apple, of a pleasant taste, and keeps till the latter end of January.

The Dredge's beauty of Wilts, which is a beautiful apple, of a good fize, and one of the finest yet known in point of general utility. It is of a fine bright yellow colour, spotted with red towards the fun; and has an excellent vinous flavour. It is good either for the table or baking, and keeps till March.

The Dredge's rufflet, which is a small apple, of a greenish-rufflet colour, and of a pleasant flavour. It is ripe in November, and keeps till Midsummer.

The Dredge's white lily, which is a fine apple, of an exceeding high flavour, and keeps till March.

The Dredge's fair maid of Wiltshire, which is a fine middle-fized apple, of a yellowish-green colour, with some rufflet next the fun, of an excellent flavour. It is a great bearer, and is in eating from Christmas to Easter, being an excellent dessert apple.

The Dredge's queen Charlotte, which is a beautiful middle-fized apple, of a gold colour, with red towards the fun. It is of an excellent flavour, comes into eating about Chrifmas, and keeps till February.

The Dredge's faene, which is a good fixed apple, red towards the fun, and streaked like the Ribton pippin on the other side. It is a most excellent apple, being in eating from Easter to Midsummer.

The dumpling apple, which is a handsome apple, and rather above the middle fize, flat shaped, and of a greenish-yellow colour, with some faint streaks of red. It keeps till March.

The Dutch queening, which is a large apple, somewhat resembling the cat's-head in shape. The colour is red next the fun, and green on the other side, with sometimes a little red. The fruit is fit only for the kitchen, and for making cyder. It is ripe in January, keeping till the end of March.

The Elton's yellow kernel, which is a handsome middle-fized apple, of a yellow colour. It is a good table apple, being in eating from January to March.

The English rennet, which is a handsome apple, beautifully streaked with red, but darkest towards the fun; of a tolerable flavour, but apt to grow mealy when kept too long. It keeps till the middle of May.

The embroidered apple, which is pretty large, and the stripes of red very broad, from which circumstance it takes its name. It is commonly used as a kitchen apple, becoming ripe in October.

The everlasting striped apple, which is below the middle fize,
fize, of a conical shape. The colour is a striped green towards the footstalk, and red towards the eye.

The famous, which is a pretty large apple, of a beautiful dark red, with a little yellow on the side from the fun. Its flesh is very white, and full of a rich juicy juice; coming into eating about the latter end of October. It was introduced from Canada by Mr. Barclay of Brompton.

The fenouillet, ou pomme d’anis, the fennel or anise apple, which is a middle-sized fruit, of a grey colour; the pulp is tender, and has a spicy taint, like aniseed. It becomes ripe in September and October.

The flower of Kent, which is a large handsome apple, of a yellow colour, and pretty good flavour. It keeps till the middle of April.

The fox-whelp, which is a small apple, stalked with red. It is ripe in January. It is a cyder apple.

The Franklin’s golden pippin, which is a handsome middle-sized apple, of a conical shape and gold colour, beautifully marked with dark spots. The fruit has a fine aromatic flavour, and deserves the first place at the table; but it is a very fly bearer. It comes into eating about the middle of November.

The French crab, which is a large handsome apple, of a deep green colour, with a little red next the fun. It will keep all the year; is a good baking apple, and, if the summer be warm, pretty good for eating, and is a great bearer.

The French coquin, which is a pretty large apple, of a conical shape, and green colour, with red towards the fun, coming into eating in January.

The Pearmain, which is of the shape and fize of a nonpareil. It is of a beautiful scarlet next the fun, and of a golden yellow on the other side. It makes a fine show at table, and keeps till the latter end of February.

The French Spaniard, which is a large apple, in form of a hexagonal prism with the edges a little rounded, and of a yellowish-green colour; it is pretty good, and keeps till the latter end of April.

The French or white rennet, which is a large fruit, of a yellowish-green colour, with some grey spots. It has a fugatory juice, and is good either for eating or baking.

The Gargey pippin, which is a handsome conical-shaped apple, under the middle fize, of a greenish-yellow colour, with a little red towards the fun. This is a pretty good apple, and keeps till May.

The giglisflower, which is a fine handsome apple, red towards the fun, and of a yellowish-green on the other side, having a fine flavour, and keeping till the latter end of March.

The golden rennet, which is a beautiful apple, a little flattened; of a fine red colour towards the fun, and yellow on the other side. It is a good eating apple, and keeps till February.

The golden rennet, which is a fine middle-sized apple, of a golden rennet colour, from which it takes its name. It is a good apple, and keeps long.

The golden pearmain, which is a fine apple, above the middle size, of a fine deep red towards the fun, with a little yellow on the other side; when much exposed to the sun it is sometimes red all over.

The golden Mundi, which is a fine handsome apple, beautifully streaked with red; of a good flavour, excellent for baking, and will keep till January. It is a good fauce apple.

The golden Glouster, which is a handsome middle-sized apple, of a flat shape, and gold colour, with red toward the fun. It is a good apple, and keeps till March.

The golden Cider, which is a handsome though rather small apple, of a fine gold colour, sometimes inclining to a ruflet. It has a plesant flavour.

The golden pippin is well known; and the French own it to be of English origin. It is almost peculiar to this country; for there are few countries abroad where it succeeds well. It is yellow as gold; the juice is very sweet; the skin (especially where exposed to the sun) is often freckled with dark yellow spots. It is certainly the most ancient, as well as the most excellent, apple that we have. It ripens in October, and keeps through the winter. It has several sub-varieties.

The Godolphin apple, which is a very handsome large fine fruit, streaked with red on the side next the fun, and of a yellowish colour on the other side. It is in eating from the latter end of September to December.

The green dragon, which is a fine large apple, of an excellent flavour, and pale-green colour. It is rather too large for the table, and is therefore mostly used as a kitchen apple. It keeps till March.

The great or large ruflet, which is a middle-sized fruit, of a ruflet colour, with a little dark-red toward the fun. A pretty good apple, and keeps till April.

The Grendleton pippin, which is a large angular-shaped apple, of a greenish-yellow on the other side. It is of a fine flavour, and is in eating from January till March.

The Grumman’s pippin, which is about the fize and shape of a golden pippin; of a dingy-green colour next the fun, and of a dull yellow on the other side. It is ripe in January, and keeps till April.

The Hasloe crab, which is a yellow-coloured conical-shaped apple, below the middle fize. It is ripe in January; but is only fit for making cyder, or for baking.

The half-door, which is a fine large apple, of a flat shape, beautifully streaked with red toward the fun, and of a greenish-yellow on the other side. It is of a fine flavour, and is in eating from January till March.

The Hallingbury, which is a large flat-shaped apple, with large ridges from the base to the crown. It is of a beautiful red toward the fun, and of a yellowish colour on the other side and towards the eye.

The Hampshire nonfuch, which is a pretty large well-shaped apple, of a greenish-yellow colour, streaked with red. It keeps till the latter end of November.

The Harvey’s ruflet, which is so called in Cornwall, is a large ruflet-coloured apple, with a little red toward the fun. It is a famous kitchen fruit, and tolerably good raw, with a pulpy flavour.

The Holland pippin, which is a middle-sized apple of a flattish shape. Its colour is yellow, in some places inclining to green, with, sometimes, a little red toward the fun. It is a pretty good apple, keeping till the middle of April.

The hollow-eyed pippin, which is a middle-sized apple, of a yellow colour, beautifully spotted with red toward the fun; and the eye is pretty deep. It is a good sharp-flavoured apple, keeping till the middle of May.

The hollow-eyed rennet of Cornwall, which is a handsome flat-shaped apple, under the middle fize, of a greenish-yellow colour, sometimes intermixed with ruflet. It is of an excellent flavour, and keeps till April.

The hedge apple, which is a new fruit, of middle fize and handsome conical shape, red toward the fun, and of a straw colour on the other side. It is of a tolerably good flavour, and keeps till the latter end of April.

The hoghead apple, which is a small red fruit; the flesh is red, and the taines amber. It is a cyder apple, becomes, ripe in January, and keeps till March.
The Hubbard's, or the ruflet pearmain, which is a real Norfolk apple; and, though not handsome, is one of the best table apples. It is of a dark russet colour, becomes ripe in January, and keeps till April.

The John apple, which is a middle-sized handsome fruit, of a green colour, with a little red toward the fun; the footstalk being very small. It is an excellent cyder and baking apple, from Devonshire; it is of an excellent flavour, and keeps till March.

The Isle of Wight pippin, which is a handsome middle-sized apple, of a greenish-yellow colour.

The juneting, or jenneting, which is a small yellowish apple, red on the side next the fun. It is a pretty fruit for early variety, and ripens about the latter end of June or beginning of the following month.

The kernel redtbreak, which is of a greenish-yellow, with broad streaks of a dark-red all over it, and a yellow ground finely speckled with red next the fun.

The kernel pearmain, which is a small handsome apple, red toward the fun, and of a yellowish-green mixed with red on the other side. It is of a good flavour, keeping till the middle of May.

The Kentish pippin, which is a good sized apple, finely streaked with red. It is of a fine flavour, comes into eating about Christmas, and keeps till February.

The Kentish nonpareil, which is a handsome flat-shaped apple, of a light russet colour, inclining to red toward the fun. It is of a good flavour, and keeps till May.

The king of the pippins, which is a middle-sized apple, of a fine gold colour, a little streaked with red towards the fun. It is ripe in January, and keeps till the latter end of March, when it becomes mealy.

The king apple, which is a middle-sized apple, of a conical shape; and its colour is that of a beautiful red intermixed with a little yellow on one side. This apple is of a pleasant sugary taste, and keeps till the latter end of April.

The Kirke's feeding, which is a beautiful apple of a fine red colour towards the base, and yellow towards the eye. The footstalk is slender, and the eye large.

The Kirke's scarlet pearmain, which is a handsome middle-sized apple, of a beautiful red toward the fun, and a little yellow on the other side; becoming ripe in January.

The Kirke's scarlet admirable, which is a good apple for baking, and of a beautiful scarlet colour, is in eating about the month of January.

The Kentish fill-baskets, which is a species of codlin, of a large size, and generally used for baking. It is in eating from August to October.

The Kirton or crack'd pippin, which is a middle-sized apple, of a greenish-yellow colour, with little dark spots. The coat is generally rough towards the footstalk. It is a good apple for the table, coming into eating in September.

The lady's finger, which is an excellent table apple, of a conical shape; red next the fun, and of a yellowish cast on the other side, having a sweet pleasing flavour, and keeping till May.

A large ilyre, which is a handsome cyder apple, of a yellow colour, with a little red next the fun. It becomes ripe in November.

The Lisbon pippin, which is a handsome middle-sized apple, of a flat shape, a fine red toward the fun, and a reddish-yellow on the other side. The flesh is firm, and has a sharp pleasing taste. It comes into eating in November.

The Loan's pearmain, which is a large oval-shaped apple, of a dull green colour intermixed with a brownish-red, deepset next the fun. It is a pretty good table apple, of a sharp taste, ripening in September, and keeping till May, but is apt to grow mealy.

The London pippin, or five-crowned pippin, which is a fine large apple, of a green colour, streaked with red toward the fun. It resembles the Ribston pippin, but is larger. It has a pretty agreeable taste; and will come into eating about the latter end of November. It is good for the kitchen and table; and a most abundant bearer. It keeps till the middle of April.

The le calvill d'automne, the autumn calville, which is a large fruit, of an oblong figure, and of a fine red colour toward the fun, having a vinous juice, and is much esteemed by the French.

The long lattier, which is a middle-sized apple, of an angular shape, and fine yellow colour, with a beautiful red next the fun. It is of a tolerable flavour, and keeps till the middle of May, but is apt to become mealy.

The lemon pippin, which is a handsome oval-shaped apple, of a gold colour. It is of a fine flavour, and will keep till the beginning of March.

The long feam, which is a large angular-shaped baking apple of a pretty good flavour, with light green colour. It keeps till the latter end of January.

The lord Cheney's green, which is a middle-sized Yorkshire apple, resembling the Yorkshire greening. It is of a dark green colour, with a little of a chocolate colour next the fun. It is a baking apple, and keeps till the middle of May.

The lord Arundel's apple, which is large, of an angular shape; the colour is green, with a little dingy red towards the fun. It is from France, and good for flame, keeping well.

The lord Camden's rennet, which is a good-sized feeding, of a yellow colour, with a little brownish-red next the fun. It is a good flavoured apple, and keeps till March.

The Lucas's pippin, which is a handsome, middle-sized, cylindrical-shaped apple, of a beautiful orange colour. It is a pretty good fruit, and keeps till the latter end of April.

The maiden's blush, which is a small apple, of a dark mahogany colour next the fun, but paler on the other side, and sometimes of a greenish cast. The fun is auliere, and of course this fruit is not fit for the table; but does very well for baking, or for cider. It keeps till the beginning of March.

The Mansfield tart, which is a large Nottingham apple, but most known in Yorkshire. It is handsome, of a green colour, having a little call of brownish-red, with dark spots next the fun, being a baking apple, and keeping till February.

The May gemet, which is rather under the middle size, of a greenish-yellow colour, slightly streaked with red next the fun. It keeps till April.

The major Hemming's apple, which is a handsome middle-sized fruit, of a light green colour, with a little brownish-red towards the fun. It is an excellent apple.

The margil, which is an excellent apple, about the size of a nonpareil. It is of a red colour, with some yellow on one side; continues in use from November to the latter end of March; and is often sold in the London markets for a nonpareil.

The Margaret apple, which is a fine and beautiful fruit, yellow, striped with red, of a delicate taste, sweet scent, and generally eaten off the tree. It is ripe in August.

The Minchall crabb, which is a handsome middle-sized Lancashire apple, of a yellow colour, with some brown spots.
PYRUS.

It is common in the Manchester markets, and keeps till April.

The montrous rennet, which is a very large apple, turning red towards the fun, and of a dark green on the other side. It is generally preferred on account of its magnitude, as the flesh is apt to be mealy. It becomes ripe in October.

The mother rennet, which is rather under the middle size, of a greenish colour, with a little blush towards the fun. The eye is large and deep, and the footstalk small.

The New-England pippin, which is a large angular-shaped apple, of a green colour, with a little brownish-red towards the fun. It has a pretty good flavour, and keeps till March.

The Newton pippin, which, according to Mr. Forsyth, is an American apple, but said to be originally from Devonshire. It is a fine large apple, of a greenish-yellow colour and red, with dark spots next the fun. When much exposed, it is of a beautiful red towards the fun, and of a golden colour on the other side. It has a fine flavour when not kept till it is too ripe, as then it becomes mealy. It is in eating from November to January.

The new red mott, which is a fine large apple, of a pale red towards the footstalk, and of a greenish colour towards the eye. It is a cider apple, and fit for baking.

The new red pippin, which is a beautiful middle-sized apple, of a dark red colour, with a mixture of yellow on the side from the fun. It keeps till March.

The nonfuch, which is a good bearer, and very fit either for the table or kitchen; the cooks, however, complain that it makes but a very small proportion of sauce. It is ripe in September and October.

The nine-square, which, according to Forsyth, is a Gloucestershire apple. It is a large angular-shaped fruit, of a fine red towards the fun, and yellow on the other side, with a small mixture of red, keeping till April.

The Norfolk colman, which is a middle-sized apple, of a mahogany colour towards the fun, and a dark green on the other side. It keeps till August.

The Norfolk beesh, which is a good-sized apple, rather flattened, of a deep red colour towards the eye, but paler towards the footstalk.

The Norfolk paradise, which is a large apple, of a dark red colour towards the fun, and green on the other side. It is a nice baking apple, and of a tolerable flavour for eating. It keeps till the middle of May.

The Norfolk florine, which is a pretty large apple, of a dark red colour towards the footstalk, and green towards the eye. It is of a pleasant sharp flavour, being in eating from the latter end of January to the latter end of April.

The northern greening, which is a fine oblong apple, full at the footstalk, of a pale green colour, with a little red towards the fun. It is nearly of an equal size from the base to the crown, and has a fine flavour, being ripe in January.

The nonpareil, which is a fruit deferredly valued for its brillen of its taste. It is seldom ripe before Christmas, and, if well preferred, will keep till May. It is justly esteemed one of the best apples that have been yet known.

The oak peg, or oaken pin, which is an oval-shaped middle-sized fruit, of a green colour striped with white. It is very full towards the footstalk, which is small, keeping till June.

The old English pearmain, which is an oval-shaped apple, of a middle size, and fine red colour, with a little yellow towards the eye. It is of a pleasant sweet flavour; and is in eating from January to March.

The old red mott, which is a fine large apple, somewhat resembling the new red mott, both in shape and colour, with the addition of dark red spots towards the footstalk.

The old red pippin, which is a middle-sized apple, red towards the fun, and of a greenish colour on the other side. It is a good apple, and keeps till March.

The orange pippin, which is about the size of a large golden pippin; of a beautiful gold colour, with a little pale red towards the fun. It is a handsome apple, of a good flavour, and makes a fine appearance at table, being in eating in October, and keeps till March, but gets flat in the table when too long kept.

The Orleans pippin, which is a small flat-shaped apple, of a dark red colour, resembling the Orleans plum.

The paradise pippin, which is a handsome middle-sized apple, of a reddish cast. It comes into eating in October, but will not keep. It grows mealy when too ripe.

The paxton, which is below the middle size, of a conical shape, and of a greenish-yellow, or light green colour. It is ripe in January.

The Pike's nipple, which is a middle-sized longish-shaped apple, ruffet about the footstalk, yellow towards the middle, and of a brownish-red about the eye. It is a very firm fruit, of a sharp acid flavour, being much esteemed for baking. It ripens in October, and will keep till April.

The pignanette, which is rather below the middle size, of a conical shape. It is of a pink colour, pretty dark towards the fun.

The Pearmain's pippin, which is a nice apple, about the size of a large golden pippin, of a yellowish colour, and the form a little flat. In Devonshire, according to Mr. Forsyth, they put these pippins into the oven just after the bread is drawn, laying a weight over them to flatten them, in the same manner as they do the beech in Norfolk, and bring them to table as a sweetmeat. It is a very good dessert-apple, and keeps till March.

The pomme grise, which is a fine apple, from Canada, of a flattish form, and ruffet colour, striped beautifully with red. It ripens late, and keeps till March. It is an excellent eating apple.

The pomme d'api, which is much valued for its colour, being of a bright red. The tree is a good bearer, and the fruit is not subject to be shaken with high winds. The fruit should be suffered to hang on the tree till October or November, if the frost do not set in. It comes into eating in February and March, and keeps long; but is more admired for its beauty than its flavour, or fineness of table.

The pomme violette, the violet apple, which is a pretty large fruit, of a pale green, striped with red towards the fun. It has a very fragrant juice, and a flavour of violets, from which it takes its name. It ripens in October, and continues in eating till February, or later.

The pomroy, or king's apple, which ripens nearly as soon as the juniper, and though not so beautifully covered, is larger and much better taffet. It has a sub-variety, which is a winter apple.

The pound pippin, which is a large handsome apple, of a greenish colour, and is good for baking. It becomes ripe in January.

The poor man's profit, which is a dingy coloured oval-shaped apple, below the middle size. It is raised freely from cuttings; and keeps till January.

The queening, which is from Gloucestershire, is a large apple, of irregular shape, having large ridges from the base to the crown. It is of a dark red, but deepest towards the fun. It is a good cider apple, and bakes well, keeping till the latter end of November.

P 2
**PYRUS.**

The queen's kernel, which is a fine apple, above the middle size, of a deep red colour. Covered very thick with small white specks. It is a tolerably good apple, and keeps till the latter end of April.

The queen's pippin, which is a small handomely apple, of a yellow-green colour, sometimes inclining to red on the side next the sun. It is a fine-flavoured apple, very fit for the table, coming into eating in January, and keeping till May, but is apt to grow mealy when kept too long. Mr. Forfith says, "the tree never grows to the height of other apple-trees."

The quince-apple, which is a middle-sized fruit, of a yellow colour, with a little red towards the eye. It is of a pleasant sharp flavour, ripe in January, and keeps till April.

The Ramborn, which is a large fruit, of a fine red next the sun, and striped with a yellowish-green. It ripens about the middle of September.

The red pearmain, which is smaller than the pearmain in general. It is of a deep red, with a little yellow on one side. A pleasant sweet apple, and keeps till the middle of April.

The red-splendour, which is a handsome middle-sized apple, beautifully streaked with red. It is a good cider apple, becoming ripe in January.

The red-spotted, from Longleat, is from the Dorset-shire red-spotted, is a beautiful apple, of a yellow colour, streaked with red, particularly next the sun. Forfith says, it is sold in the Bath and Bristol markets in the latter end of September, and beginning of October. It is a pretty good apple, but does not keep long.

The red-bag, which is a beautiful large Herefordshire apple, of a longish shape, streaked all over with a dark red; and is in eating about the middle of October.

The red mulch, which resembles the old red mulch in shape; but is of a dark red colour towards the sun, and yellow on the other side. It is ripe about the middle of November.

The rennete grife, which is a middle-sized fruit, of a grey colour next the sun; it is a very good juicy apple, of a quick flavour, and ripens about the latter end of October.

The red sheep, which is a small round apple, red towards the sun, and of a greenish-yellow on the other side. It is a good bearer, according to Forfith, "and much esteemed among the country people of Cornwall, for making a kind of tart or pie. one of their dainties at Christmas." It is a pretty good table apple, and keeps till March.

The Ribston pippin, which is a fine apple, from Ribston Hall, near Knareborough, in Yorkshire. It is a little streaked with red towards the sun, and yellow on the other side, being one of the best apples for eating and keeping, and continues in use from the end of October till April. It bears very well as a dwarf, and no gardener should be without it.

The Ribston's pippin, which is about the size of a golden pippin, of a green colour, and partakes of the flavour both of a golden pippin, and a nonpareil. It keeps till May.

The royal George, which is a fine large apple, of a beautiful yellow on one side, and green on the other. It is a good apple, and keeps till June: but then grows mealy.

The royal nonpareil, which is a handsome apple, of a flattish shape, with a small footstalk and fine eye. It is about the size of a common nonpareil, of a green colour, with red towards the sun. It is ripe in January, and keeps till the latter end of March.

The royal pearmain, which is a fine large apple, beautifully streaked with red. It is ripe in January, and keeps till March, being a pretty good apple.

The royal rutlet, or leather-coat rutlet, which is a large fruit, and one of the best kitchen apples that we have. It is also a pleasant eating apple, and a good bearer, being in use from October to April.

The rutlet pippin, which is of a rough rutlet colour towards the sun, and of a green colour, sometimes inclining to yellow, on the other side. It is a good keeping apple, and fit either for baking or eating raw. It is ripe about the beginning of February, and keeps till March.

The summer pearmain, which is striped with red next the sun; the flesh is soft, but soon turns mealy; so that it is not much esteemed. It is in eating in August and September.

The silver pippin, which is a handsome middle-sized conical-shaped apple, of a yellow colour, with a faint blush towards the sun. The flesh is firm and very white, and of an excellent flavour. It keeps till the middle of May, or later.

The seek no farther, which is a handsome apple, rather above the middle size, of a pale green colour, a little streaked with red. It is of a pleasant though not very high flavour; and is in eating from January to May; but is apt to be mealy when kept longer than the beginning of April.

The Sykehouse, which is a handsome middle-sized apple, from Sykehouse in Yorkshire, of an Orange colour towards the sun, four times inclining to red, and yellow on the other side. This is a fine eating apple; ripe in January, and keeps till April.

The pine pippin, which is of a green colour, streaked with red towards the sun. It is of a sharp taste, and is in eating from January till the middle of May.

The Stoup codlin, which is a large handsome apple, of a pale green colour, with a little red towards the sun. It is a baking apple, of a pleasant taste, and keeps till May.

The striped nonpareil rutlet, which is a handsome apple, of a greenish-rutlet colour, with a little brownish-red towards the sun. It is about the size of a large nonpareil, is ripe in January, and keeps till March.

The spice apple, which is a handsome middle-sized angular-shaped apple, of a yellow colour, and a pleasant flavour. It is ripe in January, and keeps till March.

The Skerm's kernel, which is a conical-shaped middle-sized apple, beautifully streaked with red, deepest towards the eye, and having a good deal of yellow towards the footstalk. It is ripe in January, and keeps till March.

The spice rennet, which is a handsome apple, below the middle size, red towards the sun, and yellow on the other side.

The Spanish pearmain, which is a middle-sized oblong apple of a carmine colour, and dark-red towards the sun. It is a pretty good apple, and keeps till the beginning of May.

The Spanish onion, which is a handsome round apple of a rutlet colour, with a dull red towards the sun. This apple, which is rather below the middle size, is very good for dessert, keeping till March.

The Sharp's rutlet, which is below the middle size, of a brownish-red colour towards the sun, and a pale-green on the other side. It is shaped like the fruitlet of a cone; is of a pretty good flavour; and keeps till May.

The Spencer's pippin, which is a middle-sized apple, of a yellowish colour, with many dark spots, being a baking apple, and keeping till the middle of May.

The Turstion, which is a conical-shaped yellow apple, with sometimes a little blush towards the sun. It is an excellent
excellent sauce apple, and bakes well, being of an agreeable taste, but too large for the table. It will keep till February.

The transparent apple, which was introduced from St. Petersburg; but it is more curious than useful: a tree or two, therefore, will be sufficient for a garden. It ripens in September or October.

The Trevoird rennet, which is a small handfome russet-coloured apple, of an excellent flavour, and will keep till May.

The white corpendu, which is a middle-sized long-shaped apple, of a yellowish colour. It is a good eating apple, and ripens in January.

The ward apple, which is a beautiful flat-shaped apple, rather below the middle size, of a fine red towards the eye, and of a yellowish-green towards the footstalk. It is a sharp flavoured fruit, and keeps till June.

The Wheeler's rullet, which is of middling size, the flesh firm, and of a quick acid flavour; it is an excellent kitchen fruit, and keeps long. It ripens in October.

The wine rullet, which is a middle-sized conical-shaped apple, of a dark rullet colour, and sharp flavour. It keeps till the latter end of April.

The Wheeler's extreme, which resembles the pomme grise, and is about the size of a nonpareil. It is a flat-shaped apple, beautifully clouded with red on a yellowish-russet-ground; is of an excellent flavour, and keeps till April.

The white mout, which is a middle-sized handfome apple, of a greenish-yellow colour, with a little red towards the fun; the flavour is rather tart, but agreeable. It is ripe in January.

The Whitmore pippin, which is a good-sized handfome apple, streaked with red towards the fun, and of a pale-yellow on the other side. It has firm flesh, of a tolerably good flavour, and is in eating from November to the latter end of April, or later.

The Wiltshire cat's-head, which is a large handfome apple, red towards the fun, and green on the other side. It is a very fine baking apple, and of a good flavour, being ripe in January.

The winter pearmain, or Herefordshire pearmain, which is of a fine red next the fun, and dripped with red on the other side; the flesh is juicy, and keeps well. It is fit for use in November, and, if properly managed, will keep till the latter end of March.

The winter pomroy, which is a pretty large conical-shaped apple, of a dark-green colour, a little streaked with red towards the fun. The coat is rather tough. It is a good baking apple, keeping till January.

The winter box apple, which is a middle-sized fruit, of a light green colour, and keeps till February.

The woodcock, which is a good-sized apple, of a dark red next the fun, and paler, with a little mixture of yellow, on the other side. It is ripe in January, and keeps till March, being a good cider apple.

The Wright's nonpareil, which is a Salopian apple, being a great bearer, of a good size, and a little flattened. It is a good kitchen apple, and keeps till June. The tree is smaller in size than most other apple-trees.

The Yorkshire greening, which is a good-sized flattened apple, of a dull-red colour, with a little green towards the eye. It keeps till August, or often later.

The sorts of apples advised for a small garden are the following: the juneting, the golden pippins, the nonfuch, the Ribiton pippin, the nonpareils, the queen's apple, the Sykehousse, the golden rennet, the aromatic pippin, the grey Leadington, the scarlet pearmain, the lemon pippin, the pomme grise, the French crab, and different sorts of russetins and codlins, for baking.

But there are other varieties and sub-varieties that may be equally valuable with many of the above sorts.

Of the sixth sort there are the following varieties: the pear quince, with oblong-ovate leaves, and an oblong fruit lengthened at the base; the apple quince, with ovate leaves and a rounder fruit; the Portugal quince, with obovate leaves, and an oblong fruit, which is more juicy and less harsh than the others, and therefore the most valuable.

The quince is a very beautiful tree when in flower, as well as when the fruit is ripe in the autumn, and was cultivated in this country at an early period. According to Mr. Forfith, the best sort for planting in the fruit-garden is the Portugal, being the fittest for baking or stewing. It is of a fine purple colour when drenched, and is much better for marmalade than any of the other sorts. The oblong kind, and the apple quince, are also planted in these situations, and other sorts are employed in the shrubberies for producing variety. The above sorts are likewise valuable for mixing with apples in making pies, puddings, &c. as they add a quickness to the flavour when flat.

Method of Culture in the Pear Kind.—These trees are raised by grafting and budding upon any kinds of pear stocks; occasionally upon quince stocks; and sometimes upon white-thorn stocks; but the first sort are preferable for general use to have large trees, and the second for moderate growers.

The numerous varieties of these trees having been first accidentally obtained from seed, and as these seedlings rarely produce the same fruits again, the approved kinds are continued and increased only by grafting or budding upon stocks raised from the kernels of the kinds just mentioned. In order to restrain the growth of these trees, white-thorn stocks have also been used; but these are not so generally successful, and are almost in total disuse in the nurseries: of course pear stocks are proper for general use, for principal large trees, both for walls, espaliers, and standards; and quince stocks for smaller growths. For raising the stocks, the seeds or kernels of the different sorts should be sown in the latter end of autumn, as November, or December, or early in the spring, in beds of light earth, covering them near an inch deep; they come up in the spring; and in autumn, winter, or spring following, the strongest should be planted out in nursery-rows to remain for grafting and budding, for which, after having from one to two or three years' growth, they will be of proper size.

The operations of grafting and budding should be performed in the usual method; the former in the spring, and the latter in summer. (See GRAFTING and BUDGING.) For this purpose the grafts and buds should be procured from such trees as produce the finest fruit of the respective sorts; those designed as dwarfs for walls, espaliers, or standard-dwarfs, being grafted or budded near the bottom; and in those for half or full standards, the stocks may either be previously trained up from three or four to seven or eight feet high to form a stem, then grafted near the top, or be grafted low-in the stock, like the dwarfs, and the first main shoot trained for a stem the above height: the grafted trees, both dwarfs and standards, should be the same year, but the budded ones not till the spring after: and when their heads are two years old from the grafting and budding, they may, if thought proper, be planted out for good, or remain longer in the nursery, as may be found convenient.

The dwarfs for walls, espaliers, &c. whether they remain longer in the nursery, or be transplanted at a year old into the garden, should have the first shoots from the graft or bud.
bud, when a year old, headed down in March to five or six eyes, to force out a proper supply of four, six, or more lateral branches near the ground, to fasten the wall or efpaliers with basers quite from the bottom, the readily producing others to cover the upper part.

Standards, fuppoing them to be grafted on high flocks, may either be headed near the top of the flock, or permitted to run up, as the cafe may require, fo that if fhortened it will force out laterals near the head of the flem, and form a more spreading full head; and if fuffered to run up with the firft shoots entirely, they form higher and generally more upright heads in the end. Such standards, however, as are grafted or budded as low in the flock as for dwarfs, muff have the firft shoot trained upright at full length, six or seven feet high for a flem: if for full standards, they may either be topped at fix feet height, to force out laterals near that part to form a spreading head, or fuffered to run and branch in its own way to form a more erect and higher head.

The headed trees, both dwarfs and standards, on being cut down in the spring, foon branch out from all the eyes immediately below; when care should be taken during the fummer to trim off all shoots from the flem, fuffering all the top shoots to remain entire; when they will form handfome beginning young heads by the end of fummer, and in autumn, winter, or spring following, may be finally planted out into the garden, &c.

When from neceffity they are retained longer in the nurfery, the whole should have proper pruning to reform irregular growths, and the different trees be trained accordingly, fuffering the whole to branch away at full length, not fhortening any after the above general head ing down, when a year old, except it fhould eem occafionally neceffary, either to reduce any casual irregularity, or to procure a more full supply of lower branches; after which no further general fhortening fhould be practised to thefe fort of trees; for, after having obtained a proper set of regular branches near the head of the flem, they readily furnish more in their turn to inereafe the head on the upper part.

In regard to planting out the trees, they are moftly of proper growth for this purpofe when from one or two to four or five years old, from the graft or bud; but if larger trees are required, thofe of fix or eight years old may be safely transplanted; younger trees, however, always fucceed well, even when only two or three years old.

In felecting pear-trees for planting, Mr. Forfyth advifes the choofing of the oldft trees that can be found inftead of the young ones, and fuch as have strong flem; to have them carefully taken up, with as much of the roots as poifible, and carefully planted, after cutting in the roots a little, spreading them as horizontally as can be done. Then to fill up all round the roots with light dry mould, forcing it in, about thofe which lie hollow, with a sharp-pointed ftep; filling the whole up to the top without treafing the mould, till the hole be filled with as much water as it will contain, leaving it a day or two until the ground has abforbed the water; then to throw on fome fresh dry mould and tread it as hard as poifible, filling the hole up again with mould to within an inch of the top, and giving it a fecdow or mould, leaving the mould about three inches higher than the border, to fettle of itself, and to receive the rain that falls, for at lead a month. When the mould has become quite dry, it may be trodden a fecdow time; then make a large facho all round the tree, and giving it another watering, mulching the top over with fome rotten leaves or dung, fhould be done. When the tree is once a week in dry weather, and sprinkling the tops frequently with a pot, or hand engine, to keep the wood from thrivellng till they have taken fresh root; and where the trees are planted against a wall, the flem fhould be fted ftoping towards it; the lower parts of them being fix inches from the bottom of the wall, to give them room to grow, as when planted close to the wall at bottom, the flem, in growing, will be confined on the back, grow flat, and be very unfightly. If any roots are in the way, to hinder it from being planted near enough to the wall, they must be cut off; at the same time taking care that the tree does not lean to either side, but that, when viewed in front, it appear perfectly upright. Sometimes standards and half-standards are feen planted a foot or two from the wall, which gives them a very difagreeable appearance; fix inches is, he thinks, quite ftifficient. Much care fhould be taken not to wound the flem or root of the trees in planting.

When young trees have two flem, he advifes always to cut off one of them, leaving the ftuttle and fharpedge, planting that fide outwards which has moft buds on it.

It is added, that when the buds begin to break well, the trees fhould be headed down to three or four eyes, to fill the wall with fine wood, but never afterward, except in the leading fhoot to fill the wall, leaving the fide fhoots to be pruned, as hereafter directed. He has had fome trees that had forty pears on them the second year; while fome of the fame kind bore only eleven pears the fourteenth year after planting, with the common method of pruning. When fuch old trees as recommended above cannot be pro cured, the ftuttle and cleanf of the one-year's old grafting fhould be provided. Where any of these trees become fbunted after a number of years, they fhould be headed down as hereafter directed, which will bring them into fresh vigour and fruitfulnes. The properfeafon for planting them out is any time in open weather from the end of October till March, but the autumn or early winter are the moft advantageous periods. They fucceed well in any common garden soil, or good fertile orchard-ground, or field, that is not very wet, or of a fliff or Rubbonary quality, but moderately light and friable to the depth of one fpace at left, and if more the better. The ground fhould be prepared by proper trenching one or two fpades deep, as the depth of good foil will admit, wholly if for a full plantation, or only along the place for each row of trees, in the place for each tree; or only a hole for each tree at proper distances. The proper distance for planting the dwarf fotts for walls or efpaliers, is for three free flocks at not lefs than twenty feet, but if twenty-five, or more, the better, efpccially if the walls be rather low, &c. that there may be full fcope to extend their branches considerably in a horizontal direftion, as they will effeetually fill that space, or even much more if it be allowed them; but they are often planted much nearer to gether. It is however of importance to give thefe trees fufficient room, and the higher the walls the better, as is evident by thefe trees growing against the ends of high buildings, as they extend themselves very considerably every way. Some pears cherry-trees or other moderate flooting fruit-trees in the intervals for a few years, till the pears advance in growth and approach one another, when they fhould be removed. They are to be planted in the ufall way, with their heads entire. See PLANTING.

However, for trees that are dwarfs by grafting or bud ding upon quince flocks, from fifteen to eighteen feet may be a proper distance for planting, either for walls or efpaliers. In refpeft to the distance at which pear-trees fhould be planted against walls, it is obferved by Mr. Forfyth that when they are grafted on free flocks, such as colmars, pear d'auche, crafanes, pefchafleries, virginoleufs, and winter and flummer bonchfriens, it fhould at lead be twelve yards diifant.
PYRUS.

distant from each other, supposing the walls to be from twelve to sixteen feet high; but when they are only ten feet, fifteen yards will be little enough for the purpose.

And where they are planted on south walls, vines, peaches, nectarines, or apricots, may be planted between them, till the trees extend so far as nearly to meet each other; then they may be removed to any other situation in the garden where they are wanted. And where the pears are planted on west walls, the same fort of trees may be planted between them as on south walls; the fruit on a west aspect will come into use to succed that on the south. On an east wall different forts of plums and cherries may be planted between the pear-trees till they almost meet, then transplanted as standards or wall trees.

It is advised that the borders for pear-trees in a large garden should not be less than from ten to twenty feet wide, with a foot-path about three feet from the wall, covered over at top with coal ashes or road-fand, to make a dry walk for getting at the trees to cut and nail them, to gather the fruit, &c. And that the depth of the mould for them should never be less than three feet, laying the belt mould at top, to encourage the roots to come as near the surface as possible. If the bottom be clay, it will be very necessary, once in every five or six years, to open the ground round the roots of the trees, and cut off all the large ones that are inclining to run into the clay; as, by this practice, the trees will throw out fresh roots that will run near the surface, provided the mould is good near the top of the borders. And it is suggested that a crop of early peas, lettuces, spinach, or any other small crops, may be grown on the borders, during the winter and spring; but no late crops by any means. If the ground can be spared, he would advise to have no summer crops, but keep the borders hoed, in particular after rain; otherwise the ground, if a strong loamy or clayey soil, will be apt to crack in dry weather; but by frequent stirring between wet and dry this will in a great measure be prevented, and the sun's rays admitted into the mould, which will greatly heighten the flavour of the fruit. When you can conveniently spare the borders in winter, they should be ridged up to sweeten the mould, which may be very well done if you sow early peas on the sides of the ridges; which is by far the best way to preserve the peas from the frost, and to prevent them from rotting, which will sometimes happen, if the land be strong, before they begin to vegetate; or, you may sow an early crop of carrots or spinach on these borders.

With reference to the general management in the training and pruning of these trees, if the young wall and espalier trees thus planted are only one year old from the graft or bud, having their first shoots of a year old entire, these should in the spring be headed down to five or six inches, to force out lower horizontal branches; but if they have been previously headed, as advised above, and have thrown out laterals to form a regular set of horizontal branches, continuing of fix or more near the bottom, they should not now be shortened, but trained to the wall or espalier at full length horizontally, preserving an equal number on each side five or six inches alander; they will readily emit a further supply of horizontal shoots to cover the wall, &c. regularly upward, and at the same time not being shortened, they gradually form themselves for bearing, as every shortening of the branches of these trees retards their bearing a year at least; if, however, there is a want of branches, some of the middlemost may be pruned short, and trained to the wall or espalier. According as the trees shoot in summer, a further supply of all the regular shoots in every part where they occur, should be trained in at full length, unless it

shall seem necessary to prune some strong shoots to obtain a greater supply of horizontal branches the same year, in order to furnish the head as soon as possible; at this time, however, displace all the fore-right and other irregular growths of the year, continuing the supply of regular shoots close to the wall, as they advance in length during their summer's growth. And in the winter pruning, the supply of shoots attained in summer should be well examined, felling all those that are well placed and properly situated for training in, to increase the number of horizontal branches at each side, which should be left wholly entire, and at the same time retaining any favourable and ill-placed shoots omitted in summer; then the whole supply of regular horizontal branches in every part should be trained in straight and close to the wall or espalier, equally on both sides of the tree, every branch at the full length, at four, five, or fix inches apart. See Wall, Espalier-Trees, and Pruning.

But there is another method sometimes practised in training these trees for walls and espaliers, which is, that after their first heading down, and having thrown out several laterals, to fledge three of the strongest and most regularly placed, one on each side and one in the middle, nailing the two side ones horizontally at full length, and the middle one upright: the tree having produced a further supply of shoots in the following year, add two or four of them as side branches, arranging them on each side of the item as the two former, training the middle shoot still in an upright direction; observing that where it does not furnish horizontals low enough, it may be shortened so as to make it throw out shoots at any requisite height, continuing the middle one always upward for a item, and the side ones for bearers. In either of these methods of training the trees, continue yearly increasing the number of horizontal shoots, till the full space of walling or espalier is regularly covered with bearers at equal distances, constantly continuing them all at full length, as far as the scope of walling, &c. will permit; as they naturally form fruit-spurs every eye, almost their whole length, and the same branches continue in a fruitful state a great length of time. When the trees have once filled the wall or espalier with branches, they need but very little further supply for many years, and that only occasionally, according as any worn-out or decayed branch occurs, and wants renewing with young wood. See Pruning.

And in the after-prunings in the summer, which should be begun in May, or early in June, rub off all the superfluous and unnecessary shoots of the year, and all fore-right and other ill-placed shoots, retrenching them quite close, being careful to leave the terminating shoot of every horizontal or bearer entire; and referring here and there a well-placed shoot, towards the lower parts in particular, and where there are any apparent vacancies, to train up between the mother branches, till winter pruning, when, if not wanted, they must be retrenched.

But in the winter pruning, which may be performed at any time from the fall of the leaf until March, the branches should be generally examined, to see if they are any where too much crowded, or trained irregularly; and where any such occur, they should be regulated as they may require; and where there are any vacancies, some contiguous shoots, referred in the summer dressing, should be laid in, and all the other shoots not wanted must be cut clean out close to the branches, being careful still to prefer the terminating shoot of every branch entire, in all parts, as far as the allotted space admits, likewise all the fruit-spurs in every part, fastening in all the branches regularly at full length. In pruning old trees at this season, where decayed and worn-out branches occur, they should be cut out, and young wood trained in its
PYRUS.

Its stead: likewise, where any branch, through age or any other defect, is become barren, it should be retrenched, and some eligible lower young branch, or shoot, be laid in its place.

Where any of the choicer sorts of these trees are become worn-out and barren, they should be renewed with young bearers, by heading the branches wholly down near the bottom in winter or spring, when they break out in the old wood, and in the following summer furnish a large supply of strong young shoots, which should be trained according to the rules already laid down, when they will soon form a fort of new tree, and bear good fruit. After each winter pruning, the trees which are aged, it walls and espaliers require a general malling, &c. which should always be done with great regularity. See Wall-Trees, and Espalier-Trees.

The mode of training dwarf standard-trees of this fort is shown in speaking of trees of that kind. See Dwarf-Trees.

In respect to the culture of the borders where this fort of wall or espalier-trees are growing, it is commonly digging them once more every year, adding manure occasionally in common with the other parts of the garden; but if some good rotten dung be applied every other year, and the ground well dug or trenched every winter, it greatly promotes the size and perfection of the fruit. In regard to standard-trees of this kind, any of the forts bear plentifully in any open situation, though the fruit may not always be so large and fine as those of wall and espalier-trees; summer and autumn pears, however, ripen in great perfection on standards, as also most of the common winter pears. In planting them, trees of from two or three to four or five years old, having tolerable heads, are of a proper age and size for the purpose, and are preferable to older trees for any general plantation. They should be planted with all their heads entire, except retrenching any very irregular-placed branch, in the usual manner of tree-planting. See Planting.

In their future growth they should be suffered to branch naturally, so as to form large branchy heads, suffering them all to remain entire. The general culture of this fort of trees, in respect to pruning, is very trifling, and only required occasionally, probably only once in several years; such as the retrenching any irregular growing branches, and thinning such branches as are very much crowded, cutting out all the decayed wood, and eradicking suckers from the roots and stems. See Pruning.

When standard-trees are situated in a garden, in which the ground is necessarily dug over and trenched annually for the reception of the under crops, and occasionally enriched with dung, they generally produce finer fruit than in orchards, or other places where the ground is not in similar culture.

Mr. Forfith observes, that the method of pruning pear-trees is very different from that practiced for apple-trees in general, in which the constant practice has been to leave great spurs as big as a man's arm, standing out from the walls, from one foot to eighteen inches and upwards. The constant pruning inevitably brings on the canker; and by the spurs standing out so far from the wall, the blossom and fruit are liable to be much injured by the fruit and blighting winds, and thus the sap will not have a free circulation all over the tree. The spur, if always finds its way first to the extremities of the shoots; and the spurs will only receive it in a small proportion, as it returns from the ends of the branches; and the fruit standing at so great a distance from the wall is too much exposed to the weather, and, of course, is liable to be hard, spotted, and Kernelly.

The following method he has practiced where the trees were all over canked, and the fruit small, and not fit to be sent to the table. He cut the tops off as near as possible to where they were grafted, always observing to cut as close to a joint or bud as possible. The buds are hardly perceptible, but it can always be known where the joints, or forks, are, by the branches breaking out of the sides. He adds that finding the pear-trees in Kennington gardens in a very cankered and unfruitful state in the years 1784 and 1785, he cut out the old mould from the borders against the walls, and put in fresh loam in its stead; at the same time he pruned and nailed the trees in the common way, and left them in that state upwards of eighteen months, to see what effect the fresh mould would have on them; but to his great surprize he found that it had no effect. After this trial he began to consider what should be done in order to recover their old trees. In this attempt he began with cutting down four old and decayed pear-trees of different kinds, near to the place where they had been grafted: this operation was performed on the 15th of May, 1786. Finding that they put forth fine shoots, he headed down four more on the 28th of June in the same year (for by this time the former had shoots of a foot long), which did equally well, and bore some fruit in the following year. One of the first four he headed down was a St. Germain, which produced nineteen fine large well-flavoured pears next year, and in the third bore more fruit than it did in its former state when it was four times the size. He left seven trees upon an east wall, treated according to the common method of pruning, which bore the following number of pears upon each tree. Epine d'huyer produced eighty-six pears, and the tree spread fifteen yards; a crafane produced one hundred pears, and the tree spread fourteen yards; another crafane produced eighteen pears, and the tree spread ten yards; a virgouleuse produced one hundred and fifty pears, and the tree spread nine yards; a colmar produced one hundred and fifty pears, and the tree spread nine yards; another colmar produced seventy-nine pears, and the tree spread ten yards; a pêchererie produced sixty pears.

But seven trees headed down and pruned according to his own method, leaving the fore-right shoots in summer, bore as follows, in the fourth year after heading: a Louisbonne bore four hundred and sixty-three pears, and the tree spread nine yards; another Louisbonne bore three hundred and ninety-one pears, and spread eight yards; a colmar bore two hundred and thirteen pears, and spread six yards; a brown buerc bore five hundred and three pears; another brown buerc bore five hundred and fifty pears; a crafane bore five hundred and twenty pears; a virgouleuse bore five hundred and eighty pears. And he adds, that the branches of the four last trees spread nearly in the same proportion as the first three. He also states that a young buerc, the second year after heading, bore two hundred and thirty pears; and a St. Germain four hundred. All the above trees spread in the same aspect and the same wall, and the fruit was numbered in the same year. A great many pears which dropped from the trees are not reckoned. The trees that were pruned according to the old practice covered at least one third more wall than the other.

From this statement it appears that the trees headed down bore upwards of five times the quantity of fruit that the others did; and that it keeps increasing in proportion to the progress of the trees. This is an important statement in the culture and management of old trees of this fort; and the following fact with respect to standards is deserving of great attention: On the 20th of June he headed several standards that were almost destroyed by the canker; some of them were fo loaded with fruit the following year, that he was
was obliged to prop the branches, to prevent their being broken down by the weight of it. In the fourth year after these standards were headed down, one of them bore two thousand eight hundred and forty pears. There were three standards on the same border with the above, two of which were St. Germain; the old tree was of the same kind. One of these trees, twenty years old, had five hundred pears on it, which was a great crop for its size; so that there were on the old tree, which had been headed down not quite four years, two thousand three hundred and forty pears more than on the tree of twenty years' growth. When the men numbered the pears, there was near a barrelful of wind-falls at the bottom of the old tree, which were not included. These and other statements are given in his useful treatise on the "Culture of Fruit-Trees."

The following is the method he pursues in training trees that are cut near to the place where they are grafted. In the month of March, every year, he shortens the leading shoot to a foot or eighteen inches, according to its strength: this shoot will, if the tree be strong, grow from five to seven feet long, in one season; and, if left to nature, would run up without throwing out side-shoots. The reason for thus shortening the leading shoot is to make it throw out side-shoots, and if it be done close to a bud, it will frequently cover the cut in one season, leaving only a cicaatrix. When the shoots are very strong, he cuts the leading ones twice in one season; by this method he gets two sets of side-shoots in one year, which enable him the sooner to cover the wall. The first cutting is performed any time during the spring, and the second about the middle of June. When you prune the trees, and cut the fore-right shoots, which should be done in February or March, always cut close to an eye or bud, observing where you see the greatest number of leaves at the lower bud, and cut at them; and for at the footstalk of every one of these will be produced a flower-bud. The fame will hold good in cutting the superfluous shoots on standard pears. He adds, that you will have in some sorts of pears, in a favourable season, from five to nine pears in a chidler. This cutting should not be later than March, or the beginning of April, on account of the leading shoot beginning to grow: the next topping, when the leading shoot grows quick enough to admit of it, should be about the middle of June; and the length of the shoots should be according to their strength, having from three eyes or buds to fix on a side. It is added, that the cambium part beginning to affect the new bark, he cut off all the canker at the bottom, and plastered the place with some cow-dung, mixed with wood-ashes and powder of burnt bones, put into as much urine and foapuds as would make it of the consistence of thick paint; this he laid on with a painter's brush. After it had been applied about three hours, he patted it gently down, with his hand, close to the tree. By so doing, he gets rid of all the air-bubbles that may be under the composition, and makes it adhere to the tree, preventing it from being washed off by heavy rains. And in the beginning of August he shortens the fore-right shoots to about four inches long; by this time the shoot will have made its full growth for the season, and will produce fine strong eyes for the following year. Such shoots as grow near the limb of the tree, if any are wanted to fill up the wall, may be tuck-in as directed for peaches. This will prevent them from looking unprofitably, and save them from the fury of the autumnal and winter winds. He further advises, that whenever the trunk is hollow, it be followed under ground till you have cut out all the decayed parts and rotten roots, otherwise you will lose the tree. By proceeding according to the foregoing directions, the roots will be renewed, while the tree is forming a fine handsome head. In the mean time the borders should be trenched, taking up all the roots, and adding some fresh mould to them, if you can conveniently get it; if you cannot, remove all the mould that is about the roots of the trees, and put in some taken from the border, at a distance from the wall; always remembering to lay the top furthest next to the roots of the trees; also, to mix some vegetable mould, from the melons and cucumber beds, with rotten leaves, as a manure for the borders. He has headed down many trees that had not this preparation; and yet they threw very well, but did not yield such fine roots and shoots as those that were so prepared. He concludes by observing, that if the above directions be followed, more pears will be procured in three or four years than can be done in twenty-five years by planting young trees, and pruning and managing them in the common way. It is added, that if it should be found, that before the pears arrive at half their natural size, they get flunted, after cold blighting winds, and frothy nights, he would recommend a new operation to be performed when the weather begins to grow mild, which is to take a sharp penknife, and with the point of it make an incision through the hind of the pear from the footstalk to the eye, in the same way as in tarifying a bark-bound tree, taking care to penetrate as little into the flesh of the pear as possible. At the same time heat up some fresh cow-dung with wood-ashes, and with your fore-finger rub in a little of this compound where you made the tarring; as the wound heals, the composition will be discharged from the fruit; this will prevent the pears from cracking and bursting, which renders them good for nothing. The forts that are most liable to this disorder are, he observes, the colinar, virgoulence, and crafame. He only, however, recommends this operation for wall pears, as it may be thought by some a troublesome operation, and it will certainly take up some time.

Signs of Ripeens in the Fruit.—The maturity of the pear is generally known by its changing from a green to a yellow, or reddish colour, &c. and by the frequent falling from the tree; and when, with a gentle twist or turn upwards, it easily quits its hold: but these signs of ripeens are more particularly observable in summer and autumn pears, as winter pears, not being maturely ripe when gathered, often require a good pull before they quit the branches.

The summer pears ripen in succession in different sorts, from about the beginning or middle of July till the middle of September; many of the earliest ripening all at once, as it were, and continuing good but a few days, either on the tree or when gathered, nor will any of the sorts keep good long; and none of these sorts should hang on the tree till soft ripe, as in that case most of them would be mealy and intrepid. These sorts should be gathered as soon as they are arrived to full growth, and just begin to colour and discover maturity, but before they become soft and mellow. For family use, they may be gathered from the tree according as they attain perfection; but the general crops of each sort should be always taken down before they ripen fully, and be laid in any dry room; none of the kinds will keep long, some only a few days, and scarcely any of them above a fortnight, though from different varieties ripening at different times, the succession is continued for eight or ten weeks.

The autumn pears ripen in different varieties, from about the middle of September till the end of October; some of the forwardest become eatable on the tree, others requiring to lie some time after being gathered before they acquire perfection. The different sorts of these pears should be gathered according as they arrive to maturity: those defuiged
to keep some time, may be gathered in dry weather, just when they have attained full growth, as shown by their frequent dropping, and by their readily quitting the trees on being handled, and laid in a dry close room, or in baskets, each fort separately.

The winter kinds attain their full growth on the trees about the end of October or beginning of November; but the eatable kinds do not acquire maturity for that purpose on the tree, or for some considerable time after they are gathered, some probably in a month, others two or three, and some more, and some forts not till the spring following. But the baking kinds may be used any time from October or November during their continuance. All winter pears should be indulged with as full growth on the tree as the weather will permit, even until the end of October, or first week in November. In the latter kinds, if the season continues mild: be cautious, however, to get them gathered before attacked by much frost. And in gathering all the forts for keeping, dry weather should be chused, and when the fruit is also quite dry, being careful not to bruise them.

See Fruit.

Method of Forcing Pears.—These forts of trees are sometimes forced by artificial heat, in some of the prime early kinds, to obtain a portion of fruit as early in the season as possible. This is effected by means of hot-walls and forcing-frames; having previously some trees of the choicest early summer pears, such as the jargonemel, or any other early fort, trained as wall-trees against a south wall, till advanced to some tolerable state of bearing; being then enclosed with glass frames, in the manner of forcing-frames or hot-walls, and having internally either flues for fire, or heat, erected forward and extending long-ways, or otherwise a pit arranged in that direction, in the interval or space between the trees and the glass-work, for a bark or dung hot-bed; and by one or other of these methods a proper degree of artificial heat is produced internally to force an early growth in the trees, and forward them to early flowering and fruiting, managing them in the common way, as other trees in forcing-frames, so as to have some ripe fruit early in June, or some time in that month.

Method of Culture in the Apple Kind.—The whole of the varieties of the apple were first accidentally obtained by raising them from the kernels of the fruit; but as these cannot be depended upon to continue the same fort of fruit, grafting is the mode made use of to increase and continue the different varieties of them, which is performed upon crab, or any kind of apple stock, raised from the kernels, for dwarfs as well as standards; and sometimes upon codlin and paraflle apple stocks raised from cuttings and layers, when designed to have epaliers and other dwarf trees, or for small standards, as low as possible, to be confined within a moderate space: some forts may also be raised by layers and cuttings, as the common codlin.

Stocks.—The method of raising the different forts of stocks for the purpose is, in the crab and apple stocks, from the kernels of the fruit; but in the codlin and paraflle stocks by cuttings, to continue them with certainty of the same kinds and moderate growth. The crab and apple stocks may be raised from the kernels of any of the forts, procuring them in autumn or winter, either from the fruit, or from such as have been proflled for ver- juice and cider, clearing them from the gross part of the pulp; then foaming them in beds of light earth, moderately thick, over the bed, or in drills, covering them about an inch deep. They come up in the spring; when, if the season prove dry, they should be watered occasionally, to forward and strengthen the growth of the plants; and in the autumn, winter, or spring following, the largest may be planted out in nursery-rows, shortening their tap- roots a little, and placing them in lines two feet and a half apart, or even for full and half standards, if intended to form the item from the graft, which is an eligible method for these trees; but if the stock is to form the item, they require three or four years' growth, to rife to a proper height, seven feet for full, and four or five for half standards. The modes of grafting all the forts are the same as for other fruit-trees, and should be performed in March, either by whip or peel-grafting, according to the size of the stock. See Graft.

Having provided proper grafts of the different sorts of apples intended to be raised, the stocks designed for dwarfs of all sorts must be grafted within six inches of the ground; and the standards may also be grafted low, one shoot from the graft being trained up for a item, or on tall stocks, at five or six feet in height, but for low and half standards, at two or three, to four or five feet, and lower for dwarf standards. The grafts of all the sorts shoot the same year; and, by the autumn following, the trees having formed little heads, confining of two, three, or four shoots, may then be planted out finally where they are to remain, or be retained a year or two, or longer, in the nursery, as may be requisite, training them for the purposes intended, as dwarfs, epaliers, &c. &c., and uprights for standards, heading the dwarfs down in March following, within six inches of the graft, to force out more lateral shoots below to form a fuller head, proceeding immediately to turn them near the bottom, fo as to fill the epalier, &c. equally with branches, quite from within six to eight inches of the ground, regularly upward. In the standards, those grafted low must be trained with one shoot upright, at full length, for a item, five or six feet high at least, for full standards before it is topped; though if grafted on tall stocks of height sufficient for a item, the shoots from the graft may either be headed to five or six eyes; or, if to form a more spreading head, remain entire, and aspire more in height, and assume a more upright growth; in all the modes of training, care should be taken to keep the items clear from all lateral shoots, displacing all such as soon as they appear, encouraging only a proper set of branches at top to form the head. When these trees have heads from one to two or three years old from the graft, they are of a proper age for planting out; though trees of four or five years old will also succeed very well, and even those of six or eight years' growth may also be safely planted if required. The nursery-grounds are mostly furnished with all the varieties of these trees for sale, either quite young from the graft, or trained of several years' growth.

Choice of Trees.—In choosing the different kinds of trees for planting, care should be taken to have a collection of the principal varieties, both in epaliers and standards, in proportion to the extent of the ground, as the trees of the best sorts are as easily raised and cultivated as the indifferent ones, allowing a smaller portion of the summer kinds, as such as ripen from August to about the middle of September, for immediate use of the trees, as they will not keep long; a larger supply of the autumn sorts, and most of all of the winter keeping apples: observing, in the summer kinds, that it is advisable to allot a principal supply of the common codlin in small standards, as being generally both a great bearer, and the fruit the most useful of the summer apples for culinary purposes, from its young green growth.
growth in June or July, till its full maturity in August and September, when it becomes also a good eating apple: and as the tree is a moderate grower, it admits of being planted in small standards closer or more abundant in a small extent of ground than most of the principal apple kinds.

In choosing apple-trees from the nursery, they should, Mr. Forsyth says, have strong, straight, and clean items. And he advises not to suffer the dwarf trees to run higher than twelve feet, as otherwise they become naked at bottom, the fruit is liable to be blown down, and the tops broken by high winds.

The proper season for planting all the sorts of apples is, in mild weather, from the end of October till March; but when planted in autumn, or early in winter, they establish themselves more firmly before the drought of the following summer. They succeed in any common soil and open situation, except in low very moist land, in which they are apt to canker, and soon go off; in a pliable mellow loam they generally anwer very well. The ground should be properly prepared, by good trenching, where the ranges of trees are to stand.

In the planting of espalier apple-trees they should be ranged at no less than eighteen or twenty feet distance; the latter especially for trees grafted on crab or apple stocks, which being free Shooters, the branches readily fill that space. For the trees grafted on codlin and paradise stocks, fifteen or eighteen feet may be sufficient; though the latter, in particular, is sometimes planted only twelve or fifteen feet asunder, as being a very moderate Shooter: it is, however, advisable to allow every foot full room, according to their growth, to have proper space to extend their branches always at full length. The trees should be planted with all their heads entire, only retrenching any very irregular growths, that do not range contently with the intended form, and pruning any broken roots. Then having opened a proper hole for each tree, plant them in the usual manner, being careful to place them with their branches ranging the way of the espalier. As soon as the earth of the holes and of the roots is properly settle, all the branches should be trained in horizontally to the right and left, an equal number on each side at full length, as above.

The general culture in espalier trees thus planted and trained, as the same branches or bearers continue fruitful many years, is to continue them as long as they remain of proper growths, constantly giving them a summer and winter pruning annually, as explained above. In wall-trees also, any of the principal choice varieties of eating apples may be trained, to forward and improve the growth, beauty, and flavour of the fruit; such as jennetings, Margaret apple, golden pippins, golden rennets, pearmans, &c. or any other approved eating kinds, a tree or two of a sort, against a south, south-west, or east wall.

Standard apples, when planted in the garden, should be arranged thinly, to admit of under crops growing freely, without being shaded by their spreading branches. Full standards should be chiefly planted for the general crops, and half and dwarf standards for variety. The standards, when trained as above, should be planted out with all their heads entire, when in the kitchen garden, at thirty feet distance in the rows; and for an orchard, thirty feet distance every way. In planting, for each tree a wide hole should be opened, trimming any long fragglings and broken roots, leaving all the others entire, and planting them with the usual care. As soon as planted out, every tree should be well flaked to support them firmly upright, and prevent their being disturbed in rooting by winds. See Orchard and Planting.

Smaller growing standards, such as codlins, or other low standards grafted upon codlin stocks, and dwarfs upon these or paradise stocks, may, if required, be planted only at fifteen or twenty feet distance in the rows, and not less than twenty-five feet between the lines of trees; though, if there be room to allow a greater distance both ways, it will be advantageous, especially in planting in kitchen gardens, in which it would be proper to allow double the distance between the rows of trees, of the larger growths of these kinds. The standards thus planted with their heads entire, should be suffered to advance with their branches at full length, and in general take their natural growth, when they form numerous natural spurs in every part for bearing.

In respect to pruning these standards, little is required, only the occasional retrenching any irregular cross-placed bough, or the reducing to order any very long rambler; or when the head is become greatly crowded and confounded to thin out some of the most irregular growths, likewise all strong shoots growing upright in the middle of the head, and all dead wood, and suckers from the stem and root.

As to half and dwarf standards of these trees, they may be differed in different parts of the garden to cause variety, managing them as the full standards. The former on dwarf paradise stocks, being very moderate Shooters, may be planted in a little compass; and are sometimes planted in pots for curiosity, to place on a table, amidst a delft, with the fruit growing on them. See Dwarf-Trees.

It is observed by Mr. Forsyth, that in heading down old decayed apple-trees, for the sake of symmetry, it will be necessary to cut at the forked branch as near as can be to the upper side of the fork, cutting them in a sloping manner to carry off the wet, at the same time rounding the edges. To begin at the lower branches, cutting just above the lower fork; and proceeding upwards, cutting the rest of the branches from one to fix joints, or forks, according to their strength, till you have finished cutting in the whole head. If any of these branches should have the canker, all the infected part must be cut out. When the tree is all prepared, the composition should be immediately applied, beginning at the top of the tree, and finishing with the powder of wood-shakes and burnt bones as you descend, which will save it from being rubbered off during the operation; and the composition will prevent the fun and air from injuring the naked inner bark. A tree thus prepared, will in the course of three or four years, produce more and finer fruit than a maiden tree that has been planted upwards of twenty years.

These directions, if properly attended to, will be sufficient, it is supposed, to enable any one to bring old decayed trees into a healthy bearing state.

It is believed, that in large orchards and gardens, it may be necessary, at first, to head down only every other tree; cutting some of the branches of the rest, which are in a decayed and cankerly state, and which bear no fruit. This will be preparing them to throw out new wood, and furnish the tree much sooner with bearing branches. He recommends the performing of the operation as early as possible; as by so doing the wood will be the stronger, as in May, or the two following months.

And it is added, that when the trees are become hollow, the same method should be followed as directed for plums; but by no means to cut them down unless the tops are quite decayed; observing to cut the loose rotten wood clean out of the hollow and other decayed parts, applying the composition; at the same time to open the ground, and cut out
all the rotten parts that may be found in the lower part of
the item, together with all the decayed roots, which, if
this be not done, will infallibly injure the fresh wood
and bark, and prevent a cure from being effected. He would
recommend heading down all apple-trees that are much
canker'd and have ill-shaped heads; as by so doing much
labour will be saved, and the trees will amply pay the
proprietor. He advises never to shorten the young branches,
except they are very thin, when it will be necessary to do so
to fill the trees with young wood: nor prune any of the
young wood, nor prune any of the young shoots the second
year (he means the year after they are cut), as many of the
eyes, almost to the end of the shoot, will, if he be strong,
become fruit-buds next year; and so on every year. It is
contended, that in the month of May in the first year after
the trees have been so cut, it will be necessary to go over
them, and rub off with your finger and thumb all the su-
perfluous young shoots; leaving from three to six eyes on
each shoot, according to the size and strength of the branch
cut. Theose shoots will bear from three to four years; by
which time they will be pretty much exhausted by the great
quantity of fruit produced from them: they should then be
cut down to two eyes to produce new wood. He always
leaves three different years' branches on the tree, when the
first shoot is cut off. This is fully shown in a plate in his
useful work; and the next shoot will be full of fruit-buds,
if it has not been shortened: when it begins to grow weak,
should be cut off; and the next cutting must be made
when the former branch is tired of bearing; by proceeding
thus all over the tree with care and attention, the advantages
of this method of pruning, above the common mode, will soon
be perceived; as by it you will be able to keep the trees in
a constant state of bearing, which, if left to nature, would
only produce a crop of fruit once in two or three years.
When the shoot that is done bearing is cut off, the com-
position should constantly be applied, rubbing off the shoots
where they are too numerous.

It is sup ped, that the best time to prune apple-trees is
in the month of April, or in May, after the operation has
been performed on the peaches, nectarines, and cherries:
and that soon after this pruning, about the middle of May,
it will be proper to look over the trees, and to pick off any
caterpillars that may be on them. It will then be seen what
shoots are infected with the canker, and which might have
eclaped your notice at the time of pruning; and wherever
you observe the bough appearance of infection, which may be
known by the wood appearing of a brownish colour, the shoot
must be cut down till you come to the sound white
wood. The small shoots that cross each other should be cut
off, leaving the strong one to fill up the tree, and make a fine
handsome head. The suckers that spring from the root
should be carefully grubbed up, and the side-shoots from the
them cut off; for, if left to grow, they greatly weaken the
tree. The knots, where old branches have been cut off, should
also be pared away, leaving the surface of the tree as smooth
as possible: after which, the composition should be applied:
the young bark will soon begin to grow, and by degrees
cover the old wounds with a fresh smooth surface, and thus
prevent the canker from gaining ground on the tree. He
has seen some old wounds of considerable size, healed over
in one year; and he adds, in confirmation of the utility of
this practice, that the tree which he pruned and dressed, as
above directed, in the court of the sumner, 1795, are all
perfectly cured, the wounds being filled up with sound
wood, and covered over with new bark; they all continue in
a healthy state, and bear fine handsome fruit. And he
has advised several nurserymen to follow the practice, head-
ning down their apple-trees after the season of drawing ter
sale is over. Mr. Gray and Weer have headed a great
many of such trees as were formerly thrown into the faggot-
pile, and have been amply recommended for their trouble.
Trees thus headed down, provided the items be strong, will,
he thinks, in the first and second year, produce as much
fruit as will refund the purchase-money; besides, a great
deal of time will be saved, which would be lost by planting
younger trees: as, where you can procure trees of the
above description that have been headed down three or more
years, they will be all covered with fruit buds; and, if care-
fully taken up and planted in the autumn, if the season
proves favourable, they will have a tolerable crop of fruit
the first year. Such trees must not be headed down like
maiden trees, but only thinned off where the branches run
across and rub against one another, which should never be
suffered in these cases. He says, he would never recom-
mend training apple-trees as espaliers; as by doing so the
air is kept from the quarters of the garden; and by con-
stant pruning and cutting off all the side-shoots which you
cannot tie to the espaliers, you prevent them from bearing,
and, moreover, bring on the canker. And when the dwarf
trees have handsome heads, more and much finer fruit
will be gotten from one of them than from six espaliers. At
the same time, a free air is admitted to the crops in the quarters,
and the constant expense of the flakes and labour, in laying
the trees to the espaliers is saved. Espaliers may, he
observes, be converted into dwarf standards by shortening
the branches at different lengths, so as that they may be able
to support themselves without the flakes; but not to shorten
them all regularly; and if cut with judgment, as near to a
leading shoot, or an eye, as possible, they will in the course
of two years form fine heads, and in the third year bear six
times the fruit as they did in their former state, and of a
finer flavour. The same method of pruning as already laid
down for standard apple-trees is also applicable to espaliers.

It is remarked, that the borders where you make your
croppings in gardens should be six or eight feet broad at least,
to let the trees spread on each side, at the distance of twelve
feet from tree to tree, and they should be well trenched, two
feet and a half deep at least. If there should be gravel, or
four clay, it must be taken out, and good mould put in its
place; leaving the ground as rough as possible for the frost
and rain to mellow it. When you level the ground it should
be done after rain; you may then sow some small crops in
the border; such as lettuce or purslane, or cabbage for trans-
planting; but let not any of the brassica tribe come to full
growth. Leaving cabbage and broccoli on borders, near
fruit-trees, draws the ground very much, fills the borders
with insects, and also prevents the sun and air from penetrat-
ing into the ground. And when the sun can have free ac-
cess to the border, it adds much to the flavour of the fruit.
If you can spare the ground on the crofs-borders in winter,
it will be of great service to the trees to ridge it up as loose
as you can, and let it lie in that state all winter, to mellow
and sweeten.

Where the soil is strong, he would recommend planting
of apple-trees that are grafted on paradise stocks; but if the
soil be light, free stocks will do much better: and when the
ground is strong clay or brick-earth, it should be mixed
with old lime-rubbish or coal-ashes, street-dung, or sand:
but what he uses for the borders against the walls, and
which he prefers to every other mixture, is a vegetable
mould produced from leaves of trees. Of this a good
soil should be given once in two or three years, which will be
sufficient, he thinks, for the borders where the wall-trees
stand, and much better than dung, which he by no means
approves.
In respect to grafting old apple-trees, he says, it frequently happens, that through some mistake or other, after waiting ten or twelve years for a tree to come into a bearing state, it is found that the fruit is neither fit for the table nor kitchen; in such cases they should always be grafted the following spring, observing to graft on the fine and healthiest shoots, and as near as possible to the old graft, and where the crofs-shoots break out; as by so doing you will have some fruit the second year; and in the third, if properly managed, you will have as much as on a maiden tree of fifteen years standing; the canker, if any, must be carefully pared off the branch, and the icon must be taken from a found healthy tree. Whenever an incision is made for budding or grafting, from that moment the canker begins. He would, therefore, recommend to those employed in budding or grafting, as soon as the incision is made, and the bud or graft inserted, to rub in with the finger, or a brush, some of the compoition before the hafs is tied on; then to cover the hafs all over with the compoition as thick as it can be laid on with a brush, working it well in. If this operation be performed in a proper manner, and in a moist season, it will answer every purpose without applying any grafting clay; as he has frequently done it, and found it succeed perfectly to his wishes. The matting which is wrapped round the bud should not be flanked too soon; and in that case you will find the incision opened, which very often occasions the death of the bud. If, says he, nurserymen and gardeners would give this method a fair trial, and use the same compoition as he uses for curing defects in trees, instead of loam and horse-dung (which binds so hard as to prevent the rain and moisture from penetrating to the graft to moisten the wood and bark), they would find that the grafts would succeed much better. The compoition, for this purpose, should be rather softer than grafting clay generally is; and instead of applying so large a mass as is generally done of clay, it need not, in moist cafes, be more than two or three inches in circumference, to effect the purpoze.

Apples come to full growth in different sorts successively, from July until the end of September; the summer kinds continue but a short time, but the autumn and winter apples keep from two or three to six or eight months, and longer in different varieties. The signs of perfection or full growth of the different sorts of apples, are by their assuming a lively colour, emitting a fragrant odour, frequently falling from the tree, and by quitting their hold easily on being handled.

Gathering.—In the gathering of all the sorts of apples for keeping, dry weather should always be chosen; and when the trees and fruit are also perfectly dry; observe likewise, in gathering apples for the table, and all kinds of apples designated for keeping any considerable time, that they be pulled one and one by hand. See Fruit.

The other species may be increased by grafting and budding them upon the common crab-stock: they should have sheltered situations, as they are rather tender while young. These trees afford ornament and variety in the clumps and shrubbery parts of pleasure-gounds.

Method of Culture in the Quince Kind.—These trees may be raised from the kernels of the fruit found in autumn; but there is no depending on having the same sort of good fruit from seedlings, nor will they soon become bearers. But the several varieties may be continued the same by cuttings and layers; also by suckers from such trees as grow upon their own roots, and likewise be increased by grafting and budding upon their own pear-stocks, raised from the kernels in the same manner as for apples.

The raising by cuttings, layers, and suckers, is performed in autumn, winter, or spring, choosing young wood for the cuttings and layers, which should be planted and laid in the common method, when they will be rooted by the following autumn, then planted out into nursery rows two feet asunder; plant the suckers also at the same distance, and then train the whole for the purpozes intended; if for standards, run them up with a stem to any desired height, from three to five or six feet, then encourage them to branch out at top, to form a head; and those designed as dwarfs must be headed near the ground, and trained accordingly for espalliers, or dwarf standards, as directed under those articles: the grafting or budding is effected on quince or pear-stocks, and trained as above. When they have formed tolerant heads, they should be planted out finally.

Mr. Forfyth advises that the layers or cuttings should be planted in a shady place, in rows at about a foot distant from each other, and about three inches from plant to plant in the rows; mulching them with roven leaves, or mixtures, which will keep the ground about them moist, and watering them frequently in hot weather. About Michaelmas those that are well rooted may be planted out, and those that are not should remain another year. They may also be propagated by budding or grafting; and these trees will bear sooner, and be more fruitful than those raised by any other method.

He observes, that the quince-tree may be pruned much in the same way as an apple-tree, taking care to cut out all the old diseased and dead wood, and the crofs branches in the middle of the tree, which are apt to injure each other by friction. In general you will find old trees much hurt by injudicious pruning; in that case they should be headed down, cutting out all the canker-y parts, and also all the diseased and dead wood where the tree is hollow, or where large branches have been cut or broken off, applying the compoition as for apple-trees: and as quince-trees are very apt to have rough bark, and to be bark-bound, in these cases it will be necessary to have off the rough bark with a drawknife, and to score it when bark-bound, brushing them over with the compoition. It is also advised to plant quince-trees at a proper distance from apples and pears, as bees and the wind may mix the farina, and occasion the apples or pears to degenerate.

Standard quinces, designated as fruit-trees, may be fattened in the garden or orchard, and some by the sides of any water, pond, watery-ditch, &c. as they delight in moisture, suffering the whole to take their own natural growth: and as espalliers, they may be arranged in allembaglance with other moderate growing trees, such as apples and pears on paradise and quince-stocks, cherries, &c. being trained as directed for apples and pears in espalliers. They may also be planted in shrubbery, either as full or low standards, and permitted to take their own way of growth. See Orchard.

PYSTERA, in Ancient Geography, an island situated on the coast of Aila Minor, off-against Smyrna. Playth.

PYTHAGORAS, in Biography. See Pythagoreans. Pollyart has been very liberal to this philosopher, in following upon him all such inventions as others had neglected to claim, particularly in music; for there is scarcely any part of it, as a science, with which he has not been involved by his generous followers in biography.

Mathematical ratios have been assigned to him, with the method of determining the gravity or centriols of sounds by the greater or less degree of velocity in the vibrations of strings; the
PYTHAGORAS.

the addition of an eighth to the lyre (Pliny, lib. ii. cap. 2); the harmony of the spheres (Plato); and the Greek musical notation (Boethius). His right, indeed, to some of these discoveries has been disputed by several authors, who have given them to others with as little reason, perhaps, as they had been before bestowed upon him.

But there is one discovery, relative to music, that has, at all times, been unanimously ascribed to him, which, however, appears to us extremely doubtful, not only whether it was made by him, but whether, in the manner it is related, it was ever made by any one.

We are told by Nicomachus, Gaudenzius, Jamblichus, Macrobius, and all their commentators, that Pythagoras, one day meditating on the want of some rule to guide the ear, analogous to what had been used to help the other senses, chanced to pass by a blacksmith's shop, and observing that the hammers, which were four in number, sounded very harmoniously, he had them weighed, and found them to be in the proportion of 6, 8, 9, and 12. Upon this he suspended four strings, of equal length and thickness, &c., fastened with weights, in the above-mentioned proportions, to each of them respectively, and found that they gave the same sounds that the hammers had done; viz., the fourth, fifth, and octave to the gravest tone, which interval last did not make part of the musical system before; for the Greeks had gone no farther than the heptachord, or seven strings, till that time." Principles and Power of Harmony, p. 8.

This is the substance of the account, as it has been lately abridged by Mr. Stillingfleet, who points out many incredible circumstances with respect to the story in general, and denies that the weights 6, 8, 9, 12, would give the intervals pretended; but seems not to have seen the difficulty in the fact, relative to different hammers producing different sounds upon the same anvil. The frontispiece to M. Marpurg's History of Music, represents the Samian fable in the act of weighing the hammers.

But though both hammers and anvil have been swallowed by ancients and moderns, and have passed through them from one to another, with an off-fish-like digression, upon examination and experiment it appears, that hammers of different size and weight will no more produce different tones upon the same anvil, than bows or clappers of different sizes will from the same string or bell.

Indeed, both the hammers and anvils of antiquity must have been of a construction very different from those of our degenerate days, if they produced any tones that were strictly musical. Of the millions of well-organized mortals, who have passed by blacksmiths' shops, since the time of Pythagoras, we believe not one was ever examined by a single note, much less by an harmonious sound, from those Valcanian instruments. A different kind of noise, indeed, will be produced by hammers of different weights and sizes; but it seems not to be in the power of the most subtle ear to discover the least imaginable difference with respect to gravity or acuteness. But though different noises may be produced from different bodies, in proportion to their size and solidity, and every room, chair, and table, in a house, has a particular tone, yet these noises can never be accounted like musical tones, which depend upon reiterated and regular vibrations of the agitated parts of a string, or other elastic body; and in wind instruments, upon the undulations of the air conveyed into a tube. Noise may, indeed, be forced from a musical string, or instrument, by violence; but noise proceeding from bodies inelastic, or immaterial, can never be fastened into sound. M. Roudaut (Dict. de Mus. art. Bruit) has ingeniously imagined that noise is of the same nature as sound, with this difference, that to produce sound, the one tone, with its consonant harmonics only, should be heard; such as the 8th, 12th, 15th, and 17th; whereas noise is produced by a jarring multitude of different tones, or even by one tone, when its vibrations are so violent as to render audible a considerable number of dissonant tones, of which the vibrations seldom or never coincide; such as the 7th, 9th, 11th, &c.

The long belief of this story proves that philosophers themselves have sometimes taken facts upon trust, without verifying them by experiment. And as the tone of the hammers was affected without proof, so was the effect of their different weights fastened to the strings; this Galileo discovered. The numbers 6, 8, 9, 12, applied to different lengths of strings, would, indeed, give the intervals mentioned. But it is proved, that to produce these intervals by the tension of different weights, the weights must be the squares of those numbers; that is, 36, 64, 81, 144. It is ascribing how the blunder had been echoed from author to author, without experiment, till the time of Galileo. And Bontempi, in trying the power of weights upon strings in the Pythagoric proportions of 6, 8, 9, 12, found, that instead of giving the 4th, 5th, and 8th of the gravest tone, they produced only the minor 5th, major 3rd, and tritone; so that the whole account falls to the ground. But though modern incredulity and experiment have robbed Pythagoras of the glory of discoveing musical ratios by accident, he has been allowed the superior merit of arriving at them by meditation and design. At least the invention of the harmonic canon, or monochord, has been ascribed to him both by ancient and modern writers. (See Monochord.) See Arifild. Quint. p. 116. Prim. and Power of Harm. hist. des Mathem. par. Montuc. Euler, Tentamen Novae Theor. Mus. and all the writers upon harmonics and temperament.

We shall enter no deeper into this subject here, than is absolutely necessary to explain the nature of the discovery attributed to Pythagoras, to which music is indebted for the honourable appellation of science.

Pythagoras supposed the air to be the vehicle of sound, and the agitation of that element occasioned by a familiar agitation in the parts of the sounding body, to be the cause of it. The vibrations of a string, or any other resonant body, being communicated to the air, affected the auditory nerves with the sensation of sound; and this sound, according to him, was acute or grave, in proportion as the vibrations were quick or slow. It was also known, by experiment, that of two strings equal in every thing but length, the shorter made the quickest vibrations, and gave the acuter sound; in other words, that the number of vibrations made in the same time by two strings of different lengths, were inversely as those lengths; that is, the greater the length, the smaller the number of vibrations in any given time. By these discoveries it was that sound, consisting in the vibrations that caused it, and the dimensions of the vibrating or resonant body, was reduced to quantity, and as such, became subject to calculation, and explicable by numbers. Thus, for instance, the two sounds that form an octave are expressed by the numbers 1 and 2; which represent either the number of vibrations in a given time, or the length of the strings; and mean nothing more mysterious than that the shorter found sounded twice, while the greater sounded once; or, that the string producing the lower sound is twice the length of that which gives the upper. If we consider the vibrations, the higher found is as 2, the lower as 1; the reverber, if we consider only the lengths. In the same manner, and in the same sense, the 3rd is expressed by the ratio of 2 to 3, and the 4th by that of 3 to 4.
PYTHAGORAS.

Such was the ancient philosophy of sounds, of which Pythagoras is recorded as the first teacher. But how much of this theory was founded on experiment and demonstration, and how much of it upon hypothesis; how much of it was known, and how much taken for granted, cannot certainly be determined. The story just now discussed is too much embarrassed with absurdities and impossibilities to guide us to any probable conjecture, as to the method by which Pythagoras 

acted actually arrived at his conclusions.

The discovery, as far as it relates to the length of strings, was easily made, because it depended upon an obvious experiment. It was, likewise, easily perceived, that a short string vibrated with more velocity than a long one; but between the certainty of this general fact, and the certainty that the vibrations were in a ratio exactly the inverse of the lengths, there is a considerable gulph. (See Smith'sHarmonics, sect. i. art. 7, and note f.) We have no account of the bridge upon which Pythagoras got safely over. Experiment, here, is out of the question; for the lowest vibrations that produce musical sound, are far too quick to be counted or distinguished. The inference, however, was natural, though it does not appear that the ancients were able to support it by strict and scientific proof.

Indeed it was so late as the beginning of the present century, (1714. See Phil. Trans. and Methodus incrementorum directa et inversa, by Dr. Brook Taylor,) before this ancient theory of sound was fully confirmed, and the laws of vibrations, and the whole doctrine of musical strings, establis hed upon the solid bases of mathematical demonstration.

The second musical improvement attributed to Pythagoras, was the addition of an eighth string to the lyre, which, before his time, had only six, and was thence called a heptachord. It is supposed by several ancient writers, that the scale of this instrument, which was that of Terpander, consisted of two conjoint tetrachords, E F G A B C D; and that Pythagoras, by adding an eighth found, at the top, and altering the tuning of the fifth, formed this scale: E F G A B C D E, or a similar scale, consisting of two disjunct tetrachords.

How this scale was generated by the triple progression, or series of perfect 8ths, the abbe Rouffer has lately very well discussed, in his "Memoire sur la Musique des Anciens." We shall endeavour to explain what is meant by the triple progression in music, which is the basis of this ingenious hypothesis; referring the reader to the Memoire itself for his proofs, as inferring them here would require too much time and space for a work of this nature.

Let any found be represent'd by unity, or the number 1; and as the 3d part of a string has been found to produce the 12th, or octave of the 5th above the whole string, a series of 5ths may be represented by a triple geometric progression of numbers, continually multiplied by 3, as 1 3 9 27 81 243 729; and these terms may be equally suppos'd to represent 12ths, or 5ths, either ascending or descending. For whether we divide by 3, or multiply by 3, the terms will be in the proportion of 12th, or octave, to the 5th, either way. The abbe Rouffer, imagining that the ancients fang their scale backwards, as we should call it, by descending, annexes to his numbers the founds following:

Term I II III IV V VI VII
1 3 9 27 81 243 729
B E A D G C F
out of which series of 5ths, by arranging the founds in diatomic order, may be formed the heptachord, or 7th, B C D E F G A; and to these, adding the duple of the highest found, in the proportion of 2 to 1, the abbe supposes that Pythagoras acquired the octave, or profalambomenos. This is throwing a mite into the charity-box of poor Pythagoras, without, however, telling us in what reign the obolus was coined; for we have met with no ancient author who believes the invention of profalambomenos upon this philosopher.

The abbe Rouffer imagines, however, that though Pythagoras went no farther than the eighth term in triple progression, yet the Egyptians, in very high antiquity, extended the series to twelve terms, which would give every possible mode and genus perfect. A curious circumstance is observed by the same author, p. 28, § 47, with respect to the musical system of the Chinefe, which well deserves mention here. In collecting," says he, "what has already been advanced concerning the original formation of the Chinese sytem, it appears to begin precisely where the Greek left off, that is, at the VIIIth term of the triple progression, which is purfued as far as the XIth term, by which series, arranged diatonically, the Chinese acquire their scale, e b D b, B b, A b, G b, E b, in depending; or, as Rameau expresses the fame intervals, in sharps, ascending, G 8, A 8, C 8, D 8, E 8, G 8."—It is observable that both these scales, which are wholly without femitones, are Scottifh, and correspond with the natural scale of the old fimple enharmonic, given p. 34. M. Jamard, a late French writer on music, pulling calculation still further than either the Egyptians or Chinese, has obtained, by purfuing the harmonic feries, 1 2 3 4 &c. &c. not only the enharmonic diatems, but even the minute intervals in the warbling of birds; it is wonderful he did not apply his ratios to human speech.

After musical ratios were discovered and reduced to numbers, they were made by Pythagoras and his followers, the type of order and just proportion in all things; hence virtue, friendship, good government, celestial motion, the human soul, and God himself, were harmony.

This discovery gave birth to various species of music, far more arange and incoercible than chromatic and enharmonic; such as divine music, mundane music, elementary music, and many other divisions and subdivisions, upon which Zarlini, Kircher, and almost all the old writers, never fail to expatiate with wonderful complacency. It is, perhaps, equally to the credit and advantage of music and philosophy, that they have long descended from these heights, and taken their proper and separate stations upon earth; that we no longer admit of musick that cannot be heard, or of philosophy that cannot be understood.

Arctides Quintilianus affur'es us, that music comprehends arithmetic, geometry, physics, and metaphysics, and teaches every thing, from proportioning the scale, to the nature and constitution of the soul of man and the soul of the universe. To confirm this, he quotes, as a divine saying, a most curious account of the end and benefits of music, from one master Panacmus, which informs us that the province of music is not only to arrange musical founds, and to regulate the voice, but to unite and harmonize every thing in nature. This writer, p. 102, in solving the quesion, whence it is that the soul is so easily affected by instrumental music, acquaints us, in the Pythagorean way, how the soul, frisking about, and playing
playing all kinds of tricks in the purer regions of space, approaches by degrees to our gross atmosphere; gets a taste for matter and solidity, and at length acquires a warm and comfortable body to cover her nakedness. Here the picks up nerves and arteries; there membranes; here spirit or breath, and all in extraneous manner; especially the arteries and nerves: for what should they be made of, but the circles and lines of the spheres, in which the soul gets entangled in her passagie, like a fly in a spider's web. Thus, continues he, the body becomes similar to itself in the texture to instruments of the wind and entangled kind. The nerves and the arteries are strings, and at the same time they are pipes filled with wind. "What wonder, then," says Arilides Quintilianus, "if the soul, being thus intimately connected with a body similar in constitution to those instruments, should sympathize with their motions."

Mater Thomas Mace, author of a most delectable book, called "Music's Monument," would have been an excellent Pythagorean; for he maintains that the mystery of the Trinity is periphrastically made plain by the connection of the three harpical concords, 1, 3, 5; that music and divinity are nearly allied; and that the contemplation of concord and discord, of the nature of the octave and unison, will strengthen a man's faith, "that he shall never after degenerate into that gross fullebodied fin of atheism." P. 268.

Pythagoras is laid, by the writers of his life, to have regarded music as something celestial and divine, and to have had such an opinion of its power over the human affections, that, according to the Egyptian sylem, he ordered his disciples to be waked every morning, and halted to sleep every night, by sweet sounds. He likewill considered it as greatly conducive to health, and made use of it in disorders of the body, as well as in those of the mind. His biographers and secretaries even pretend to tell us what kind of music he applied upon these occasions. Grace and solemnity, we may be certain; and vocal, say they, was preferred to instrumental, and the lyre to the flute, not only for its decency and gravity, but because instruction could be conveyed to the mind, by means of articulation in singing, at the same time as the ear was delighted by sweet sounds. This was said to have been the opinion of Minerva. In very high antiquity mankind gave human wisdom to their gods, and afterwards took it from them, to bestow it on mortals.

In perusing the list of illustrious men, who have sprung from the school of Pythagoras, it appears that the love and cultivation of music was so much a part of their discipline, that almost every one of them left a treatise behind him upon the subject.

PYTHAGORAS'S Table. See Table.

PYTHAGOREA, in Botany, received that appellation from Loureiro, in memory of the famous Pythagoras, who is said to have written a book on the qualities of plants.—Loureir. Cochinchin. 243. Clafs and order, Othandria Tetragyna. Nat. Ord. . . .

Gen. Ch. Cal. Periarch inferior, bell-shaped, of seven or eight linear, hairy, coloured leaves. Cor. inferior, bell-shaped, of seven or eight lanceolate, concave, hairy petals, the length of the calyx. Stam. Filaments eight, awl-shaped, longer than the corolla; anthers roundish, two-lobed. Pfl. German between the calyx and corolla, nearly ovate, hairy; style four, awl-shaped, reflexed, shorter than the flumes; stigmas acute. Peric. Capsule ovate, of four cells. Sclers numerous, roundish.

Eff. Ch. Calyx of seven or eight leaves, inferior. Corolla of seven or eight petals, superior. Capsule of four cells, with many seeds.

1. P. cochinchinensis.—Native of Cochinchina, where it is called Xiang cá tía nbo lâi. A small tree, with numerous branches. Leaves nearly sessile, ovo-lanceolate, serrated, smooth; their longitudinal ribs red at the extremity. Chyfters axillary, long, nearly simple, with short partiafl stalks. Flowers white.

Such is Loureiro's account, but we have no knowledge of the plant he describes, nor can we offer any conjecture respecting its natural affinity. We have no faith in the existence of a herm superior to the calyx and inferior to the corolla, the only influence of the kind which Linneus ever imagined, in Sanguinaria, proving not well founded.

PYTHAGOREAN, or PYTHAGORIC System, among the Ancients, was the name with the Copernican system among the moderns. See System.

It was thus called, as having been maintained and cultivated by Pythagoras, and his followers; not that it was invented by him, for it was much older.

PYTHAGOREANS, a sect of ancient philosophers, who adhered to the doctrine of Pythagoras.

Pythagoras, the founder of this sect, was of Samos, the son of a lupidary, and a pupil of Pierceydes, and flourished (says Bayle) about five hundred years before Christ, in the time of Tarquin, the last king of Rome, and not in Numa's time, as many authors have supposed. See Cicer. Tufcul. Quodt. lib. iv. cap. 1.

The time of his birth, however, has been much disputed. Dr. Bentley, in his "Dissertation on the Epistles of Phalaris," relying chiefly on the authority of Eratosthenes, refers the birth of Pythagoras to the fourth year of the 43rd Olympiad, B.C. 628. Lloyd, in his "Dissertation concerning the Chronology of Pythagoras," ascribes his birth to the 3rd year of the 48th Olympiad, B.C. 586. Dodwell places it in the 4th year of the 52d Olympiad, B.C. 569, relating in this date chiefly on the authority of Porphyry and Jamblichus. Upon the whole, the opinion of Lloyd seems to be the most probable, which is, that he was born about the year B.C. 586, and that he died about the 3rd year of the 68th Olympiad, B.C. 506; so that it seems pretty certain, that he was not born earlier than the 4th year of the 43d Olympiad, B.C. 605, nor later than the 4th year of the 52d, B.C. 569. If we admit only the credible particulars of his childhood and early education, and pay no attention to the tales of Jamblichus and others, who even asserted that he was the son of God, we shall find that he was first instructed in his own country by Creophilus, and afterwards by Pierceydes, in the island of Sicyrus, and that after having paid his last tribute of respect to his preceptor, he returned to Samos, and purged his fludes under the direction of his first master. Jamblichus, and other later biographers, mention his journey into Ionia, and his interviews with Thales and Anaximander, but of this journey we have no authentic record, nor is any effect of it discernible in his doctrine, which is essentially different from that of the Ionian school. His first journey from the Greek islands was probably into Egypt, which was celebrated in his time for that kind of wisdom which bell futed his genius and temper. In his way thither, Jamblichus affirms that he visited Phaenicia, and conversed with the prophets and philosophers that were the predecessors of Mochus the Physiologist; which Mochus, Semon, and many others, have been to Mole.

Nor is it thought at all improbable that Pythagoras might with to acquaint himself with the Phoenician philosophy, of which he must, without doubt, have received a general report from his father, and from other merchants who traded to this coast. But that he derived his knowledge of numbers from the Phoenicians is not at all probable, because their acquaintance with numbers extended no further than 5 to
PYTHAGOREANS.

...to the practical science of arithmetic. It has been said, indeed, that Pythagoras travelled, not only into Egypt and Chaldaea, but even into the Indies, to inform his understanding with regard to all branches of science and prevalent customs; and that after returning to his own country, being unable to bear the tyranny of Polycrates, he retired into the eastern part of Italy, there called Magna Graecia, and established his sect, denominated from this circumstance the "Italic Sect," or "Italic school." Whatever opinion is entertained of this journey to the East, to which Le Clerc gives no credit, we must altogether reject other stories of his visiting the temple on mount Carmel, and remaining there for several days, without food, palling among the inhabitants for a good daemon, and obtaining from them religious honours; and of his proceeding into India, and there palling through several ceremonies of the Mofaic law.

Pythagoras, whilst he was in Egypt, was introduced by the recommendation of Polycrates, tyrant of Samos, to Amasis, king of Egypt, a distinguished patron of literary men, and thus obtained access to the colleges of the priests. Having found it difficult to gain this privilege, he performed many severe and troublesome preliminary ceremonies, and even submitted to circumcision, a preferred condition of his admission. He palled twenty-two years in Egypt, availing himself of all possible means of information with regard to the recondite doctrines of the Egyptian priests, as well as their astronomy and geometry, and Egyptian learning in its most unlimited extent.

Many writers of reputation, both Pagan and Christian, who flourished after the commencement of the Christian era, relate, that after Pythagoras had left Egypt, he visited the Persian and Chaldaean Magi, and proceeded so far as to have intercourse with the Indian Gymnosophists. Jamblichus affirms, that he was taken captive by the viceroy of the island of Cambyles, and carried to Babylon, where he acquainted himself with the learning and philosophy of the East; and that after the expiration of twelve years, when he was in the 60th year of his age, he returned to Samos. The circumstance of his having visited the Persian magic is also mentioned by Cicero, Eusebicus, Laëntius, and Valerius Maximus, though they take no notice of his captivity. In this journey to the East, as some have maintained, he attended upon the instructious of the celebrated Persian sage, Zoroaster; and others, who have placed the life of Zoroaster in an earlier period than that of Pythagoras, have alleged, that he conversed with certain Jewish prophets, who were at that time in Babylon, in a state of captivity, and thus became acquainted with the Jewish laws and customs. However, several objections, particularly of a chronological kind, have been alleged against the narrative of Pythagoras's journey to the East. Chronologists unanimously agree, that Cambyses invaded Egypt in the fifth year of his reign, or the third year of the 63d Olympiad. According to Jamblichus, Pythagoras, after palling twelve years in Babylon, and visiting several other countries, went into Italy in the 62d Olympiad. The same date is affixed to this journey by Diodorus and Clemens Alexandrinus; whilst others place it about fourteen years earlier. Hence it appears, that if Pythagoras left the East before the 62d Olympiad, after remaining there twelve years, he could not have been carried thither by Cambyses in the 63d Olympiad. Moreover, the whole narration of Pythagoras's journey into the East is contradicted by the express authority of Antiphon (quoted by Porphyry), who says that Pythagoras, after his residence in Egypt, returned into Ionia, and opened a school in his own country; and that, at the age of forty years, finding himself harried by the tyranny of Polycrates, he withdrew into Italy; and according to this account, we have no interval for the supposed eastern expedition. The reality of this expedition is testified either by certain Alexandrian Platonists, who were deficient of exalting, as much as possible, the wisdom of those ancient philosophers, whom they considered as the oracles of wildom, or by certain Jewish and Christian writers, who were disposed to credit every tale which tended to give probability to the opinion that the Pythagorean doctrine was derived from the Oriental philosophers, and ultimately from the Hebrew scriptures. In either case the authenticity of the relation is liable to just suspicion; nor is there any probable argument to prove, that Pythagoras received instruction from any prophet of the Hebrew nation, during his supposed residence at Babylon. Brucker concurs with those writers who are disposed to reject this story of Pythagoras's eastern journey as a mere fiction, and who concludes that, having never palled from Egypt to the East, he returned thence immediately to Samos. The story of his having visited the northern Druids is so delusive of probability and of evidence, as to merit no regard.

After his return from Egypt to his native island, he wished to communicate the benefit of his twenty years' researches and studies to his fellow-citizens, and with this view he attempted to inftitute a school for their instruction in the elements of science; proposing to adopt the Egyptian mode of teaching, and to communicate his doctrines under a symbolical form; but the Samians were either too stupid or too indolent to profit by his instructions. Although he was obliged to relinquish his design, he did not altogether abandon it. In order to engage the attention of his countrymen by some other means, he repaired to Delos; and having received an offering of cakes to Apollo, he there received, or pretended to receive, moral dogmas from the priests, which he afterwards delivered to his disciples under the character of divine precepts. With the same views he also visited the island of Crete, to celebrated in mythological history; where he was conducted by the Corybantes, or priests of Cybele, into the cave of mount Ida, in which Jupiter is said to have been buried. Here he conversed with Epimenides, an eminent pretender to prophetic powers, and was by him initiated into the most sacred mysteries of Greece. About the same time he visited Sparta and Elis, and was present during the celebration of the Olympic games, where he is said to have exhibited a golden thigh to Abaris, in order to convince him that he was Apollo. Besides other places which he visited during his stay in Greece, he repaired to Phlius, where he first assumed the appellation of philosopher. (See Philosopher.) Having thus added to the stores of learning which he had previously accumulated, and acquired a kind of authority which was calculated to command respect, he returned to Samos, and made a second attempt, more successful than his first, for establishing a school of philosophy. In a semicircular kind of building, which the Samians had used as a place of resort for public business, he delivered with an assumed authority of a sacred nature, popular precepts of morality; and he also provided for himself a secret cave, into which he retired with his intimate friends and professed disciples, and here he gave his followers daily instructions, accompanied with a considerable parade of mystery, in the more abstruse parts of philosophy. His fame, and the multitude of his followers, increased. What he failed to accomplish by the mere force of learning and ability, he effected by concealing his doctrines under the veil of mysterious symbols, and infusing forth his precepts as refpomies from a divine oracle. About the beginning of the 59th Olympiad, Pythagoras, deficient of escaping...
the tyrannical government exercised in his native island by Syphax, the brother of Polycrates, left Samos, and, as we have already hinted, passed over into Italy, and attempted to establish his school among the colonies of Magna Græcia. It is probable that, in order to obtain credit with the populace, he about this time pretended to possess a power of performing miracles, and practised many arts of imposture. The first place at which he arrived in Italy was Crotona, a city in the bay of Tarentum, the inhabitants of which were very corrupt in their manners. But such were his reputation and influence, that he was treated with great respect; and people of all classes assembled to hear his discourses; insomuch that the manners of the citizens were soon totally changed from great luxury and licentiousness to strict sobriety and frugality. It is said that 600 (some say 2000), persons were prevailed upon to submit to the strict discipline which he required, and to throw their effects into a common stock for the benefit of the whole fraternity. The influence of his philosophy extended from Crotona to many other cities of Magna Græcia, and obtained for Pythagoras from his followers a degree of respect little short of adoration. If he had contended himself with delivering doctrines of philosophy and precepts of practical wisdom, he might probably have continued his labours, without molestation, to the end of his life. But he manifested a strong propensity towards political innovations; and he employed his influence in urging the people to the frenzied assertion of their rights, against the encroachments of their tyrannical governors. This course of conduct raised against him a very powerful opposition, which he was unable to repel and contend against, and which obliged him to retire to Metapontum. Here he found himself still surrounded with enemies, and was under a necessity of seeking an asylum in the temple of the Muses, where, not being supplied by his friends with sufficient food, he perished with hunger. The time of his death is uncertain; but according to the Chronicle of Eusebius, he died in the third year of the 68th Olympiad, B.C. 506, after having lived, according to the most probable statement of his birth, to the age of 80 years. After his death his followers paid a superfluous respect to his memory. They erected statues in honour of him, converted his house at Crotona into a temple of Ceres, the street in which it stood was called the Museum, and appealed to him as a divinity, swearing by his name.

It appears, from the history of this philosopher, that with all his talents and learning, he owed much of his celebrity and authority to imposture. His whole manner of life confirms this opinion. Clothed in a long white robe, with a flowing beard, and, as some say, with a golden crown on his head, he preferred among the people, and in the presence of his disciples, a commanding gravity and majesty of aspect. He recurled to music for promoting the tranquillity of his mind, frequently singing, for this purpose, hymns of Thales, Herod, and Homer. He had such an entire command over himself, that he was never seen to express, in his countenance, grief, joy, or anger. He refrained from animal food, and confined himself to a frugal vegetable diet, excluding from his simple bill of fare, for mythical reasons, pulse or beans. By this artificial demeanour, Pythagoras appeared among the vulgar as a being of an order superior to the common condition of humanity, and perfused them that he had received his doctrine from heaven. Pythagoras married Theano of Crotona; or, as some say, of Crete, by whom he had two sons, Telephus and Mnesarchus, who, after his death, took the charge of his school. Whether this philosopher left behind him any writings has been a subject of dispute. Many works have been enumerated under his name by Laertius, Jamblichus, and Pliny; but it is the declared opinion of Plutarch, Josephus, Lucian, and others, that there were no genuine works of Pythagoras extant; and it appears highly probable, from the pains which he took to confine his doctrine to his own school during his life, that he never committed his philosophical system to writing, and that the pieces to which his name is affixed at an early period, were written by some of his followers, upon the principles imbibed in his school. The famous golden verses attributed to Pythagoras, and illustrated with a commentary by Hierocles, were not written by our philosopher, but are to be ascribed to Epicharmus, or Empedocles. They may, however, be considered as a brief summary of his popular doctrines.

His "Method of Instruction," formed upon the Egyptian model, was "exoteric," and "esoteric," that is, public and private. Those auditors, who attended his public lectures, did not properly belong to his school; but followed their usual mode of living. His select disciples, called his companions and friends, were such as submitted to a peculiar plan of discipline, and were admitted, by a long course of instruction, into all the mysteries of his esoteric doctrine.

Previously to the admission of any person into this fraternity, Pythagoras examined his features and external appearance; inquired how he had been brought up, and the conduct of his parents and friends; marked his manner of laughing, conversing, and keeping silence; and observed what passions he was most inclined to indulge; with what kind of company he chose to associate; how he passed his leisure moments; and what incidents appeared to excite in him the strongest emotions of joy or sorrow. Nor after this examination was any one admitted into his society, till he was fully persuaded of the docility of his disciple, the gentleness of his manners, his power of retaining in silence what he was taught, and, in fine, his capacity of becoming a true philosopher. After the first probationary admission, the fortitude and self-command of the candidate were put to the trial by a long course of severe abstinence and rigorous exercise. The course of abstinence and selfish denial comprehended food and drink, and clothing, all which were of the most plain and simple kind: and the exercices prescribed were such as could not be performed without pain and fatigue. To teach them humility and industry, he exposed them, for three years, to a continued course of contradiction, ridicule, and contempt, among their fellows. In order to restrain the powerful passion of avarice, he required his disciples to submit to voluntary poverty; and deprived them of all command over their own property, by calling the possessions of each individual into a common stock, to be distributed by proper officers, as occasion required. After this liquidation of their goods, they lived together on the footing of perfect equality, and fat down together daily at a common table. If any one afterwards repented of the connection, he was at liberty to depart, and might reclaim, from the general fund, his whole contribution. That his disciples might acquire a habit of entire docility, Pythagoras enjoined upon them, from their first admission, a long term of silence, called by the Greeks, a theke, or a season. This initiatory silence, which probably consisted in refraining from speech, not only during the hours of instruction, but through the whole term of initiation, continued from two to five years, according to the propensity discovered by the pupil towards conceit and loquacity. With regard to himself, this was a judicious expedient, as it checked impertinent curiosity, and prevented every inconvenience of contradiction. Accordingly his disciples silenced all doubts and refuted all objections,
PYTHAGOREANS.

Dejections, by appealing to his authority. And, in the presence of the members, decided every dispute. Moreover, during the years of initiation, the disciples were prohibited from seeing their master, or hearing his lectures, except from behind a curtain, or receiving instruction from some inferior preceptor.

To the members of the esoteric school (who were called 
Pythagoreans, genuine disciples) belonged the peculiar privilege of receiving a full explanation of the whole doctrine of Pythagoras, which was delivered to others in brief percepts and dogmas, under the concealment of symbols. Disciples of this class were permitted to take minutes of their master's lectures, in writing, as well as to propose questions, and offer remarks, upon every subject of discourse. These were particularly distinguished by the appellation of the "Pythagoreans;" they were also called "Mathematicians," from the studies upon which they entered immediately after their initiation. After having made a sufficient progress in geometrical science, they proceeded to the study of nature, the investigation of primary principles, and the knowledge of God. Those who pursued these sublime speculations were called "Théorists," and those who devoted themselves more particularly to theology, were styled "Theœoi," religious. Others, according to their abilities and inclinations, were engaged in the study of morals, economics, and policy; and were afterwards employed in managing the affairs of the fraternity, or sent into the cities of Greece, to instruct them in the principles of government, or affix them in the institution of laws.

The brethren of the Pythagorean college at Crotona, called 
Pythagoreans, about 600 in number, lived together as in one family, with their wives and children; and the whole band of the society was conducted with the most perfect regularity. Each day commenced with deliberation upon the manner in which it should be spent; and concluded with a retrospect of the events that had occurred, and of the business that had been transacted. They rode before the fun, that they might pay him homage; after which they repeated select verses from Homer and other poets, and made use of music, both vocal and instrumental, to enliven their spirits and fit them for the business of the day. They then employed several hours in the study of science. These were succeeded by an interval of leisure, which was commonly spent in a solitary walk for the purpose of contemplation. The next portion of the day was allotted to conversation. The hour immediately before dinner was filled up with various kinds of athletic exercises. Their dinner consisted chiefly of bread, honey, and water; for after they were perfectly initiated, they wholly denied themselves the use of wine. The remainder of the day was devoted to civil and domestic affairs, conversation, bathing, and religious ceremonies.

The "exoteric" disciples of Pythagoras were taught, after the Egyptian manner, by images and symbols, obscure and almost unintelligible to those who were not initiated into the mysteries of the school; and those who were admitted to this privilege were under the strictest obligation of silence with regard to the recondite doctrines of their master. The wisdom of Pythagoras, that it might not pass into the ears of the vulgar, was committed chiefly to memory; and when they found it necessary to make use of writing, they took care not to suffer their minutes to pass beyond the limits of the school.

Clemens observes, that the two orders above described corresponded very exactly to those among the Hebrews; for in the schools of the prophets there were two classes, 
that of the sons of the prophets, who were the scholars; and the doctors or masters, who were also called "perfects;" and among the Levites, the novices or tyros, who had their quinquennial exercises, by way of preparation. Lastly, even among the profelytes there were two orders: 
"exoteric," or profelytes of the gate; and "intricati vel perfecti," profelytes of the covenant. He adds, it is highly probable, that Pythagoras himself had been a profylete of the gate, if not of the covenant.

Gale endeavours to prove, that Pythagoras borrowed his philosophy from that of the Jews; to this end producing the authorities of many of the fathers, and ancient authors; and even pointing out the tracks and footsteps of Moses in several parts of Pythagoras's doctrine.

After the dissolution of the assembly of Pythagoras, his disciples by the faction of Cyrus, a man of wealth and distinction at Crotona, it was thought necessary by Lyias and Archiphus, in order to preserve the Pythagorean doctrine from oblivion, to reduce it to a systematic summary; at the same time, however, strongly enjoining their children to preserve these memoirs secret, and to transmit them in confidence to their posterity. From this time books began to multiply among the followers of Pythagoras, till at length, in the time of Plato, Philolaus expounded the Pythagorean records to the multitude, and Archytas of Tarentum gave Plato a copy of his commentaries upon the aphorisms and precepts of his master. Of the imperfect records of the Pythagorean philosophy left by Lyias, Archytas, and others, nothing has escaped the wreck of time, except perhaps fragmentary collections by the diligence of Stobæus, concerning the authenticity of which there are some grounds for suspicion; and which, if admitted as genuine, will only exhibit an imperfect view of the moral and political doctrine of Pythagoras under the disguise of sibylline and enigmatical language. The strict injunction of secrecy, which was given by oath to the initiated Pythagoreans, has effectually prevented any original records of their doctrine concerning Nature and God from falling down to posterity. On this head we are to rely entirely for information, and indeed concerning the whole doctrine of Pythagoras, upon Plato and his followers. Plato himself, while he enriched his system with fragments from the magazine of Pythagoras, accommodated the Pythagorean doctrines, as he also did the theses of his master Socrates, to his own system, and thus gave an imperfect, and, we may fancy, in many particulars, a false representation of the doctrines of the Samian philosopher. It was further corrupted by the followers of Plato, even in the old academy, and afterwards in the Alexandrian school. To which we may add, that the doctrine of Pythagoras itself, probably in its original state, and certainly in every form under which it has been transmitted to us, was observed, not only by sibylline, but by mathematical language, which is rather adapted to perplex than to illustrate metaphysical conceptions. In this fault Pythagoras was afterwards imitated by Plato, Aristotle, and others.

We extract from Brucker the following faint delineation of the Pythagorean philosophy: The end of philosophy is to free the mind from those incumbrances, which hinder its progress towards perfection, and to raise it to the contemplation of immutable truth, and the knowledge of divine and spiritual objects. This effect must be produced by easy steps, left the mind, hitherto conversant only with sensible things, should revolt at the change. The first step towards wisdom is the study of mathematics, a science which contemplates objects that lie in the middle way between corporeal and incorporeal beings, and as it were on the confines of both, and which most advantageously inures the mind to contemplation,
PYTHAGOREANS.

contemplation. The whole course of mathematical science may be divided into four parts: two respecting numbers, and two respecting magnitude. Number may be considered either abstracledly in itself, or as applied to some object. The former science is arithmetic; of the latter kind is magnitude. Magnitude may be considered as at rest, or as in motion; the science which treats of the former is geometry, that which treats of the latter is astronomy. Arithmetic is the noblest science; numbers the first object of study, and a perfect acquaintance with numbers the highest good. Numbers are either scientific or intelligible.

Scientific number is the production of the powers involved in unity, or the progression of multitude from the monad or unity, and its return to the same. Unity and one are to be distinguished from each other; the former being an abstract conception, the latter belonging to things capable of being numbered. Number is not infinite, but is the source of that infinite divisibility into equal parts, which is the property of all bodies.

Intelligible numbers are those which subsisted in the divine mind before all things, from which everything hath received its form, and which always remain immitably the same. It is the model, or archetype, after which the world, in all its parts, is framed. Numbers are the cause of concurrence to beings: \( \tau \xi \kappa \alpha \iota \varphi \iota \lambda \omega \nu \kappa 
\]

The monad, or unity, is that quantity, which, being deprived of all number, remains fixed; whence called monad, from \( \tau \varepsilon \omicron \mu \omicron \acute{a} \nu \). It is the fountain of all number. The duad is imperfect and passive, and the cause of increase and division. The triad, composed of the monad and duad, partakes of the nature of both. The tetrad, tetractys, or quaternion number, is the most perfect. The decad, which is the sum of the four former, comprehends all arithmetical and musical proportions.

According to some writers, the monad denotes the active principle in nature, or God; the duad, the passive principle, or matter; the triad, the world formed by the union of the two former; and the tetractys, the perfection of nature. Some have understood by this mysteriously number, the four elements; others, the four faculties of the human mind; others, the four cardinal virtues; and others have been so absurd as to suppose that Pythagoras made use of this number to express the name of God, in reference to the word \( \gamma \nu \alpha \gamma \gamma \gamma \), by which that name is expressed in the Hebrew language. But every attempt to unfold this mystery has hitherto been unsuccessful.

The most probable explanation of the Pythagorian doctrine of numbers is, that they were used as symbolical or emblematical representations of the first principles and forms of nature, and particularly of those eternal and immutable essences, to which Plato afterwards gave the appellation of Ideas. Not being able, or not chusing, to explain in simple language the abstract notions of principles and forms, Pythagoras seems to have made use of numbers, as geometrical figures, or numbers, diagrams, to assist the conceptions of scholars. More particularly, conceiving some analogy between numbers and the intellectual forms which subsist in the divine mind, he made the former a symbol of the latter. As numbers proceed from unity, or the monad, as a simple root, whence they branch out into various combinations, and assume new properties in their progress, so he conceived the different forms of nature to proceed, at different distances, from their common source, the pure and simple essence of deity, and at every degree of distance to assume certain properties in some measure analogous to those of number; and hence he concluded, that the origin of things, their emanation from the first being, and their subsequent progression through various orders, if not capable of a perfectly clear explanation, might, however, be illustrated by symbols and resemblances borrowed from numbers.

Next to numbers, music had the chief place in the preparatory exercises of the Pythagorean school, by means of which the mind was to be raised above the dominion of the passions, and inured to contemplation. Pythagoras considered music, not only as an art to be judged of by the ear, but as a science to be reduced to mathematical principles and proportions. We have introduced, under the article PYTHAGORAEAN, the manner in which he is said to have discovered the musical chords, but shall here subjoin a more minute account. As Pythagoras was one day reflecting upon the subject, happening to pass by a smith's forge, where several men were successively striking with their hammers a piece of heated iron upon an anvil, he remarked, that all the sounds produced by their strokes were harmonious except one. The sounds, which he observed to be chords, were the octave, the fifth, and the third; but that sound which he perceived to lie between the third and the fifth he found to be discordant. Going into the work-shop, he observed, that the diversity of sounds arose, not from the form of the hammers, nor from the force with which they were struck, nor from the position of the iron, but merely from the difference of weight in the hammers. Taking, therefore, the exact weight of the several hammers, he went home, and suspended four strings of the same substance, length, and thickness, and twined in the same degree, and hung a weight at the lower end of each, respectively equal to the weight of the hammers: upon striking the strings, he found, that the musical chords of the strings corresponded with those of the hammers. Hence it is said, that he proceeded to form a musical scale, and to construct musical instruments. His scale was, after his death, engraved in braze, and preserved in the temple of Juno at Samos.

Pythagoras conceived that the celestial spheres in which the planets move, striking upon the ether through which they pass, must produce a sound; and that this sound must vary, according to the diversities of their magnitude, velocity, and relative distance. Taking it for granted, that every thing respecting the heavenly bodies is adjusted with perfect regularity, he further imagined, that all the circumstances necessary to render the sounds produced by their motion harmonious, were fixed in such exact proportions, that the most perfect harmony is produced by their revolutions. This fanciful doctrine respecting the music of the spheres gave rise to the names which Pythagoras applied to musical tones. The last note in the musical octave he called hypate, because he supposed the sphere of Saturn, the highest planet, to give the deepest tone; and the highest note he called scate, from the sphere of the moon, which being the lowest, or nearest the earth, he imagined, produced the shrillest sound. In like manner of the reed. It was said of Pythagoras by his followers, who heeded at no allusion, however improbable, which might seem to exalt their master's fame, that he was the only mortal so far favoured by the gods as to be permitted to hear the celestial music of the spheres. Pythagoras applied music to the cure of diseases both bodily and mental. It was, as we have seen, the element of his school, to compose their minds for rest in the evening, and to prepare themselves for action in the morning, by suitable airs, which they performed upon the lyre, or other stringed instruments. The music was, however, always accompanied with verse, so that it may be doubted, whether the effect was to be ascribed more to the musical or
or to the poet. It is said of Clinius, a Pythagorean, that whenever he perceived himself inclined to anger, spleen, or other reflefs passions, he took up his lute, and that it never failed to restore the tranquility of his mind. Of Pythagoras himself it is related, that he checked a young man, who, in the midst of his revels, was meditating some act of Bacchanalian madness, by ordering the musician, who had inflamed his passions by Phrygian airs, to change the music on a sudden into the slow and solemn Doric mood. If the stories which are related by the ancients concerning the wonderful effects of their music are to be credited, we must acknowledge we are strangers to the method by which these effects were produced.

Besides arithmetic and music, Pythagoras cultivated geometry, which he had learned in Egypt; but he greatly improved it, by investigating many new theorems, and by digesting its principles, in an order more perfectly systematic than had before been done. Several Grecians, about the time of Pythagoras, applied themselves to mathematical learning, particularly Thales in Ionia. But Pythagoras seems to have done more than any other philosopher of this period towards reducing geometry to a regular science. His definition of a point is, a monad or unity with position. He taught that a geometrical point corresponds to unity in arithmetic, a line to two, a superficies to three, a solid to four. Of the geometrical theorems ascribed to Pythagoras, the following are the principal: that the interior angles of every triangle are together equal to two right angles; that the only polygons which will fill up the whole space about a given point, are the equilateral triangle, the square, and the hexagon; the first to be taken six times, the second four times, and the third three times; and that, in rectangular triangles, the square of the side which subtends the right angle is equal to the two squares of the sides which contain the right angle. Upon the invention of this latter proposition (Euclid, I. i. prop. 47.), Plutarch says, that Pythagoras offered an ox, others, an hecatomb, to the gods. But this story is thought by Cicero inconsistent with the institutions of Pythagoras, which, as he supposes, did not admit of animal sacrifices. Pythagoras inferred the stature of Hercules from the length of the Olympic scourge, which measured six hundred of his feet. Observing how much shorter a croufe six hundred times the length of the foot of an ordinary-man was than the Olympic scourge, he inferred, by the law of proportion, the length of Hercules's foot; whence the actual proportion of the length of the foot to the height of a man enabled him to determine the problem. Pythagoras also applied geometrical ideas as symbolical expressions of bodies, and of natural principles; but nothing certain, or intelligible, is preserved on this head.

On astronomy, the doctrine of Pythagoras, or, however, of the ancient Pythagoreans, was as follows: The term heaven either denotes the sphere of the fixed stars, or the whole space between the fixed stars and the moon, or the whole world, including both the celestial spheres and the earth. There are ten celestial spheres, nine of which are visible to us; namely, that of the fixed stars, those of the seven planets, and that of the earth; the tenth is the antichthon, or invisible sphere opposite to the earth, which is necessary to complete the harmony of nature, as the decad is the completion of numerical harmony. And this antichthon may be the cause of the greater number of the eclipses of the sun than of the moon. Fire holds the middle place in the universe; or, in the midst of the four elements is placed the fiery globe of unity; the earth is not without motion, nor situated in the centre of the spheres, but is one of those planets which make their revolution about the sphere of fire. The revolution of Saturn is completed in thirty years, that of Jupiter in twenty, that of Mars in two, that of the Sun, and of Mercury and Venus, in one year. The distance of the several celestial spheres from the earth correspond to the proportion of notes in the musical scale. The moon and other planetary globes are habitable. The earth is a globe, which admits of antipodes.

From several of these particulars respecting the astronomical doctrine of Pythagoras, it has been inferred, that he was poffessed of the true idea of the solar system, which was revived by Copernicus, and has since been fully established by Newton.

From this preparatory study the disciples of the Pythagorean school were conducted to the knowledge of natural, theological, and moral science. Concerning wisdom, in general, Pythagoras taught, that it is the science which is convertible with those objects, which are in their nature immutable, eternal, and incorruptible, and therefore alone can properly be said to exist. The man who applies himself to this kind of study is a philosopher. The end of philosophy is, that the human mind may, by such contemplation, be assimilated to the divine, and at length be qualified to join the assembly of the gods. In the pursuit of wisdom, the utmost care must be taken to raise the mind above the dominion of the passions, and the influence of fallible objects, and to diffuse it from all corporeal impressions, that it may be inured to converse with itself, and to contemplate things spiritual and divine. For this purpose the allusion of God, and of good demons, must be invoked by prayer. Philosophy, as it is convertible with speculative truth, or with the rules of human conduct, is either theoretical or practical. Practical philosophy is only to be studied so far as may be necessary for the purposes of life; theoretical philosophy is the perfection of wisdom. Contemplative wisdom cannot be completely attained, without a total abatraction from the ordinary affairs of life, and a perfect tranquility and freedom of mind. Hence the necessity of instituting a society, separated from the world, for the purpose of contemplation and study.

Active or moral philosophy, which prescribes rules and precepts for the conduct of life, according to Aristotle, was first taught by Pythagoras, and after his death by Socrates. Among the moral maxims and precepts ascribed to Pythagoras are the following: Virtue is divided into two branches, private and public. Private virtue respects education, silence, abstinence from animal food, fortitude, sobriety, and prudence. The powers of the mind are reason and passion; and when the latter is preferred in subjection to the former, virtue is prevalent. Young persons should be inured to subjection, that they may always find it easy to submit to the authority of reason. Let them be conducted into the belt course of life, and habit will soon render it the most pleasant. Silence is better than idle words. A wise man will prepare himself for every thing which is not in his own power. Do what you judge to be right, whatever the vulgar may think of you; if you despise their praised, despise also their censure. It is inconsistent with fortitude to relinquish the honour appointed by the Supreme Lord, before we obtain his permission. Sobriety is the strength of the soul, for it preserves its reason unclouded by passion. No man ought to be esteemed free, who has not the perfect command of himself. Drunkenness is a temporary phrenzy. That which is good and becoming is rather to be pursued, than that which is pleasant. The desire of superfluity is foolish, because it knows
PYTHAGOREANS.

no limits. All animal pleasures should rather be postponed than enjoyed before their time; and should only be enjoyed according to nature, and with sobriety. Much forethought, in and discretion is necessary in the production and education of children. Wifdom and virtue are our best defenses; every other guard is weak and unstable. It requires much wifdom to give right names to things.

Concerning public virtue, the doctrine of Pythagoras, as it is transmitted to the present time, respects conversation, friendship, religious worship, reverence to the dead, and legislation. Upon these heads he is said to have taught that:

Conversation should be adapted to the characters and condition of the persons with whom we converse; that discourse and behaviour, which might be proper among young persons, may be exceedingly improper between the young and aged. Propriety and seafonableness are the first things to be regarded in conversation. In all society, a due regard must be had to subordinotion. Respect is due to a worthy stranger, sometimes in preference even to countrymen or relations. It is better that those who converse with you should respect you, than that they should fear you; for respect produces admiration, but fear produces hatred. It is an evident proof of a good education, to be able to endure the want of it in others. Between friends, the utmost care should be taken to avoid contention, which can only be done by humbling as much as possible all occasions of strife, suppressing resentJnent, and exercising mutual forbearance. Reproof and correction are useful and becoming from the elder to the younger; especially when they are accompanied, on the part of the reprover, with evident tokens of affection.

Mutual confidence is never for a moment to be interrupted between friends, whether in jest or earnest; for nothing can heal the wounds which are made by deceit. A friend must never be forfaken in adversity, nor for any infirmity in human nature, excepting only invincible obstinacy and depravity. Before we abandon a friend, we should endeavour, by actions as well as words, to reclaim him. True friendship is a kind of union which is immortal.

The design and object of all moral precepts is to lead men to the imitation of God. Since the Deity directs all things, every good thing is to be sought for from him alone; and nothing is to be done which is contrary to his pleasure. WhiUst we are performing divine rites, piety should dwell in the mind. The gods are to be worshipping not under such images as represent the forms of men, but by such symbols as are suitable to their nature, by simple lustrations and offerings, and with purity of heart. Gods and heroes are to be worshipped with different degrees of homage, according to their nature. Oaths are in no case to be violated.

The bodies of the dead are not to be burned. Next to gods and demons, the highest reverence is due to parents and legislators; and the laws and customs of our country are to be religiously observed.—Thus much concerning the active or moral philosophy of Pythagoras.

Theoretical philosophy, which treats of nature and its origin, was the highest object of study among the Pythagorean school, and included all those profound mysteries, which thefe, who have been ambitious to report what Pythagoras said behind the curtain, have endeavored to unfold. Upon this subject, nothing can be advanced with certainty, excepting the theology, the doctrine of which, Pythagoras, after the manner of the Egyptian priests, was particularly careful to hide under the veil of symbols, probably through fear of disturbing the popular superstitions. The ancients have not, however, left us without some grounds of conjecture.

With respect to God, Pythagoras appears to have taught, that he is the Universal Mind, diffused through all things, the source of all animal life, the proper and intrinsic cause of all motion, in subsance similar to light, in nature like truth, the first principle of the univerfe, incapable of pain, invisible, incorruptible, and only to be comprehended by the mind.

Cicero (Nat. Deor. l r. c 12.) affirms, that Pythagoras conceived God to be a fool pervading all nature, of which every human soul is a portion: and this doctrine was perfectly consonant to the opinions received in the countries which Pythagoras visited, and where he learned theology. Julius Martyr (Orat. ad Genes) expressly ranks Pythagoras among the thetical philosophers. "If any one," says he, "wishes to be informed more accurately concerning the doctrine of Pythagoras with respect to one God, let him hear his opinion, for he says, God is one; he is not, as some conjecture, exterior to the world, but, in himself entire, pervades the universal sphere,superintends all productions, is the support of all nature, eternal, the source of all power, the first simple principle of all things, the origin of celestial light, the father of all, the mind and animating principle of the univerfe, the first mover of all the spheres." From a variety of passages that might be cited, we may reasonably infer, that Pythagoras conceived the Deity to be the informing soul of the world, animating it in a manner similar to that in which the human soul animates the body.

Subordinate to the Deity, it was taught in the Italic school, that there are three orders of intelligence, gods, demons, heroes, who are distinguished by their respective degrees of excellence and dignity, and by the nature of the homage which is due to them; gods being topreferred in honour to demi-gods or demons, and demons to heroes or men. These three orders, in the Pythagorean system, were emanations, at different degrees of proximity, from the supreme intelligence, the particles of subtle ether assuming a grofer clothing the farther they receded from the fountain. The third order, or heroes, were supposed to be invested with a subtle material clothing. Hierocles defines a hero to be a rational mind united with a luminous body. If to these three species we add a fourth, the human mind, we have the whole scale of divine emanation, as it was conceived by this sect of philosophers. All these imaginary to proceed from God, as the first fount of intelligence, and to have received from him a pure, simple, immutable nature. God, being himself one, and the origin of all divinity, they represented him under the notion of monad, and subordinate intelligences, as numbers derived and included in unity. Thus the numbers or derived intelligences of Pythagoras agree with the ideas of Plato, except, perhaps, that the latter were of a nature perfectly spiritual, but the former were clothed with a subtle ethereal body.

The region of the air was supposed by the Pythagoreans to be full of spirits, demons, or heroes, who cause sickness or health to man or beast, and communicate, at their pleasure, by means of dreams, and other instruments of divination, the knowledge of future events. That Pythagoras himself held this opinion cannot be doubted, if it be true, as his biographers relate, that he professed to cure diseases by incantations. It is probable that he derived it from the Egyptians, among whom it was believed that many diseases were caused by demoniacal possessions.

The material world, according to Pythagoras, was produced by the energy of the divine intelligence. It is an animated sphere, beyond which is a perfect vacuum. It contains
containing spheres, which revolve with musical harmony. The atmosphere of the earth is a gross, immutable, and morbid mass; but the air, or ether, which surrounds it is pure, healthful, serene, perpetually moving, the region of all divine and immortal natures. The sun, moon, and stars, are inhabited by portions of the divinity, or gods. The sun is a spherical body. Its eclipses are caused by the passing of the moon between it and the earth; those of the moon by the intervention of the antichthon, before explained. The moon is inhabited by demons. Comets are stars, which are not always seen, but rise at stated periods.

Concerning man, the Pythagoreans taught, that, consisting of an elementary nature, and a divine or rational principle, he is a microcosm, or compendium of the universe; that his soul is a self-moving principle, composed of two parts, the rational, which is a portion of the soul of the world, seated in the brain, and the irrational, which includes the passions, and is seated in the heart; that man participates in both these with the brutes, which, from the temperance of their body, and their want of the power of speech, are incapable of acting rationally; that the nomothetic soul, $\psi_{\omega}$, perishes, but the rational mind, $\zeta_{\omega}$, is immortal, because the fonsence when it is derived is immortal; that after the rational mind is freed from the chains of the body, it affumes an ethereal vehicle, and pales into the regions of the dead, where it remains till it is sent back to this world, to be the inhabitant of some other body, brutal or human; that after suffering successive purgations, when it is sufficiently purified, it is received among the gods, and returns to the eternal fonsence from which it first proceeded.

The doctrine of the Pythagoreans, respecting the nature of brute animals, and $\mu_{\nu} \nu \omega \lambda \nu \xi \omega$, the transmigration of souls, were the foundation of their abstinence from animal food, and of the exclusion of animal sacrifices from their religious ceremonies. The latter doctrine is thus beautifully represented by Ovid, who introduces Pythagoras as saying:

"Morte carent animae: semperque priore reliqua
Sede, novis domibus habitant, vivuntque receptae.
Omnia mutantur; nil habet interi; errat et illinc,
Huc venit, hinc illuc, et qui subiectum occupat artus.
Spiritus, quae fersis humanae in corpora transit,
Inque feras noftræ: nec tempore deteripulo uter,
Utque novis fragilis signatur cera figuris,
Nec manet ut fuerat, nec formas futuræ eadem,
Se dentem ipsa eadem eit, animam lic februm eadem
Elfe, fed in varias doceo migrare figuras."

"What then is death, but ancient matter dreft
In some new figure, and a varied veil?
Thus all things are but alter'd, nothing dies;
And here and there the unbodied spirit flies,
By time, or force, or sickness dispossessed,
And lodges where it lights, in man or beast;
Or hunting without, till ready limbs it find,
And actuates those according to their kind;
From tenement to tenement is told;
The fons is still the fame, the figure only loth:
And as the fofen's wax new fels receives,
This face affumes, and that impression leaves;
Now call'd by one, now by another name,
The form is only chang'd, the wax is still the fame;
So death, thus call'd, can but the form deface,
Th' immortal soul flies out in empty space,
To seek her fortune in some other place."

DYREN.

This doctrine Pythagoras probably learned in Egypt, where it was commonly taught. Nor is there any sufficient reason for understanding it, as some have done, symbolically.

Among the symbols of Pythagoras, recited by Jamblichus and others, are the following: Adore the sound of the whispering wind. Stir not the fire with a sword. Turn aside from an edged tool. Pafs not over a balance. Setting out on a journey, turn not back, for the furies will return with you. Breed nothing that hath crooked talons. Receive not a swallow into your house. Look not in a mirror by the light of a candle. At a sacrifice, pare not your nails. Eat not the heart, or brain. Taste not that which hath fallen from the table. Break not bread. Sleep not at noon. When it thunders, touch the earth. Pluck not a crown. Roll not that which has been boiled. Sail not on the ground. Plant not a palm. Breed a cock, but do not sacrifice it, for it is sacred to the sun and moon. Plant mallows in thy garden, but eat them not. Abstain from beans.

The precept prohibiting the use of beans, is one of the mysteries which the ancient Pythagoreans never divulged, and which modern ingenuity has in vain attempted to discover. Its meaning was probably rather dictatorial, than physical, or moral. But enough of these enigmatical trife. Pythagorean precepts of more value are such as these: Discourse not of Pythagorean doctrines without light. Above all things govern your tongue. Engrave not the image of God in a ring. Quit not your station without the command of your general. Remember that the paths of virtue and of vice resemble the letter Y. To this symbol Periplus refers, when he says,

"Et tibi que Samios diduxit litera ramos,
Surgentem dextro monitrix limite collem."

"There has the Samian Y's instructive make
Pointed the road thy doubtful foot should take;
There warn'd thy raw and yet unpractis'd youth,
To tread the rising right-hand path of truth."

Brucker's Hist. Philos. by Enfield, vol. i. b. 2. c. 12.

After the death of Pythagoras, the care and education of his children, and the charge of his school, devolved upon Aristeus of Crotonia, who, having taught the doctrine of Pythagoras 39 years, was succeeded by Mnæarchus, the son of Pythagoras. Pythagorean schools were afterwards conducted in Hermelion, by Cleonidas and Philolaus; at Metapontum, by Theorides and Eurypus; and at Tarentum, by Archytas, who is said to have been the eighth in succession from Pythagoras. The first person who divulged the Pythagorean doctrine was Philolaus; see his article.

PYTHAGORIC ABACUS. See Abacæ and Table.

PYTHAGORIC TETRAHY. See Tetractys.

PYTHAGORIC THEOREM, or Proposition, is the 47th of the first book of Euclid. See Triangle and Hypotenuse.

PYTHEAS, in Biography, an ancient mathematician, astronomer, and geographer, was a native of the Greek colony of Marcella, in Gaul, and flourished in the time of Aristotle and Alexander the Great. He contributed to the improvement of science by accounts which he wrote of his travels and voyages, and other works. To him is attributed a book, entitled $\psi_{\omega} \xi_{\omega} \zeta_{\omega}$, or the circuit of the earth; and in the abridgment of Artemidorus the Ephesian, he is placed in the number of those who have written a

"Periplus"
PYT

"Periplus of the World," and he is supposed to have written a treatise "De Oceano," none of these pieces have reached modern times, though some of them were extant in the fourth century. From fragments collected out of Strabo, it appears that Pytheas introduced into them, as the testimony of others, a number of marvellous and incredible circumstances, which drew on him the censure of that author and Polybius. The last named author maintained it to be utterly impossible for a private person, who was even in want, to have travelled so far as he pretended to have done by sea and land. He, however, probably visited all the countries of Europe that are situated upon the ocean, discovered the island of Thule, or Iceland, and penetrated a considerable distance into the Baltic. This fact has been proved by Galfendi, who shews, that Pytheas was well acquainted with the northern countries, and accurately marked the distinction of climates, by the difference which he observed in the length of the days and nights in different latitudes. He also attempts to prove that Eratosthenes and Hipparchus improved their geographical works by availing themselves of the labours of Pytheas, without due acknowledgments of their obligations. There is no doubt that Pytheas was a skilful observer of the heavens, for he taught that there is no star in the precise situation of the pole, and he rendered himself famous among astronomers, by being the first calculator of the meridian altitude of the sun at the summer solstice at Marcellis. This fact he ascertained by erecting a gnomon of a given height, and finding the proportion between that height and the length of the meridian shadow. The result was found to correspond exactly with that of an observation made by Galfendi, at the same place, in the year 1656. To obviate such objections as that advanced by Polybius against the reality of Pytheas' voyages, it has been said, that he probably was furnished with the means of procuring them at the public expense. For as the republic of Marcellis was then powerful at sea, largely engaged in commercial pursuits, and sent Euthymenes to make such discoveries in the southern parts of the world, as might lead to the extension of its trade, it seems very probable, that Pytheas was dispatched on the public account into the northern regions for the fame purposes.

PYTHEUM, in Ancient Geography, a town of Macedonia, in the country of the Paeonians. Ptolemy places it between Azorium and Gonumus.

PYTHIA, or PYTHIAN, in Antiquity, the priestesses of Apollo, by whom he delivered oracles. See DELPHOS.

She was thus called from the god himself, who was entitled Apollo Pythius, from his slaying the serpent Python; or, as others will have it, Г;ς η ψιθις, because Apollo, the first, is the cause of rottenness; or because the carcase of Python was left there to putrefy; or, according to others, from πυθιαδες, I enquire, because people went to hear and consult his oracles.

This priestess was to be a pure virgin. She sat on the coverle, or lid, of a brazen vessel, mounted on a tripod; before she ascended which, after fasting three days, she used to wash her whole body, and especially her hair, in Castalia, a fountain at the foot of Parnassus, where the poets, men inspired by the same deity, used to wash, and drink; and thence, after shaking the laurel-tree that grew by it, and sometimes eating the leaves, which were supposed to conduct to inspiration, and were succeeded by a violent enthusiasm, she delivered her oracles, or rather explained those of the god; i. e. she rehearsed a few ambiguous and obscure verses, which were taken for oracles. The oracle being pronounced, she was taken down from the tripod and conducted back to her cell, where she continued for several days, to recover herself from the violent agitation and confusion. Lucan informs us, that speedy death was frequently the consequence of her enthusiasm. See ORACLE.

Diodorus Siculus (lib. xvi.) informs us, that these priestesses were at first virgins, but that after one of them was delivered by Echeocrates, a Thessalian, choice was made of women above fifty years of age; that so they might either be secured from the attempts of lust, or if they should at any time be forced to the violation of their chastity, having passed the time of child-bearing, they might remain undiscovered, and not bring the oracles or religion into contempt; nevertheless they wore the habit of virgins, whereby to signify their purity and virginal modesty.

All the Pythiae did not seem to have had the same talent at poetry, or to have memory enough to retain their leonon. Plutarch and Strabo make mention of poets, who were kept in pay, as interpreters of Jupiter, &c.

PYTHIA, or PYTHIAN Games, were solemn games instituted in honour of Apollo, and in memory of his killing the serpent Python with his arrows.

The Pythiae were celebrated in Macedonia, in a place called Pythium. They were next in name after the Olympic games, but were more ancient than they; for it is pretended they were instituted immediately after the defeat of the serpent. The Pythiae were also celebrated at Delphi; and they were thefe that were the most renowned. Their first founder, and the precise time of their institution, are not known.

The Pythian games, according to Paulaniers, were first instituted by Jason or Diomedes, king of Eotia, and restored by Eurylochus of thefaly, in the third year of the 48th Olympiad, or the year of the world 3364, and 584 years before the birth of Christ; from which time the Greeks reckoned sometimes by Pythiades, as they had been accustomed to do by Olympiads. They were at first celebrated every eight years, but afterwards every four years, in the third year of each Olympiad; so that the pythiad, which was a term of four years, served as an epocha for the inhabitants of Delphi. At firl, they consisted of poetical and musical contests, but in process of time they confined of the other exercizes of the pantcramium, which were performed in the Olympic games. The victors were crowned with branches of laurel; though, at the first institution, the crown was of beech-leaves. The Romans are said to have adopted these games in the year U.C. 642, and to have given them the name of Apollinares ludi.

A part of Pindar's poems was composed in praise of the victors in the Pythian games. See GAMES.

The critics are divided on the subject of the serpent Python. The poets say, that Juno made use of it to persecute Latona, and prevent her bringing into the world Apollo and Diana, whom she had conceived of Jupiter; and that it was for this reason that Apollo afterwards killed it.

Strabo says, it was no other than a famous villain, one Draco, that Apollo freed the world from. Dickinon, in his "Delphi Pheniciares," maintains the Python of the Greeks to be the Typhon of the Phenicians; and the Typhon of the Phenicians to be the Og of Scripture; and Apollo, who slew it, he will have to be Jofhua. See TYPHON.

PYTHON, in Ancient Geography, a name anciently given to the city of Delphi.

PYTHOPOLIS, a town of Asia Minor, in Bithynia, on the river Soloonte, according to Plutarch, founded by Thefeus.
PYX

Thecus.—Allo, a town of Aupa Minor, in Caria; afterwards called Nysa.—Allo, a town of Acast in Mycia.

PYULCON, from πυλς, πυς, and λέω, to draw, an old surgical instrument anciently employed for drawing the matter out of ulcers.

PYURIA, in Medicine, from πυερ, πυς, and υρα, υρις, a term used by Sauvages and others to denote all purulent and mucous discharges from the bladder. See CATAURUS Vefcre.

PYXIDANTHERA, in Botany, from πυξις, a box, and σάνθης, an anther, becaufe, according to Michaux, each cell of the anthers opens by a fort of lid; see Diapensia, to which genus the plant in question is referred by Mr. Pursh, in his Fl. Amer. Sept. v. 1, 148, under the name of D. canadensis, after Mr. Salisbury.

PYXIS NAUTICA, in Navigations, the feaman's compass.

The word πυξις, literally signifies a box.

Pyxis, among Anatolics, is also used for the cavity of the hip-bone. See ACETABULUM.

PYXIS, a small metal case for containing the consecrated species in the Catholic church. Anciently it was made in the form of a dove and suspended over the altar.

PYXUS, in Ancient Geography, a small river of Italy, in Lucania; which took its rise northward towards Sonia, and running southward discharged itself into a gulf of the same name, E. of Pyxus, or Pyxontum.

Pyxus, or Pyxontum, Poli-Caffro, a town of Italy, belonging to Lucania, situated at the bottom of a small gulf, E. of a small river of the same name. It was founded by Mirathus, prince of Zanele and Rhegium, in the year 471 B.C. It became a Roman colony in the year 194 before the same era.

Pyxus Promontorium, a small cape of Italy, E. of a peninsula of Lucania, which had on the W. the promontory Palinurum. This promontory is found at the entrance of a small gulf of the same name.

PZINENIN, in Geography, a town of Bohemia, in the circle of Bohemia; 12 miles E. of Jung-Duntz.

Q.

Q, a confonant, borrowed from the Latin or French, for which the Saxons generally used cp, c; and the sixteenth letter of the alphabet.

The name of this letter is cur, from queur, Fr. tail; its form being that of an O with a tail. It is therefore reckoned among the mutes.

The Q is formed from the Hebrew, ק, kaph; which most other languages have borrowed; though some of them have rejected it again, particularly the Greeks, who now only retain it as a numeral character, called κεντυς επικεφαλος.

In effeet, there is that resemblance between the Q and the C, in some languages, and the K in others, that many grammarians, in imitation of the Greeks, banish the Q as a superfluous letter. Papas even affirms, that all the Latin words now wrote with a Q, were written among the ancient Romans with C; but we want better authorities for this. For, though that may hold in many cates, infomuch that some write indifferently quier, or cur; cum, or quum; quotidie, or cotidie, &c. yet it does not thence follow, that they ever wrote cur, cur, cur, cur. What inscriptions authorize such a reading?

Far from this, the ancients sometimes substiuited Q for C; and wrote quoiquis, qui, for cuius, cui, &c.

Varro, however, and some other grammarians, as we are told by Censorinus, &c. would never use the Q. The truth is, its use or dilute feems to have been fo little settled, and agreed on, that the poets used the Q or C indifferently, as belt suited their measures; it being a rule, that the Q joined the two following vowels into one syllable; and that the C imported them to be divided.

Hence it is, that Lucretius uses cuiet for three syllables, in lieu of quiete; acus, for aquis; and that Plautus uses relicium, for reliquum; as in quod dedil, datum non vellem reliquum.

Vol. XXIX.

non; where the cuum must be two syllables, otherwise the trochaic verse will be lame of a foot.

In the French, the sound of the Q and K are so near a kin, that some of their neeqt authors think the former might be spared. Ramus adds, that, till the eltablifment of royal professors in the university of Paris, under Francis I. they always used Q in the Latin the same as in the French; pronouncing his, kalis, kantu, &c. for quis, qualis, quantus. See K.

Some very learned men make Q a double letter, as well as K and X. According to them, Q is evidently a C and U joined together. It is not enough that the sound of the same is the same, but they see the traces of the C U in the figure of the Q; the V being only laid obliquely, so as to come within the cavity of the C; as c <.

To confirm this, they say the ancients wrote qu, qu, qui. Though Jof. Scaliger, Littlenfon, &c. think this is no proof of the point; for in Gruter's inscriptions we find not only the Q, but alfo the C, put for QU; as Cintus, Quintus; fecis for fquis, &c. Yet nobody ever imagined the C a double letter.

Q, among the Ancients, was a numeral letter, signifying 500; as in the verse,

"Q velut A cum D quingentos vult numerare."

A daal over it, as Ò, denoted it to signify five hundred thousand.

Q is also used as an abbreviation in several arts. Q, pl. in physicians' bills, stands for quantum place, or quantum vi, as much as you please of a thing; q. f. for quantum sufficit, or as much as is necellary.

Q, in the proper names of the Romans, signifies Quintus, or Quintius. Upon the French coins this letter denotes that they were struck at Perpignan.
QUA

Q. feems the initial of no word in Nuptn, except in old madrigals, where it frequently is placed at the top of the page for quinta pars, the fifth part, in a polyphonic composition. Q. D. is frequently used, among Grammarians, &c. for qua® d®tm, as if it were laid, &c. or as who should say. Q. E. D. among Mathematicians, signifies qua® erat demon®strandum, which was to be demonstrated.

Q. E. F. qua® erat faciendum, which was to be done.

QUAB, in Ichthyology, the name of a Ruffian kind, which some report to be at first a tadpole, then a frog, and at last a fish. Dr. Mooney, who made many enquiries concerning their pretended changes, apprehends that they are all fabulous. He had an opportunity of seeing the fish itself, and found that they spawned like other fishes, and grew in size, without any appearances to justify the report. He adds, that they delight in very clear water, in rivers with sandy or stony bottoms, and are never found in running lakes, or in rivers palling through marshy or muddy grounds, where frogs choicest mott to be. Phil. Tans. vol. siv. p. 175.

QUABES, in Geography, a people of Africa, in the interior country between Rio Seillos and Sierra Leona, inhabiting the southern banks of the river Seillos. They had been formerly conquered by Plancus, king of Folgia; but having thrown off their subjection, they have since remained a free people, though under the protection of the emperor of Moesia, or Moanus; which empire is called English geographers, and E. by M. d'Aville, Mendi Manow.

QUACHA, or QUAGGA, in Zoology. See Equus.

QUACHILTO, in Ornithology, the name of a very beautiful Brazilian bird, of the moor-hen kind, called also paca-cuial, and porphyrio Americanus. It is the Fulica Purpurea, (which fee.) and is of a fine blackish purple colour, variegated with white; its beak is white while young, but becomes red as it grows older, and has a naked space at its base, resembling, in some fort, the coot; its legs are of a yellowish-green; it lives about the waters and feeds on fish, yet is a very well-tailed bird. It imitates the crowing of a common cock, and makes its musical carly in the morning. Marggrave's Hill. Brasil.

QUACHY, in Zoology, a name given to the Coatis, or Viverra Naia; (which fee.)

QUACK, in Medicine. See Empiric.

QUACKENBRUCK, in Geography, a town of Welfphalia, in the bishopric of Olufibruck, situated on the river Hase, which runs through it in seven streams, that unite in two below the town; 20 miles N. of Olufibruck. N. lat. 52° 42'; E. long. 8° 3'.

QUADIANs, Quad, in Ancient Geography, a people of Germany, whose territories extended from the Danube to Moravia, and the northern part of Austria. They are comprehended by some writers under the ancient name of Suevi, part of whom forced their way into Spain, and formed a kingdom there. Their country is at present known by the name of Moravia; for it extended from the mountains of Bohemia to the river Murus, now the March, and consequently comprised that province. Ptolemy mentions the following cities in the country of the Quadians: viz. Eburodumum, Eburum, Medaclanum, and Clemantia, now, according to Cluverius, Broi, Olmutz, Znain, and Kalmintz. The Quadians were a warlike people, had kings of their own, and agreed in customs, manners, and religion, with the other German nations. They, without doubt, joined their countrymen against Lollia, Germanicus, Caius, and Galba, who attempted to reduce Germany, and to subdue the several nations which inhabited that extensive country. The emperor Domitian marched against them, but was defeated by the Marcomanns, and put to flight. The Quadians submitted to the emperor Titus Antoninus, and it appears by his coins, suppos'd to have been struck about the year 139, that they acknowledged, as sovereign, a king appointed by that prince. They joined the Marcomans, in the infamous war made by that people on the empire under the reign of Marcus Aurelius; but being reduced to great distresses, they sent ambassadors to sue for peace, and with them they restored all the Roman defaters, and about 15,000 prisoners, whom they had taken during the war. They thus obtained peace, upon condition, that they should not traffic, for the future, within the Roman dominions, nor settle within six miles of the Danube; but, disliking these conditions, they again joined the Marcomans, and renewed the war. In the prosecution of this contest, which was long and fanguinary, they were totally defeated by their Emperor Ariogades, and taken prisoners; but the emperor spared his life, confining him to the city of Alexandria, the metropolis of Egypt. The Quadians, however, seem to have continued in arms till the reign of Commodus, who granted them peace upon the following terms: that they should keep at the distance of five miles from the Danube; that they should surrender their arms, and supply the Romans with a certain number of troops when required; that they should assemble but once a month in one place, and in the presence of a Roman centurion; and that they should not make war upon the neighbouring countries without the consent of the people of Rome. In the year 214, the king of the Quadians was Gaibomar, who was affiliated by order of Caracalla. In the 4th year of the reign of the emperor Valerian, the Quadians joined the Sarmatians, and invaded Illyricum, raving that province; but they were defeated by Probus, then tribune of a legion, and afterwards emperor. In the year 260, the 7th of the emperor Gallienus, they made an sudden irruption into Panonia, but they were expelled, without their booty, by Regillianus. Upon the death of Probus, who had kept the barbarians in awe, A.D. 283, the Quadians, in connexion with the Sarmatians, broke into Illyricum and Thrace, and having ravaged those provinces, and advancing towards Italy, they were met by Carus, the successor of Probus, on the borders of Illyricum, and totally defeated; 16,000 being killed on the spot, and 25,000 being taken prisoners. In the 19th year of the emperor Constandius, the Quadians made an irruption into Panonia and Mecca; and having pillaged both provinces, returned home with an immense booty. They returned again in two years, and laid waste Valeria. Constandius was provoked by these invasions, and leaving Milan, advanced to the confines of the Quadians, and conferred with their chiefs, who excused past hostilities, and promised, for the future, to live in peace and unity with the emperor. They soon, however, forgot their promise; and in the following year joined the Sarmatians, and laid waste Valeria. Constandius, at the approach of Constandius, they repulsed the Danube, and returned home. The emperor determining to punish them for their treachery, called the Danube on a bridge of boats, and began to destroy their country. The Quadians, unable to resist, fled for peace, and obtained it, upon delivering up hostages, and setting at liberty all the prisoners they had taken. In the year 374, their king Gabinus being treacherously murdered by Marcellinus, duke of Valeria, they crossed the Danube in the utmost rage, and falling upon the reapers, in harvett time, killed the greatest number of them, laid waste the country, and took many captives. They afterwards followed Equius, general of the troops in Illyricum, who had been
Quadangular figures are not proper for fortification; the flanks, and flanked angles, being too small.

Quadrangular Figures, the Square-fish, in Ichthyology, the name of a fish, which, in its most usual size, is about fifteen inches long, four inches high in the middle, and three inches and a half over; the forehead is square, a little hollowed, and, by the eminence of the eye-brows, two inches and a half over; the nose blunt, and not very deep, with two holes in the place of nostrils, and the mouth very small; the back is a little convex toward the tail, and on the sides a little obliquely angled; as is also the belly, which is plain and flat, and a little rising toward the tail; it has five fins, two near the gills, two near the tail, and the tail-fins, which is considerably long. Part of the head and tail are covered with a soft skin, the rest of the body with a kind of crust, adorned all over with little round knots, reduced for the most part into hexagonal figures, and subdivided into equaliteral triangles. Grew, Muf. Reg. Sac. p. 110.

Quadranis, in Antiquity, the fourth part of the as, or pound. See As.

Quadranis, in our Caftems, is the fourth part of a penny; or a farthing.

Quadrant, Quadrans, in Geometry, an arc of a circle, containing 90 degrees, or one-fourth of the entire periphery.

Sometimes, also, the space, or area, included between this arc and two radii, drawn from the centre to each extremity thereof, is called a quadrant, or, more properly, a quadrantal space; as being a quarter of the entire circle.

Quadrant also denotes a mathematical instrument, of great use in navigation and astronomy, for the taking of altitudes, angles, &c.

The quadrant is variously contrived, and furnished with different apparatus, according to the several uses for which it is intended; but they have all this in common, that they consist of a quadrant, or quarter of a circle, whose limb is divided into 90 degrees; and that they have a plummet suspended from the centre; and are furnished with pinhole or sights, through which to look.

Quadrant, the Common, or Surveying, (represented Plate VI. Surveying, fig. 13.) is made of brass, wood, or other matter, usually twelve or fifteen inches radius. Its circular limb is divided into 90, and each of those subdivided into as many equal parts as the space will allow, either diagonally or otherwise. On one edge, or semi-diameter, are fixed two moveable sights; and in the angle, or centre, is hung a thread, with a plummet. To the centre is likewise, sometimes, fixed a label, or moveable index, bearing two other sights, like the index of a telescope. And, in lieu of the immovable sights, there is sometimes fitted a telescope; though this more peculiarly belongs to the astro-nomical quadrant.

On the under side, or face, of the instrument, are fitted a ball and socket; by means of which it may be put in any position, for use.

Besides the essentials of the quadrant, there is frequently added on the face, near the centre, a kind of compartment, called the quadrat, or geometrical figure; as in the figure; this, in some measure, making a distinct instrument of itself. See its description and use under the article Quadrat.

The quadrant is to be used in different situations, according to the dimensions to be taken. To observe heights and depths, its plane is disposed at right angles to the horizon; but to take horizontal distances, the plane is disposed parallel to it.

Heights and distances, again, may be taken two ways;
Thus fall to angles an 54° contact and the wood, always degrees that therefore place the but edges but not portion fattened, ftrike the the wood, of the quadrant, of the instrument to the object, e. gr. the top of a tower, till the visual rays of it strike through the fights upon the eye.

This done, the portion of the arc intercepted between the thread and the fermidiameter, on which the fights are fattened, fhwes the complement of the object's height above the horizon, or its distance from the zenith; and the other portion of the arc intercepted between the thread and the other fermidiameter, fhwes the height itself of the object above the horizon.

The fame arc likewise gives the quantity of the angle made by the visual ray, and a horizontal line, parallel to the base of the tower.

Note, to obferve depths, the eye must be placed over that fight next the centre of the quadrant.

From the height or depth of the object in degrees thus found, wefume 33° 35'; and the distance of the feet of the object from the place of obfervation carefully meafured, which fuppose 47 feet; its height or depth in feet, yards, &c. is easily determined by the most common cafe in trigonometry.

For we have here, in a triangle, one fide given, viz. the line meafured, and we have all the angles; for that of the tower is always fupposed a right angle: the other two, therefore, are equal to another right angle; but the angle obferved is 35° 35', therefore the other is 54° 25'.

The cafe, then, will be reduced to this as the line of 54° 25' is to 47 feet, fo is the line of 35° 35' to a fourth term, viz. 33 3/4 feet; to which add the height of the obferver's eye, fuppose 5 feet; and the fum, 38 1/4 feet, is the height of the tower required.

Quadrant, the further use of the, in taking of altitudes of objects, both accessifable and inaccessible, fee under the article Altitude.

Quadrant, Use of the, in taking heights and diftances by the index and fights.—To take, e. gr. a height, as that of a tower whose base is accessifable; place the plane of the instrument at right angles to the plane of the horizon, and one of its edges parallel to it, by means of the plummet, which, in that cafe, will hang down along the other. In this fitution turn the index, till, through the fight, you fee the top of the tower; and the arc of the limb of the quadrant between that fide thereof parallel to the horizon and the index will be the height of the object in degrees; whence, and from the diftance meafured as before, its height in feet, &c. may be found by calculation, as in the former cafe: or, without calculation, by drawing from the data, on paper, a triangle fimilar to the great one, whose base is the diftance; and its perpendicular, meafured on the scale, is the height of the tower.

Quadrant, Use of the, in meafuring horizontal diftances.—Though the quadrant be a lefs proper instrument for this purpofe than a theodolite, femicircle, or the like, because angles greater than quadrants cannot be taken by it, yet accessifity sometimes obliges perions to have recourse to it.

The manner of its application is the fame with that of the femicircle; all the difference between the two instruments confifling in this, that the one is an arc of 180°, and can therefore take an angle of any quantity; and the other is only an arc of 90°, and is therefore confined to angles of that quantity. See, therefore, Semicircle.

Quadrant, in Astronomy, is an instrument by which the altitude of a heavenly body is meafured, and is composed of one-quarter, or one-eighth of a circle, accordingly as the meafurement is made by means of direct vision, or by the reflected image of the object to be viewed. When a fuffled circle was made use of with revolving fights, called an affrolabe, the accuracy of an obfervation could never be depended on, partly because the radius was small, and partly because the instrument vibrated when fuffled by the hand, and was otherwife inconvenient to use, as well as liable to have its equirome disturbed by the various poifitions of the index and fights: therefore, fich a portion of the circle was adopted as was competent to meafeure the greateft poifible altitude, and an increafe of radius was thereby obained, which promifed to contribute to accuracy, without affecting the portability of the instrument. But though the construction was varied by different ingenious men, the quadrant was but little, if at all, conducive to the improvement of nautical or of aeronautical science, till the application of telefopic fights, and an improved mode of graufating the limb, together with the addition of a vernier cafe, gave it powers on which the mariner and aeronomer could confide. Quadrants have been conftructed of different materials, fuch as wood, ivory, brafa, &c. and of various dimensions, agreeably to the ufe for which they were intended, in order to accommodate purchasers of every denomination; but as it is not our province to notice every plaything that has unfurped the appellation of quadrant, we will confine our account to fuch instruments chiefly as have been of actual service in navigation and aeronomy. We have, however, already anticipated the history, we might here have introduced, of the various improvements succesfively made in quadrants, at the beginning of our article Circle; and under the article Graduation we have given, at considerable length, the different methods of dividing and subdividing astronomical instruments in general; to which articles we beg to refer our readers, who will for information on thoje points, and which may be read in conjunction with our present article.

Our arrangement of quadrants will be most fystematic, if we divide them into two claffes, viz. thefe which meafeure altitudes by direct vision, and thefe which determine meafurements in all directions, vertically, horizontally, and obliquely, by means of reflection. The former claffes have been found useful in aeronomy chiefly, and the latter in navigation, where the motion of a fhipируется with the readiness of any fixed poifition of an instrument.

The firft quadrant, in its conftruction, was f probabiy a quarter of the affrolabe enlarged, with fixed fights placed in, or parallel to, the vertical line pafling through zero; and a line thread, or wire, ftrretched by a plummet, indicated the altitude on the divided limb, according to the representation in figure 4, of Plate 1, of Aeronomical Instruments. This contruction might be used in obfervations of the fun, without injuring the eye of the obfserver, by allowing the folar ray to pafl through the firft fight-vane, or hole, to as to fall on the second, at fome diftance from the firmer, while the thread rolled nearly in contact with the elevated limb; but the want of minute, and at the fame time accurate fubdivisions, and the fensitive thickness of the thread, were impediments to accuracy that did not admit of remedy, until another mode of reading the altitudes was devis'd, and until a method was contrived of rendering the light of the fun tolerable to the eye of an obfserver. The former of these defiderata was accomplished firft by diagonal fcales, with a fiducial edge of an index, and afterwards by that admirable contrivance, fometimes called a Nomius, but more properly denominat'd a Vernier, from the name of its inventor;
ventor; the latter was effected by semi-opaque glafs, introduced at first without, but afterwards, with better effect, with telescopic sights; at the same time, enlarging the visual angles subtended by the fun, and yet diminishing the intensity of his light by a partial transmission through the frosted or coloured glafs.

**Davis's Quadrant, or Back-Staff.**—In the year 1590, captain John Davis, a native of Sandridge, near Dartmouth, previously to his falling into the South seas under the command of Mr. Cavendish, contrived that instrument, which is represented in fig. 2, of Plate I. of Astronomical Instruments, and which has been called the English quadrant, or back-staff. This instrument diffentled with the ufe of the plumeline, and consequently was better adapted to nautical purpofes than the old quadrant, or than the fore-staff, that preceded it; but wanted the telefcope fights, which have given ftubfentient instruments the advantage over it. It was, however, probably the ftirft quadrant in which the horizon was ufed as one of the objects in a back obfervation, and from which the reftcftent inftruments afterwards borrowed an ufeful principle, where altitudes are concerned; though it was in the ufe of the fore-staff, (derecribed under our article CIRCLE,) that the horizon was ftirft made one of the extreme limits of an altitude, taken by a forward obfervation.

Captain Davis found that pear-tree answered very well as the material on which his instrument was conftucted, and an ingenious arrangement of two divided arcs and three vannes confifted his plan, according to the following description. The vane at A was called the horizon-vane; the one feen at B the shade-vane, because its shadow fell on the horizon-vane during the inftant of completing an obfervation; and the third, at C, was denominated the fight-vane, by reafon of its being the vane to which the eye was applied in taking an obfervation. The arc of smaller radius, D E, contained 60°, and the other, F G, of larger radius, contained only 30°, in combination of the former, making together the whole quadrant. The arc D E was divided into whole degrees only, on account of the finmallness of its radius; but the arc F G had its degrees divided by concentric and diagonal lines, as seen in the figure. The manner of ascertaining the altitude of a heavenly body, by the joint ufe of these two arcs, is not obvious at first sight of the inftrument, but may be thus explained. When the altitude of the fun is taken, the horizon-vane is fized to the extreme end or centre A of the quadrant, and the shade-vane B is put to within about 10° or 15° of the supposed co-altitude, but at a lefs quantity than the obferver, while the fight-vane remains for adjustment on the arc F G. Things being in this ftate, the back of the obferver is turned to the fun, and the quadrant is fo elevated, that the shadow of the upper edge of the shade-vane B falls upon the upper edge of the slit in the horizon-vane A, when viewed through the small hole in the fight-vane. If now, in this situation, the horizon is feen through the fap slit, the obfervation is exact; but if not, the fight-vane is moved backwards or forwards on the arc F G, accordingly as the sky or fun is feen, till the horizon appears in its place, while the shadow of the shade-vane refts on the required line in the slit of the horizon-vane, and then the obfervation is finifhed; and the fun of the two readings on the repective arcs, B and C, as read by the fiducial edges of the vannes, is the co-altitude or zenith distance of that limb of the fun, upper or lower, which was observed from the corresponding limb of the shadow. If a lens, of a focal length equal to the radius of the smaller arc, were ufed, the focal luminous point occasioned thereby would be a better object to measure the place of, than a shadow with an edge not sufficiently defined. This instrument, it should feem, was not capable of taking the altitude of a star or planet, nor of the moon, unless her disc was large enough at the time to project a shadow.

**Elton's Quadrant.**—An index bearing a spirit-level, with a vernier scale near the fight-vane, was added to the quadrant of Davis some time afterwards, by one Elton, the ufe of which was to take altitudes without an horizon; but the similarity of the two inftruments renders a more particular defcription of this addition superfluous. An infpection of fig. 8. Plate I. will sufficiently explain the difference.

**Gunter's Quadrant.**—Among the numerous and ufeful contrivances of the ingenious professor of altronomy in Guelfham college, was a portable quadrant, which now claims our attention, and which was contrived in, or a little before, the year 1618. The object of the inventor was not to construct an inftrument capable of measuring altitudes more accurately than that of captain Davis, which we have juft defcribed, but to make a quadrant fo comprehensive in its ufe, that, like the logarithmic scale, which he divided, it might fliew by infpection results, which had previously required long and tedious calculations; and in this point of view it is still to be confidered. Besides the quadrantal arc for measuring altitudes, this inftrument has various curves Stereographically projected on it, such as the equator, the tropics, the ecliptic, and the horizon, on a fuppoftion that the eye is fited in one of the poles, all which are represented in fig. 3. of Plate XXIII. of Astronomical Instruments. The projection, according to Bion, is thus efrected; when the quadrantal arc BC has been graduated, from its centre A, with a convenient radius AT, describe the arc TD to repreft one of the tropics; and let the line AT be taken as the tangent of 56° 40', or half the fun's greatest declination (suppofed here to be 23° 32'), added to the radius of tangent of 45°; then to find the point E in this line for the equinoctial, there will be this proportion, as the tangent of 56° 40': 1000 :: radius: 055; and therefore, if the parts of the line AT be taken, it will be the proper radius of the arc EF, or equinoctial.

To find the centre of the occult arc ED, which repreft the ecliptic, let the meridional line AD be fo divided by the point G, that if AG be taken as radius, AG may be the tangent of 23° 32', the fun's greatest declination; in which cafe AG will be the arc of the line AF, and the occult arc ED defcribed from the point G will be one-fourth of the ecliptic, which may be divided into signs and degrees thus: as radius is to the tangent of any degree's diftance from the nearest equinoctial point, fo is the co-line of the sun's greatest declination, to the tangent of that degree's right afcension; for example, suppofting the right afcension of the first point of A to be 27° 54', draw a line from A, the centre of the quadrantal arc, to this degree and minute on the faid arc, and note where it interfefts the occult arc of the ecliptic, and this point will be the beginning of the sign G; and in like manner any other part may be inferted.

The line ET, or line of declination, may be divided thus; taking AE for the radius of the equinoctial, or tangent of 45°, let the tangents of 46°, 47°, 48°, &c. up to 68° 30', be succesfively taken and laid down on the line ET, and the points of excess above the tangential point of 45° will be the dividing lines of the scale for 1°, 2°, 3°, &c. up to 23° 32', or greatest declination.

When the fcale of declination is finifhed, the quadrantal arc may be taken as the meafure of right afcensions, and then the place of a star or any other heavenly body may be inferted on the plane of the quadrant thus; let a line be drawn
QUADRANT.

drawn from A to the degree and minute of right ascension, counted from B towards C, and the point in this line, where an occult arc, drawn through the declination from the centre A, intercepts it, will be the place of the heavenly body in question.

The two parallel arcs contained between the tropic D and the quadrantal arc BC, are the scales of days and months, which are divided by the aid of a table of meridian altitudes of the sun for each day, calculated for the particular latitude, for which the quadrant is constructed. It is hardly necessary to observe, on the construction of such a table, that if the latitude and declination be both north, or both south, the declination must be added to the co-altitude for the greatest altitude; but if of contrary denominations, substracted. The degrees and minutes contained in such a table are transferred into the scale of months by a line extending across it from the centre A to the quadrantal arc as before.

The centre of the horizon will be in the meridional line AC, and if a point H be taken such, for the co-altitude 38° 28′ for instance, that AH may be the corresponding tangent to radius AF, then \( \frac{1}{4} \) of that radius will be its distance from A, and the arc subtended by the extent HE, beginning at E in the equinoctial, and ending at the tropic D, will be the required horizon. This horizontal arc may be divided thus, as radius is to the line of the latitude, so is the tangent of any number of degrees in the horizon, to the tangent of a corresponding arc in the quadrant; and from a table thus constructed any point in the horizon may be put in by interpolation of a line drawn from A to the tabular number as read on the quadrantal arc, as in the former cases.

A third table of the sun's altitude for inferring the hour lines may be calculated thus; when the sun is in the equator, as radius is to the co-altitude of the latitude, so is the line of the latitude, to the tangent of a fourth arc; then if the latitude and declination have like denominations, and the hour fall between noon and fix o'clock, substract the declination from the said fourth arc, and the remainder will be a fifth arc; but if the latitude and declination have unlike denominations, or the hour be between six and midnight, add the declination to the fourth arc, and the fun will be a fifth arc, which must be thus used; as the line of the fourth arc, is to the line of the latitude, so is the co-altitude of the latitude, to the fun's altitude fought. The determination of such table by this fundamental method is however operose, and Margett's horary tables, which give the fictitious altitudes in any given latitude, would greatly shorten the labour, by giving the results by inspection, which may at the same time be inferred by transfers from the quadrantal arc, similar to those we have already descried. When the horary points are put in for each fictitious hour, when the sun is in the equator, at each tropic, and at the other intermediate places, which may be done thus: when the sun is in the equator, as radius is to the co-altitude of the sun from the meridian, so is the tangent of the latitude, to the tangent of the sun's altitude at the azimuth in the equator; but out of the equator the rule is, as the sine of the latitude, to the sine of the declination, so is the co-altitude of the sun's altitude at the equator at a given azimuth, to the sine of a fourth arc. When the latitude and declination have the same name, as in all azimuths from the prime vertical to the meridian, add this fourth arc to the arc of altitude at the equator; but when the azimuth is above 90°, substract the altitude at the equator from this fourth arc; also when the latitude and declination have unlike names, substract the said fourth arc from the arc of altitude at the equator, for the altitude at the proposed azimuth. The points corresponding to the tabular numbers, thus ascertained, must be inferrd by interposition of lines drawn from A, as before, to the quadrantal arc BC, and these lines uniting those points will be the lines of azimuth for each hour in every day of the year. But to complete the instruments, two lights or vane must be fixed on the meridional line AC, and a small plumb-line, with an adjustable head, must be suspended from the point A of the quadrant.

In addition to the lines already described, Gunter's quadrant has sometimes a square under the angular point A, called a quadrant, as seen in the figure, two sides of which are divided into ten equal parts each, and these again subdivided into others, the use of which is to measure angular distances; and sometimes the large square is subdivided into a number of smaller ones, for the purpose of performing arithmetical proportions by inspection. See Bijou on the Construction and principal Uses of Mathematical Instruments.

It would be tedious to enumerate all the uses of this quadrant, and to exemplify all the problems that it is capable of performing, or rather of illustrating (for great accuracy cannot be expected in the indication of so small an instrument); but we will specify a few of the most useful, which may be varied by reversing the procefses, and altering the data, to a great extent.

PROBLEM I.—To find the Sun's Right Ascension.

Stretch the thread from the point A over the sun's place, as marked in the graduated ecliptic, and the degree cut by it in the quadrantal arc will give the corresponding right ascension.

PROB. II.—To find the Sun's Declination.

Stretch the thread as before, and slide the bead till it rests on the sun's place for the given day, and then turn it to the scale of declination, where the corresponding degree will be seen under the bead.

PROB. III.—To find the Sun's Meridian Altitude on any Day.

Extend the thread over the day of the month given, in its proper scale, till it reaches the quadrantal arc, and the sun's greatest altitude for that day will be indicated thereby.

PROB. IV.—To find the Hour of the Day.

Extend the thread over the day of the month, and, holding it there, slide the bead till it lies on the line of twelve o'clock; then elevate the quadrant so that the polar may pass through the upper right-hand hole and the second, and allow the plummet to rest, and then the bead will indicate the hour, before or after noon, as the case may be. In a similar manner the sun's altitude may be measured by the thread falling on the quadrantal par, when the polar rays pass as above described.

PROB. V.—To find the Sun's Amplitude.

Let the bead be rectified for the given time, and be brought
brought afterwards to the horizon, while the thread remains stretched, and it will indicate the rising or setting amplitude, as the case may be.

Prob. VI.—To find the Ascensional Difference.

Rectify the bead as in the last problem, and bring it to the horizon, in which situation the thread, extended to the quadrant’s arc, will show the ascensional difference in degrees, which converted into time will show how much the fun rises before fix in summer, and after fix in winter, and consequently will give the exact length of the given day.

Prob. VII.—To find the Sun’s Azimuth.

Rectify the bead for the given time, and observe the fun’s altitude as explained in prob. 4. Then extend the thread to the complement of that altitude, and the bead will indicate the azimuth corresponding, and vice versa.

Prob. VIII.—To find the Hour of the Night by a Star.

Put the bead on the thread to the distance that will indicate the star’s declination, and look through the sight for the star till the plummet rests on the plane of the quadrant, and in that situation the bead will show, in the hour lines, the star’s distance in time from the meridian of the place; in the next place subtract the fun’s right ascension in time from that of the star, as given in some catalogue, and to the remainder add the observed distance from twelve o’clock in sidereal time, and the fun will be the hour nearly, or the approximate distance of the fun from noon, which may be corrected by applying the fun’s variation of right ascension since the preceding noon, which in every six hours will be about a minute.

Sutton’s quadrant, and Collins’s sector on a quadrant, are very similar, both in construction and use, to the quadrant we have here described, and the dial on a card, by Ferguson, is nearly related to it, particularly as it has been lately improved by the Rev. W. Pearson.

Of Astronomical Quadrants.—The quadrants which we have hitherto described may be considered as by no means perfect, but as approximating only to an instrument, that is really useful in an observatory for determining the exact place of a heavenly body; hence the quadrant which we propose next to describe, has obtained the name of astronomical, from its superior pretensions to accuracy in the measurement of altitudes taken above the horizon, and therefore merits our more particular attention.

An astronomical quadrant may be either portable or fixed; in the former case it is usually mounted on a tripod, with adjusting screws in the feet, and has a horizontal motion as well as a vertical one, in order that it may take altitudes in any azimuth, or be made to follow the body observed in its apparent path; but in the latter case it is fixed against a steady wall, with its plane in, or very nearly in, the meridian, and is therefore denominated a mural quadrant.

The first astronomical quadrant, of which we have any account left us, is that which Tycho Brahe used; it was the fourth part of a circle placed flat against a stone pier, or quadrangular log of wood, with zero of the arc in the horizontal line, and a pin of wood projecting from the central point throw a shadow on the limb when the fun shone, which shadow was used by way of index; but it is obvious that much accuracy was not to be expected from such an instrument, however well constructed or divided. We might mention here the quadrants of Tycho Brahe and Hevelius, but the former has been noticed under our article Circle, and the latter was destroyed in the conflagration of the owner’s house in Dantizc. In more recent times, astronomical quadrants have been made on accurate principles, and with great care, especially by Graham, Sillen, Bird, Ramden, Cary, and Troughton, several of whose instruments we will now describe, as far as any difference in their construction renders distinct accounts necessary. We will proceed, as we have done on former occasions, chiefly in the order of time, which, generally speaking, will be found to be also in the order of successive improvements.

Mural Quadrant by Graham.—Before we proceed to describe the mural quadrant, contrived and made by Graham, and fixed at the west side of the stone pillar in the middle room at the Royal Observatory at Greenwich, at the expense of king George I., and for the use of that eminent astronomer Dr. Halley, it may be proper to mention that Flamelde, and his assistant Sharp, had previously used an arc of a circle fixed against a stone pier in the meridian, which they had themselves contrived, and which was removed at Flamlede’s death. We must, therefore, consider their instrument as having been the prototype of Graham’s mural quadrant, or arc, as it has been also called sometimes. In fig. 4 of Plate XXIII. of Astronomical Instruments, is given a representation of the mural quadrant of Graham’s construction, which will equally represent that of Bird, constructed after the same model, and which is the fame that both Dr. Smith, and Stone, the editor of Bion’s work, have given in their respective accounts.

The body of this quadrant is composed chiefly of bars of iron united together, as seen in the figure; some, to form the plane of the quadrant, placed flat-ways; and others, to give strength and stability, fixed edge-ways. These bars are all of the same dimensions, namely 2.9 inches wide, and 0.175 thick, and are united together by right-angled short bent bars in various places, both at the interjections made by the sides of the small squares, and at other situations, so that while great firmness is obtained, great weight is avoided. The quadrantial arc is composed of two bars, one of iron, united to the iron frame, and the other of brass, on which the divisions are made, as specified under our article Graduation; this brass bar is pinned fast to the iron one, and being more flemder than the iron, accommodates itsfelf thereto, and, as time has proved, does not alter the shape of the arc, as we have lately been assured by Mr. Troughton. The breadth of the limb is 2.2 inches, the brass limb being more remote than the anterior edge of the iron arc by 1.2 inch, and the surface was planed, or rather sanded, by a tool fixed to a radial bar, that revolved on a vertical axis of motion, placed in the centre of the arc, and resting with its superior end in a fixed beam above the plane of the quadrant, when this plane was lying in a horizontal position, it being impracticable to put so large a body in any ordinary lathe. The original divisions of Graham were inserted on two separate arcs, one graduated into 90° and its subdivisions, and the other divided into 90 parts and its subdivisions, as we have before explained in the article just referred to; but the divisions, being laid down by rough dividing, are not now made use of, but a quadrantial arc of 96, with its subdivisions, put in by Bird in 1753 between the two arcs of Graham, is that which all observations taken by Graham’s quadrant are now referred to, and the readings are transformed into degrees, minutes, and seconds, by an appropriate table. The readings were at first obtained by a double vernier-piece carried by the telescope, that revolves round the centre of the arc, one side of which vernier-piece read with the arc 90°, and the other with the arc of 96 parts, or grand divisions; the degree was subdivided into 12 parts, or 5° spaces, and 10 parts on its vernier equalled 11 out of the said 12 parts, so that
QUADRANT.

A\frac{1}{2} of a degree, or 5\frac{1}{2}, was the length of one of the vernier divisions, and \frac{1}{2} of this, or 30', was the smallest quantity indicated by this vernier; but on the arc of 96 grand divisions there was, as in Bird's arc, 16 equal parts, or subdivisions, in every grand division, and the vernier for this arc had 17 divisions on it, occupying the space of 16 subdivisions in the arc, so that the length of this vernier was \frac{17}{16} of 90° = 59.83 nearly, and one division of it \frac{59.83}{17} = 3.52 nearly.

Hence in the first vernier its number 11 is one left than its equivalent arc contains on the limb of 90°; but in the second, the number 17 is one more than its equivalent arc contains in the arc of 96 parts, on which account the reading of one vernier is in the direction from right to left, but that of the other, on the contrary, from left to right; one meets, and the other overtakes the division strokes of the divided limb; and for the same reason, in the common Hadley's quadrant, or rather octant, sometimes 19 subdivisions, and sometimes 21 on the limb, act against 20 in the vernier, but then the readings are not in the same direction. The telescope is clamped to the arc in any situation by the mechanism for slow motion in the usual way, which probably was first adopted in one of the large quadrants, and its counterpoise beyond the centre of the arc, gives it the advantage of remaining in any position. It has crofs hairs in the focus of the eye-glas. When the lines of the vernier are none of them coincident with any one on the limb of either quadrant arc, the portions lefts what the verniers profefs to indicate were effimated by the eye, by examining the situation of other parts of dividing lines, to the right and left of those nearest to a coincidence; and to a want of a micrometrical nut to the screw of slow motion may be attributed the remark, that has been made, that the readings thus taken, even with fo large radii as 96.85 and 95.8 inches, were not to be depended upon to 10'. That the motion of the telescope might be quite easy, and that the centre of the quadrant might be relieved of its weight, the following contrivance was introduced; \( ab \) represents an iron axis laid across the top of the wall, having two brafs plates fixed perpendicularly to its ends, with notches cut in them for this axis to turn in, which axes points to the centre of the quadrant at right angles to its plane: to that end of it next to the quadrant, \( a \), an iron arm, \( c d \), is fixed, having two brafs plates, \( c e, f s \), almost perpendicular to it; to these are rivetted two brister dips of deal, whose remote ends meet at \( s \), near the eye-piece of the telescope, and are held together by a brafs cap. Through a small plate fixed to one side of a collar, embracing this lower end of the telescope, there pales a screw-pin at \( b \), parallel to the telescope; which pin, being screwed into the cap at the end of the said dips of deal, holds up the telescope against the centre-work, the slips are braced by other crofs dips of the same light wood. The counterpoise \( i \) is supported by the rod \( b h \) at \( b \), the retiring end of the axis \( a h \); and a pair of brafs rollers \( k l \), acting against the limb of the instrument, give freedom to the motion of the telescope thus counterpoised, and complete the construction. The quadrant being thus put together, some strong but small plates of brafs are made fast to its posterior face, and bent so as to fall into as many hold-fails in the wall, into which they are respectivey screwed; but the weight of the whole is supported chiefly by two pins or bolts inserted into the holes \( A \) and \( B \), made in pieces of metal attached to such angular points of the iron bars, as belt support the centre of gravity of the whole: the pin \( A \) is made fast into the wall, but allows a motion round it, and the pin \( B \) fixes the quadrant after its extreme radii are adjusted, one horizontal, and the other vertical: this position was given by means of a plumbe-line of fine silver-wire, that at first was supended as to bisect both the centre of the quadrantal arc and the point 90° on the limb, but which was transferred afterwards to an adjustable point of suspension out of the centre, with a corresponding dot made on the arc of excess of the limb. The plane of the quadrant was made vertical, as compared with the plumbe-line, by the screws of the hold-fails; and the telescope was adjusted parallel to this plane by comparison with a transit telescope viewing together both high and low stars in succession; but the line of collimation of the telescope could not be fixed properly, as it regarded the true horizontal line of the quadrant passing through its zero, without the aid of Graham's sector. This sector was, therefore, so adjusted to a far near the zenith, that it measured the fame zenith distance, with its plane turned to the east, as it did when turned to the west, and had its error ascertained in this way, and afterwards an altitude, taken with the quadrant, was made to correspond with such corrected altitude of a star taken with the rectified sector in reversed positions, which property the mural quadrant does not posses. The method of performing this adjustment for collimation will be understood from our directions hereafter given, when treating of Rutherfurd's portable astronomical Quadrant.

Bird's Mural Quadrant.—After the description we have given of Graham's mural quadrant, we shall have no occasion to dwell long on the structure of Bird's, which was made of brafs entirely, after a similair model, but divided in both its arcs, of 90°, and of 96 grand parts, with more skill than Graham proved himself master of in this part of his labours. Smith and Stone describe Graham's quadrant as fixed to the easf side of the pier at Greenwich, and looking to the south, which was the situation for taking meridional altitudes of the greatest number of stars; but since the year 1753, it has been placed on the west side, looking towards the north, and Bird's then took its original place.

This quadrant, which was procured in the time of Dr. Bradley, was first placed on the west side of the pier, in 1750; and the observations of himself and of Dr. Malkelyne, taken by it since it was placed on the east side, have contributed largely to complete the brafs catalogues of the heavenly bodies, which otherwise must have been very defective. While, however, Mr. Pond, the present altronomer royal, was engaged in making his well-known table of declinations, with one of Troughton's circles, at Woolbury, he found reason to suspect the accuracy of the total arc of this quadrant, from a comparison of his own determinations with those previously made with Bird's quadrant; and a subsequent examination of the arc by Trroughton justifyed his suspicion. With an apparatus expressly contrived for the occasion, this celebrated mathematical instrument-maker measured the total length of the quadrantal arc, and found it too small by \( \frac{1}{7} \), exclusive of another similar error of \( \frac{1}{7} \), occasioned by the wear of the axis of motion; though, on a rigid trial of the intermediate divisions, he did not detect more than one second of error, or rather of inequality, among the neighbouring divisions in any part of the arc. This trial was made in the presence of the present altronomer royal, in the year 1807; and the refult, while it serves to correct past observations, by the addition of \( \frac{1}{10} \) to every successive \( \frac{1}{10} \) of altitude, would have tended tocorrect all future observations by a like addition, had not the large transit-circle, lately made and fixed in the same observatory by Trroughton, superfeded
superfied the use of both the quadrants by its superior accuracy. The quadrantal arc of Graham’s quadrant has not lately undergone a similar trial; but Troughton thinks it probable that the iron instrument has preserved its figure better than the brass one, and that consequently the addition of the brass arc on the face of the iron one has had no undue influence in altering either its temporary or permanent dimensions. At first, the telecope of Bird’s quadrant was not braced; but after a trial, it was found to bend a little by a counterpoise of 80 pounds, and was afterwards braced by frame-work surrounding it, that prevented its yielding. A trial was made by Dr. Bradley of the total arc, in January 1755, after it had remained three years on the well side of the pillar; and though its weight is eight hundred pounds, the error was found to be not more than two seconds. He did the same again in July, in the year 1759, when it had remained six years and a half in its new situation, on the east side of the pillar, and found the arc exactly 90°. These examinations, having been made in the extremes of cold and heat, shew that change of temperature did not affect the total arc; and that, therefore, the 7° diminution of the arc, detected by Troughton, is occasioned by a change of figure in the space of 48 years. The difference of the readings of the two arcs has never yet amounted to 4°, which is a standing proof of the accuracy and skill of Bird as a divider. Near the eye-piece of the telescope is a good micrometer, that not only gives flow motion in taking observations, but measures the number of seconds that the reading lines of the vernier is short of coincidence in any observation; and formerly the quantity indicated by the vernier had these seconds added, to obtain the whole measure; but, by Smeston’s advice, the vernier is now disregarded, and the addendum, obtained by several turns of the micrometer-screw alone, is used to complete the simple reading of the divisions and sub-divisions, or five spaces; in other words, the screw, and not the vernier, subdivides the last five space in the observed arc, and gives what is due to the observation. The adjustments of this instrument, which was made of eight feet radius, on purpose to take the place of Graham’s, are made in all respects as they are made in its predecessor; and the sector, which serves for adjusting Graham’s line of collimation by stars near the zenith, is used for the same purpose in Bird’s quadrant. If any of our readers wish to see the original plan of all the separate parts of Bird’s quadrant, and to read his description of them, we beg leave to refer them to his quarto pamphlet, entitled “The Method of constructing Mural Quadrants,” published by order of the commissioners of the Board of Longitude, in the year 1758. In this pamphlet, however, it is not mentioned that the vernier of the arc of 90° subdivides the space of 5° into ten parts of 30’ each, by having ten divisions thereon, reading with eleven sub-divisions of the limb; but we know that this was the original reading of the vernier.

**Jeremiah Sisson’s Mural Arc.**—Perhaps it would have been more consonant to the order of time, if we had spoken of the younger Sisson, who was Bird’s contemporary, and at one time his employer, next after Graham; but the histories of the two mural quadrants at Greenwich being connected, demanded that these instruments should follow each other in immediate succession. In the year 1768, Jeremiah Sisson, the son of Jonathan, made the large mural arc at the king’s private observatory in Richmond gardens, which extends 45°, or more, beyond a quadrant, and consequently reaches beyond the north pole; which circumstance gives it the advantage of being put in the meridian, by an observation of the pole-star. The divisions of this arc are into degrees and its sub-divisions, but the strokes are not cut very neatly; and the reading, as was the case with Bird’s quadrant at first, is performed partly by a vernier, and partly by a micrometer-screw. We have selected this instrument, as a specimen of Sisson’s construction, principally on account of a power that it possesses, which is very important, but which probably was not contemplated, and consequently not intended by the maker himself: the extension of the divided limb, to several degrees beyond the north pole, affords the means of using this instrument in the manner that Troughton’s large mural circle is now used, at Greenwich Observatory, by the present astronomer royal; namely, to measure the polar distanciae of the stars directly from the true polar point, without any reference to the latitude of the observatory, which method is one of the greatest modern improvements in making astronomical observations. It is much to be desired that this mural arc should be divided again by Troughton, or some other superior divider, and that it have microscopic micrometers applied to it, which may be placed by adjustment over any optional part of the divisions, and at any assumed distance from each other; for though it would not then, as it does not now, possess the valuable property of opposite readings, and of a motion in altitude to reverse the opposite arcs, by reason of its being less than a semicircle, yet being compactly made, and of large radius, it is capable of receiving divisions superior to those on the quadrants which we have just described; and as the situation and structure of the observatory are excellent, the appointment of a regular observer to co-operate with the astronomer royal would be highly conducive to the interests of astronomy. We hope that this hint may be taken up in a quarter where the power exults of realizing our wishes in this respect. Astronomical clocks, and various other auxiliary instruments, are already in the observatory; so that the principal expense of instruments, as well as of an appropriate and elegant building, is already incurred.

**Portable Astronomical Quadrant by Ramden.**—It frequently happens that superior artificers vary the construction of their instruments to suit the views of the purchaser, or the scale on which they are to be constructed. We will select out of the quadrants made by the late ingenious Mr. Ramden, that which he made for Dr. Shepherd for the observatory of Christ-college, Cambridge, and which professor Vince has described at considerable length in his “Treatise on Practical Astronomy.” The figure exhibiting this quadrant is the 5th of Plate XXIII. of Astronomical Instruments, which requires but little explanation. The tripod on which the quadrant is mounted has forew of adjustment to set the item, on which the horizontal motion is performed, perpendicular, which is proved to be so in all directions when the plumb-line bisects both the superior and inferior dots during the whole revolution round a horizontal circle. The visible item is a brass tube, and through it ascends a solid steel vertical axis, which fitting closely at the superior and inferior ends, has not the least shake, and preserves the position once given it for as long as the feet are unmolested. The telescope is of the achromatic construction, and has the usual apparatus for motion, the forew of which is made a micrometer to subdivide the small residue of the angle that the vernier alone will not indicate, when the coincidence is not perfect. The telescope lies on a bar that carries the counterpoise, and in which is the centre of its motion. It has a system of wires in the focus of the eyeglasses, which are adjustable by forew, both upwards and sideways, as well as in a circular direction, so that the adjustments for collimation, and for zero in the altitude circle, may be effected thereby. The point of suspension of the plumbe-line is also adjustable by a proper forew.
apparatus. At the top of the vertical tube, or stem, is a small horizontal circle with a clamping apparatus for slow horizontal motion, by means of which the whole quadrant, with its attached telescope, turns gradually round in azimuth. When observations are made in or near the zenith, the plumb-line falls in the way of the telescope, and is obliged to be removed, on which account the large quadrant made by Ramfden for the duke of Marlborough, and now placed at Blenheim, has the plumb-line suspended at the posterior face of the instrument. This inconvenience is, however, remedied by the addition of a spirit-level suspended from an adjustable horizontal brass rod, under the uppermost radial bar of the quadrant, and this level not only supplies the place of the plumb-line when taken off, but at all times serves as a check on its adjustment, and, when furnished with a graduated scale, may very well be made its substitute.

The construction of Ramfden's portable quadrant was probably borrowed from Bird's, as well as his method of dividing the larger instruments that exceeded the reach of his dividing engine; but the instrument before us has no other horizontal or azimuth circle, except what is used plain, for the purpose of giving slow motion. Neither is there a second horizontal telescope fixed permanently in that situation by which the telescope of observation may have its collimation determined, and the zero of its vernier adjusted.

The vernier of this quadrant reads with two sets of divisions, like that of the mural quadrant by Bird, but the radius being small, the sub-divisions are made into four parts each; the inner arc is divided into 90°, and the sub-divisions into 15° each, but the outer one into 96 parts, or grand divisions, and these again each into four parts, or sub-divisions; and those two arcs operate as a check on each other. The micrometer sub-divides the 15° into 3°; but it is necessary to convert the reading of the arc of 96 grand divisions into a corresponding quantity, expressed in degrees, minutes, and seconds, which may be done by direct proportion, or, which is more feasible, by a table that we have subjoined, calculated for this purpose. The readings of the arc of 96 are put down with titles divisions, sub-divisions, and vernier, where 16 (and sometimes 32) on the vernier are equal to one sub-division, and four sub-divisions to one division; for example, suppose the reading to be thus, 21 div. 2 sub. 11 ver. we shall have from the table

</table>

When, however, the coincidence of the vernier is not perfect, the quantity brought up by the micrometer-screw must be added as a fractional portion of 52.°8', which is the value of one step of the vernier, when 16 is the number of steps, but if 32 are inferred, then 26'.4 would be the value of one step forwards from zero.

A Table for the Reduction of the Grand Divisions, Sub-divisions, and Vernier, of the Arc of 96, into Degrees, Minutes, and Seconds.

Adjustments—
Adjustments.—1. To adjust the axis of the pendial vertical.—This adjustment may be performed either by the plumb-line or by the level, both of which methods we will explain in succession. We have already said that when the wire of the plumb-line will continue to bisect both the upper and lower dot, while the instrument is turned quite round in azimuth, its axis is vertical in all directions, but this could not be effected unless the plumb-line passing through the two dots were also parallel to the axis; this adjustment, therefore, is made partly by the screws at the feet of the tripod, and partly by the screw that moves the piece bearing the upper dot in a lateral direction. In the first place then turn the quadrant in azimuth till its plane, or, which is the same thing, the telescope lies parallel to a line joining any two of the three feet, and turn one of these two screws till the wire bisects the lower dot, and with the proper screw bring the upper dot to the same wire; then reverse the telescope by turning 180° in azimuth, and if both dots are again bisected, the axis is vertical in the direction that the telescope has pointed; in the next place turn the telescope the space of a quadrant till it points in the same direction as the third foot of the tripod, and make the wire bisect the lower dot by the screw of this foot, and it will be found to bisect the upper dot also, if the first adjustment of the dot was properly made, but if not, repeat the operation till both dots are bisected in all the reverberated situations of the telescope, and then the axis will be vertical in every direction.

In making this adjustment by the level alone, the processes must be thus; first, the level must be made parallel to the rod on which it hangs, and, secondly, this rod must be put perfectly horizontal, and the level will then be horizontal also, with the bubble in the middle. In order to make the level parallel to the rod, place it parallel to a line joining two of the feet screws, and bring the bubble to the middle by one of the feet screws in question; then take off and reverse the position of the level, and if the bubble is found in the middle now, the parallelism is perfect, if not, one half of the error must be rectified by the foot screw, and the other half by the adjusting screws at the end of the rod, by releasing one and screwing up the other. A repetition or two of this process will make the bubble stand in the middle in both of the reverberated situations. In the next place, with the level thus parallel to the rod of suspension, turn the quadrant round its axis an entire semicircle as nearly as can be estimated, and if the bubble will now rest in the middle, the rod is level, and being at right angles with the axis of the quadrant's motion, proves that this axis is vertical in every direction; but if the bubble is found to run to one end of the tube, bring it one half way back by the rod's adjusting screws, releasing one and fixing the other, as the case may be, and the other half by the proper foot-screw. A repetition of this process will soon settle the bubble in the middle during a whole revolution in azimuth, and then the adjustment of the axis is perfect, as well as of the rod and level.

2. The second adjustment is that by which the line of collimation of the telescope is made parallel to the horizontal line that passes from the centre of the quadrant to zero on the limb, or quadrant arc, at the same time that zero on the vernier coincides with zero on the limb. This important adjustment may be made in several ways, some of which are tedious and otherwise objectionable; but we will confine ourselves to two which apply, one to the vertical, and the other to the horizontal line of the quadrant, which two methods, when duly effected, will not only check each other, but detect the error of the total arc, if there is any, at the same time; which is an acquisition of the utmost importance. First then, to adjust by the vertical line, let the axis of the quadrant be first made truly perpendicular in all directions by the adjustment we have already described, and fix on a star within a few degrees of the zenith, when exactly on the meridian, and measure its altitude by the cross-wire in the field of view in the usual way, and note down the result; do the same on a successive night soon after, if possible on an evening of similar temperature, with the quadrant turned half round in azimuth, and note again the result; if these readings prove to be at equal distances from the point 90°, one on the quadrant arc, and the other on the arc of excess beyond 90°, the horizontal wire is truly placed in the eye-piece, but if not, half of the difference of the readings must be corrected by the proper screw for raising or lowering the said wire. This may be done by directing the telescope to a distant mark till the cross-wire bisects it, then by moving the screw of flow motion of the vernier the half quantity required, and by bringing back (up or down) the cross-wire thus displaced to its original mark again. This operation repeated will place the cross-wire in such situation, that zero on the vernier will be in its proper place with respect to the point 90°; or the half difference thus ascertained may remain, without altering the cross-wire, as an error of adjustment to be constantly applied with the sign + or —, as the case may be, in all subsequent observations. Again, to adjust by the horizontal line passing through zero of the quadrantal arc, it will be necessary to have a second telescope turning on pivots in adjustable Y's attached to the back of the quadrant, on the same axis with the said horizontal line of the quadrant. This telescope may be called the adjusting telescope, and may be also used to catch a distant mark, before and after an altitude is taken, in order to detect any deviation in the position of the vertical axis, that may happen during the operation of measuring. Let the adjusting telescope bisect a fine distant mark with its cross-wire, and turn the tube of the telescope round one half way on its pivots, as it lies in a horizontal position, and if the wire now bisects the same mark it is truly fixed, if not, look out for a new mark a little higher or lower, as the case may be, and make it cut that in the reverberated positions of the cross-wire, by means of the proper screw for this purpose; now this adjusting telescope will be adjusted for collimation; in the next place, put zero on the vernier to zero on the limb, and direct the telescope of observation to the same distant mark, by which the adjusting telescope had its wire adjusted, and let this mark be bisected by both telescopes, the level and plumb-line at the same time shewing that the vertical axis is perpendicular; now turn the quadrant half round in azimuth, and reverse the adjusting telescope so as to view the same distant mark again, and if it is found to bisect it as before, the horizontal line of the quadrant is right, and also the quadrantal arc without error, supposing the telescope of observation to have its adjustment for collimation as fixed by the point 90°, above described; but if this adjustment of the point zero on the limb be first made, half the apparent error must be rectified by the screw at the eye-piece, by means of reverberated positions and new marks; and then afterwards the adjustment by a star near the zenith will detect the error of the whole arc. If, however, no error in the total arc exists, then the adjustment for collimation may be made either from the horizontal or from the vertical measurement, as may be most convenient; one of which is more practica by day, and the other by night. When this delicate and very essential adjustment is finally settled, the object glaft of the telescope should not be disturbed, and therefore it would be advisable to have its interior surface well cleaned previously.

It was taken for granted that the cross-wire was perfectly

horizontal
horizontal during the time the preceding adjustment was made, or, which is the same thing, that the parallel vertical wires were perpendicular to the horizon. This is proved by simply immersing the direct telescope to a fine small distant mark, and make the adjustment for vision, if necessary; then if one of the vertical wires will continue to bisect the said mark through the whole field of view while the telescope is elevated or depressed, the wires are right, but if not, they must be made so by the proper screws for that purpose, near the focus of the eye-glasses. This preparation ought to precede the last adjustment, and when once made, seldom requires altering, except in case of accidental injury.

It has also been assumed in the preceding adjustment, that the maker of the instrument placed the plane of the quadrant parallel to the axis of its motion, and also the line of collimation of the telescope parallel to the said plane. The former may be known to be true thus; if, when the plumb-line is adjusted, at its centre of suspension, just to cleape touching the limb, (which should always be the case,) the quadrant's motion in azimuth will not alter it in this respect, the plane is truly fixed; but if not, the wires, that fix the quadrant to its axis, must be relaid to for the alteration, which is best done by the maker. When there is no plumb-line, a small spirit-level, fixed at right angles to the plane of the quadrant, will answer the same purpose; for the realing of the bubble during the quadrant's revolution in azimuth, will be a proof that the plane to which it is at right angles is vertical. With respect to the parallel position of the telescope, as this is guided by the vernier sliding on the limb, it is the business of the maker to adjust properly, which he will best do by a comparison with a good transit instrument of the pathages of a high and of a low star in each of the two instruments; but a small deviation of the telescope with respect to parallelism, though to be avoided, will not sensibly affect the measurement of altitudes, which is the sole business of this instrument. If, however, this deviation is considerable, the eye-end of the telescope must be set nearer to or farther from the limb, as the case may be, by the maker himself. We have been the more minute in describing these adjustments, not only because they are indispensably necessary in making good obervations, but because they will apply, one or other of them, by means of the plumb-line, or of the spirit-level, to all other astronomical quadrants that have a motion in azimuth.

We have before us the drawing of a large and beautiful quadrant made by Mr. Cary, for Leopold, the late grand duke of Tuscany, with two telesopes and a graduated azimuth circle, but the description we have given of Ramfic'd's instrument will equally apply to his, except as to the dimensions.

Portable Astronomical Quadrant by Troughton.—Though we have described Ramfic'd's portable astronomical quadrant with much minuteness, and have detailed the most useful methods of making such adjustments as will apply to the other portable quadrants that have a motion in azimuth, yet we should do violence to our own feelings, as well as to the integrity of an existing article of the firm, if we withheld from the public eye the great improvements that he has made in this instrument since the death of Ramfic'd. Fig. 6, of the same plate that contains Ramfic'd's instrument, is a reduced perspective view of the improved astronomical quadrant of Troughton, which was made by him and sent to Bilboa in Spain, about the time that astronomical circles began to be constructed. It has been ascertained, under our article Circles, that this instrument, as constructed by Troughton, (and we may now add, by Thomas Jones, who has learnt his mode of dividing,) is greatly superior to any quadrant that can be made, on account of properties which the circle exclusively possesse; but so far as a quadrant's accuracy can be depended on, Troughton's improved construction is to be preferred to all others. And, indeed, when we consider that simplicity, flatness of production, and permanence of the adjustments once made in this instrument, are properties which it peculiarly possesse, along with comparative cheapness, it is probable that there will always be purchasers, when such an instrument is on sale, provided the improver will content to make such instrument with limited powers, when he can have rapid sale for those which he now constructs, with all the advantages that the circle affords.

The radius of this quadrant is three feet, and the body is made double, that is, of two quadrantal frames united into one, by small pillars holding their planes parallel, and ensuring the two properties, not often united in other men's instruments, of lightness and strength at the same time. The tripod, on which the quadrant is supported, is a frame of mahogany, braced in different directions, so as to resist any accidental pressure, when the quadrant is put in motion, or the telescope used. The three feet-screws are furnished with each a Hook's joint and handle, so that the observer may make an adjustment with any of these screws without flopping, and consequently without withdrawing his attention from the plumb-line apparatus, or spirit-level, that indicate the quantity of adjustment that may be necessary from any individual screw. About the middle of this pedestal, or frame-work of the tripod, is a three-armed horizontal bracing piece, on which the limb of the quadrant rests; and this limb is kept vertical by a socket of brass made fast to the centre of the table, that furnishes the pedestal, in which socket the vertical axis turns both steadly and freely, while it rests on the three-armed bracing piece below. The azimuth or horizontal circle is centered on this axis, but so as to admit of a motion round it of about two degrees, for the purpose of putting the zero of the quadrant right when the telescope is in the plane of the meridian. This small motion is produced by the tangent screw seen in front, and the other tangent screw regulates the flow motion of the telescope and vernier, by taking hold of the solid vernier plate, that reads at opposite points, and that may be clamped, when in use, to the azimuth circle, which is also a solid circular plate of brass, subdivided into 10° spaces, and reading by the verniers alone to 10'.

The vernier or index-plate is of considerable depth, and hollow, terminating with a chamfered edge below, and contains in it a triangular frame not seen, foldered to it, and opposed, for the sake of strength, by another similar frame seen above its plane. From the frame within the hollow index-plate arise three small pillars, which support the upper triangular frame at the three corners, and passing through it receive so many milled nuts on their tapped ends, by which means the whole are compactly united. These milled nuts are useful for adjusting the plane of the quadrant parallel to the vertical axis of the quadrant's motion in azimuth; and it is here where the quadrant is to be separated from the hand for cloche package. Upon the upper triangular frame is foldered a short but strong conical tube, that supports the long column that terminates with a supplemental cone. From nearly the lower extremity of this long column a couple of braces ascend about twenty inches to the upper part of the body of the quadrant, and, by being made fast to it, complete the flatness of the structure in an admirable manner. The telescope, which is about forty-two inches long, and achromatic, as well as furnished with an adjustable fynem of Spider's threads, tapers from the object-glasses down-
downwards, to prevent any inclination to bending by its weight, and has an axis of motion of four inches and a half long, that passes through the thick pillar, that connects the two quadrant portions of the double frame at the exact centre of motion, and of the divided arc. The counterpoise is applied at the redundant end of the telescope, and the vernier borne by its end, near the eye-piece, divides the 5'= spaces of the vertical arc into 5" while a micrometrical microscope, attached to the metal of the telescope, subdivides this half quantity into single seconds. A nicely ground spirit-level hangs on the horizontal bar, with its proper adjustment apparatus, which alone will ascertain the position of the quadrant to a second; but, as this were not sufficient, a plumb-line is made to descend, free from dust, or agitation by the wind, from an adjustable point of suspension through the hollow column, where there is little or no disturbance from a motion in azimuth, and ensures the position still more certainly. The water vessel in which the plummet is immersed, to prevent vibration, is contained in the hollow short cone before described, as containing a triangular frame within it, and the situation of the wire is examined in two directions, at right angles to each other, by microscopes looking across the bore of the column, at a convenient height for the observer to see without a change of position of his body, when he has been just observing at the telescope. The mark used for each wire to bestick is a luminous disc, known by the name of Ramdjen's glass, from its being only the image of a luminous point without substance, occasioned by a contracted aperture of a tube, fixed at the remote side of the column into which light enters, and by which it is directed without parallax. Besides the appendages, there is a secondary or adjusting telescope, such as the elder Sillon made for his spirit-level, and such as we have already described, as furnishing the means of adjusting the horizontal line of a quadrant that moves in azimuth, and of ascertaining the error of the whole quadrantal arc, by comparison with the adjustment by a star near the zenith. (See Portable Astronomical Quadrant by Ramdjen, before described.) Lastly, the radial bars that bear the quadrantal arc, taper downwards from the centre, thereby giving strength to the part most liable to alter its figure by weight, as it is supposed Bird's mural quadrant has done in a small degree for want of such precaution. This quadrant has an arc of excess at each end, and is capable of all the adjustments we have above described in an exquisite degree.

Of Nautical Quadrants, measuring by Reflection.

Sir Isaac Newton's reflecting Quadrant.—A manuscript account of a quadrant, measuring altitudes and distances by reflection, of the hand-writing of Sir Isaac Newton, was found among the papers of Dr. Halley after his death, which quadrant, according to Stone, was actually made in the year 1672, when Dr. Halley was preparing to go to the South seas, to make an addition to his catalogue of fixed stars; but the manuscript account was not produced, or even mentioned, when Halley's instrument was shewn to the Royal society, nor was made known till the year 1742. (See Phil. Trans. N° 465.) Hence some doubt has been entertained whether Sir Isaac Newton or Halley was the first inventor of the reflecting quadrant. The most probable inference is, that each invented his own, seeing that though the principle is the same in both constructions, yet the mode of applying it is different, as will be seen from a comparison of the figures, and from our description of each in succession. Sir Isaac Newton's quadrant was preferred for several years at the house of Mr. Heath, who was a mathematical instrument maker in the Strand, London, and it is probably in existence at this time. Dr. Hooke is also said, by Dr. Pratt, to have invented a quadrant that was, or might be, used at sea with one reflection only; and, indeed, he is allerted to have been the first man who proposed the use of a mirror in a nautical instrument. See Circle.

Sir Isaac Newton's quadrant, represented by fig. 7. of Plate I. of Astronomical Instruments, consists of an entire sectorial plate of brass, P Q R S, to the plane of which the telescope A B is fixed and lies parallel, and an index, which is moveable about an axis of motion at A. The limb D Q was accurately divided into half degrees, and, as is said, half minutes, on a scale of four feet radius, and was subdivided by a diagonal scale into 4th of a minute. The principle on which this semi-division is founded is this; viz.

If a fixed ray of light be reflected at a plane reflector, and if the reflector be made to revolve about an axis perpendicular to the plane passing through the incident and reflected rays, which may be called the plane of reflection, the angular velocity of the reflected ray will be double to the angular velocity of the reflector.” See Vince's Practical Astronomy, p. 7, &c.

Hence one small mirror, G, is made fast to the plane of the sectorial plate, and perpendicular thereto, but inclined in an angle of 45° to the axis, or length of the telescope, and in such a way, as to cover one half of the aperture, while another similar mirror is borne by the index, in such a position, that when the index is at zero, both the mirrors are not only perpendicular to the plane of the quadrant, or rather octant, but are parallel to each other. Now, according to the principle that we have just mentioned, when the index is moved forward, a ray of light from any fixed luminous body, when caught by the index mirror, will be reflected on the fixed mirror, and an eye directed through the fixed telescope towards the fixed body, will see it divide into two bodies; the first of which is the index begins to move; that is, the body itself will be seen stationary through one half of the telescope's aperture, and its image will be seen in the other half in motion, and this motion has double the velocity that the index has, which bears the revolving reflector; and on this account it is, that the divisions for half degrees and half minutes, are read as whole degrees and whole minutes, as well as the 4th read as 4th by the diagonal scale. From this short explanation of the principle and structure of Sir Isaac Newton's reflecting quadrant, it is easy to perceive that the construction is derived immediately from the principle in the simile, though in practice not the best manner; for the instrument itself illustrates the principle in the most obvious way; but, from its magnitude and mode of being used, it is very inconvenient to be supported without a stand, which on board a ship is inadmissible.

Perhaps it might be on this account that Dr. Halley did not pay more attention to it than he appears to have done, according to the information that we at this distance of time possess. However, it is evident, that the instrument before us is capable of measuring either vertical, horizontal, or oblique angles, in the way it professes.

Cole's Quadrant by Single Reflection.—Fig. 2. of Plate XXIII. of Astronomical Instruments, is the figure of an instrument, which, like Dr. Hooke's contrivance, measured altitudes by single reflection, as we conceive, the drawing having fallen into our hands without the description. An arc composed of an entire quadrant, and an index with a single mirror fixed to it at its centre of motion, constitute its leading features, while a light-vane, at the remote end of the prolonged index, instead of a telescope, has a plane hole, through which the sun is viewed after reflection from the index-glass, his rays having first passed through a coloured glass.
This construction, with the addition of the lens of Isaac Newton's second mirror, would constitute a union of two instruments, that would greatly resemble the combination adopted by Mr. Hadley, which follows next in our list of quadrants; but which may not have been copied from such union; for Cole has got the vernier scale, which is preferable to the diagonal one adopted by Hadley, and therefore probably he followed Hadley, though the quadrant before us, has not recommended itself to general use, as being an improvement.

HADLEY'S QUADRANT.-As we cannot help considering Hadley's quadrant, or more properly octant, as a near relative at least to his friend Isaac Newton's, we will describe it next in order, while the principle of its construction is fresh in the reader's memory. The circumstance of Mr. Hadley's being president of the Royal Society was favourable to the early notice of his instrument; and the interest that the British nation took, and must ever take, from its nautical situation, in nautical improvements, contributed to its early adoption, at a time when such an instrument was greatly wanted.

Mr. Hadley, we learn, tried various modifications in the construction, but that which has been approved from long usage is the one we shall select for description. Fig. 1. in Plate XXIII. of Astronomical Instruments, is the representation of Hadley's octant, as it is now constructed with a vernier, which it had not at first, and which is preferable, to the diagonal divisions at first applied by Hadley, as well as by Sir Isaac Newton. For the sake of lightness, united with strength, the frame of the instrument, when made of any of the hard woods, is put together usually as is represented in the figure, but when made all in brass, and particularly when the limb is extended to 120°, the scale is called a sextant, in which case it is a file, and which modern makers make it under; that is, have two separate light images, united by short pillars, floating at right angles to their planes, which thus become parallel. This construction, we believe, was introduced by Mr. Troughton, and allows a more steady motion to all the moveable and adjustable parts, by lengthening their axes of motion, which penetrate across both parts of the double frame, and by that contrivance have longer bearings. But we are now propelling to describe a quadrant of Hadley's own construction. A B C is a frame of some hard wood, such as ebony, which may be of any convenient radius, from eighteen inches downwards to three, or less, if required for the pocket, and A D is the index bearing the vernier at D, together with the universal clamping apparatus for flow motion, in making the contact in any observation. This apparatus, together with the powers of the vernier, and mode of using it, have been explained under our article: Circle, (see also Vernier,) and therefore may be referred to by the reader unequainted with their use. When the radius is very small, the vernier subdivides half degrees, and has thirty divisions on it, but has twenty or fifteen, accordingly as the degree of the limb is subdivided into thirds or fourths of a degree. The peculiar excellence of this instrument, either in the form of an octant or sextant, is, that all sorts of angles can be measured with it, and a ship, even while the ship is tossed by the waves; and also, that it requires no other auxiliary means, than the natural horizon, which at sea is always, or mostly present, when a heavenly body can be seen. The plumb-line and spirit-level are equally dispensed with; to which may be added, that, if any accidental injury be received, a circumstance not improbable in the hands of sailors, the adjustments are so simple, that, generally speaking, the derangements may be easily rectified. In the best instruments, a small telescope is screwed into the right-vane, which not only prevents parallax, by limiting the line of sight between two parallel wires, but affords the light greatly in obtaining exact contacts. There is usually an arc of excess at each end of the limb, one of which is useful in adjusting the index-error by the sun or moon, and the other is serviceable when angular distances are measured beyond a quadrantal arc; indeed it would be well if the arc were always extended to measure 120°, or more, for then a sextant would be competent to measure all parts of angles that the mariner can require, to find his latitude, time, and longitude.

When the octant has not the tangent screw of flow motion for adjusting the contact, the index is nicely moved by hand, and then fixed by a screw behind it for this purpose, and in either case the examination and noting down of the altitude, or horizontal angle taken, may be read at any time, for hours afterwards, which is another important advantage that this instrument possesses in common with the sextant; for where more observers than two are not present, one observer may thus manage to take both an altitude and a distance in a lunar observation with two separate instruments in quick succession, while another observer is taking the altitude of the second object; or with the help of Margret's horary tables, the second altitude may be had by inspection, when the hour, latitude, and declination of the body are known, in which case one observer can take a lunar observation with tolerable accuracy. The limb of the instrument is best of metal, such as brass, silver, or platinum, when made and divided in the best way by a superior dividing engine, such as Troughton's; but in ordinary instruments a piece of ivory is frequently let into the wood, and sometimes the divisions are made even on the wood itself, which is liable to be affected by moisture. The index is most frequently entirely of brass, and wider as it ascend to the centre of motion, to prevent lateral bending, which would destroy the accuracy of the readings. When an observation is made by the larger fort, the right hand should be applied to the lower extremity of the index to give it steady motion, while the left holds the lower end of the remote radial bar; and the plane of the instrument must be kept in the line that joins the two objects, of one of which the horizon is one, when an altitude is taken, and then the instrument is held vertical. In bringing down the image of an object to the horizon by a fixed observation, the body of the observer must gradually incline towards the horizon, and a little vibrating motion will suffice in determining the exact plane of contact; but in taking a horizontal angle, the observer will handle the instrument as best suits his convenience. The mirror at A is placed over the centre of motion of the index, in a direction pointing to zero on the vernier, and perpendicular to the flat face of the index; this index-glass, being completely silvered, reflects the light it receives directly at right angles on the glass E, when the zero of the vernier is at the zero of the limb; but as the limb proceeds forwards, this angle alters, and, as we have said, is double of the measure of the real angle to be measured and indicated. This glass E is also fixed perpendicular, and has screws of adjustment for perpendicularity above its socket of brass, and a tail-piece with a fixing-screw behind the frame, for fixing the parallel limb; the want of which is called the index-error: one half only of this glass, which is called the for-horizon glass, is silvered, and the other half remains unsilvered, in order that both the direct rays transmitted through the unsilvered part, and the reflected rays coming from the silvered part, may meet at the eye, on which accounts the middle of this glass, where the line of separation crosses, is the part to be viewed
viewed in making a contact, otherwise both the image of one object, and the substance of the other, could not be seen at the same instant. F is the sight-vane, with two holes, usually an upper and a lower, inserted into the first radial bar of the frame, so that the holes are at the same distance from the plane of the instrument as the line of separation is in the half-fibered glass E, to prevent parallelism of the reflected rays, and in the belt instruments this vane, with its telescope, has an adjustable motion to and from the plane, in order that more or less light may fall on either of the bodies observed, which is not only useful, but necessary, in taking a lunar distance; for by this adjustment the image of one body may be made as luminous as the real body of the other, by increasing the light of one, while it decreases that of the other; that is, by making more of the filtered, or the unfiltered part of glases E, fall before the object-glass of the small telescope, when this adjustment is necessary. It may be necessary to observe here, that every filtered glase of sensible thickness has two reflections, one on the anterior, and the other, which is the principal one, on the posterior or filtered face, and in many cases errors may be occasioned by these double reflections; to remedy which, Dr. Mackay proposes, that the filtered portion of the posterior face should be ground rough and painted black, taking care that the grinding be so performed, that the line of separation between the polished and unpolished parts be parallel to the plane of the object.

In the back horizon-glass, which is that seen with its sight-vane at G, with adjustments similar to those of the fore horizon-glass at E, the whole posterior face is fibered, except a slit, that divides it in a line parallel to the plane of the frame, through which slit the body is observed in a back observation. But when the fun is the body observed, his light is generally too intense for the eye to bear, particularly when the small telescope is used; to render the rays tolerable to the eye, a colored glase, or glases, must be interposed, and a blank tube instead of a telescope be used, by which means the fun may be viewed without doing injury to the eye; and usually a system of colored glases are flided into a square hole, as at H, and a joint in each allows them, or any one of them, to be brought forwards into the situation where the direct rays must pass to the eye. The same remedy is also sometimes applied at the eye-piece of the blank tube, when the fun alone is observed. The plane of the back horizon-glass is placed not only parallel to the plane of the frame, but at right angles to the plane of the fore horizon-glass, in order that the fame readings may apply in both kinds of observation, and this object was effected by the maker by the simple rectangular position of the two horizon glases to each other, and by reverting the position of the body in making a back observation; for as the inclination of the index-glasses to the fore horizon-glass gives double the angle directly measured, so twice the complement of this inclination to the back horizon-glass gives the same quantity, and on the same part of the graduated limb, when measured in a reversed position.

Adjustments.—The adjustments of every instrument are of the utmost importance to the accuracy of observations taken thereby, but they are particularly so in the instrument before us, because a small deviation from parallelism in the fore horizon-glass, or from perpendicularity in the back horizon-glass, as compared with the index-glass, (with the vernier at zero of the limb,) will double the error occasioned by it in the quiescent situation, as soon as motion is given to the index-glass. 1. The first adjustment is, to set the index-glass perpendicular to the plane of the instrument: this is done by first sliding the index to about 45° or 45° of the limb, while the octant is held with its plane nearly parallel to the horizon, then a glance into the index-glasses will shew, whether the sharp edge of the limb seen by reflection, is an exact and straight continuation of the same edge of the limb seen by direct vision, and if this is not the case, it must be made so by the screws that adjust the bed of the mirror; and in all cases where two screws are to be used, one must be released as much as the other is screwed inwards. Dr. Mackay proposes to place two small pieces of metal as adjusting tools, with each a horizontal line drawn on it, at equal heights from the plane of the limb, at some distance from each other, so that the horizontal line of one may be a continuation of the horizontal line of the other, when one is viewed by reflection, and the other by direct vision, but the sharp edge of the inner part of the limb will answer all ordinary purposes. 2. The second adjustment is, to set the fore horizon-glass perpendicular to the plane of the instrument: this is done by first fixing the zero of the vernier at zero on the limb, and while the plane of the frame is held parallel to the horizon, by applying the eye to the lower hole of its sight-vane; then if the horizon, or any distant horizontal line, appear to be a straight line, the glase is placed perpendicular already; but if the parts seen by reflection and by direct vision do not constitute a straight line, they must be made to do so by the screws at the bed of the glases, one or other of which must be screwed in, as the fracture of the line demands, that is, if the line seen by reflection appear above that seen by direct vision, that screw must be urged inwards which is on the farther glase, and vice versa, until the fractured line be straight. 3. The third adjustment is, to rectify the index-error of the fore horizon-glas, or to place it parallel to the index-glass, when the zero of the vernier is placed at zero on the limb. To do this properly, a bright distant object must be chosen, such as the sun, moon, or star, and while the zenos coincide, look through the vane, or telescope, and observe if the body and its image coincide; that is, if the image is invisible: in this case, the fore horizon-glass is parallel to the index-glass, or is truly adjusted; but if not, release the tail-piece or lever behind this horizon-glass, and with the thumb-piece give it a small motion, till the body and its image coincide, in which situation it must be fixed by the fixing nut before released. Sometimes the act of screwing will displace in some degree the tail-piece, and thereby again occasion a sensible index-error. When this cannot be completely avoided, the error must be ascertained and allowed for with its sign or — in every subsequent observation, while it remains unaltered. This error may be ascertained by measuring the diameter of the fixed forwards on the limb, and then backwards on the arc of excess, and one half of the difference of the measures will be the index-error + or —, as the case may be. 4. The fourth adjustment is, to set the back horizon-glass perpendicular to the plane of the instrument: this adjustment is similar to the second, and may be performed by the directions there given, supposing them to be for the back horizon-glasses and its vane, instead of the fore horizon-glasses. 5. The fifth and last adjustment is, to set the back horizon-glass perpendicular to the plane of the index-glasses produced, the zero of the vernier being placed at zero on the limb: this adjustment at sea is performed thus: let the vernier be put as much to the right of zero, as is equal to twice the dip of the horizon, in the situation where the observer stands, then hold the quadrant in a vertical position, and apply the eye to the back-horizon vane: now, if the horizon seen by reflection happen to coincide with that seen by direct vision, the glases is already right; but if not, the lever or tail-piece behind the frame at this place must be released by the proper fixing screw.
QUADRANT.

ser, and turned slowly by the thumb-ferow or nut, till this coincidence is perfect, and then the lever must be made fast again; the reflected horizon will be inverted when viewed in the manner above described. When the instrument is used in a back observation on the land, which is not likely to happen often, the adjuftment will require some artificial aid: by Dollond's method, an index is applied to the back horizon-glafs, by which it may be put parallel to the fore horizon-glafs, by the third adjuftment applied thereto, and then, by a graduated arc of 90°, inferted on purpose, the index of the back horizon-glafs is let perpendicular to its former situation, and consequently is made perpendicular to the plane of the fore horizon-glafs. By Mr. Blair's method, the under edge of the index-glafs is ground and polished, so as to be at right angles to the plane of the glafs, and hence the back horizon-glafs is adjusted, by making the direct and reflected horizons agree, while the vernierstands at zero on the limb, exactly as is done in the third adjuftment. But we are to suppose the instrument not furnished with either of the above named auxiliary means; when this is the cafe, a long level space must be chosen in some common or park, where three flaves can be put up in the fame straight line exactly, and at an interval from each other of not lefs than 500 yards, but if 600 or 700 the better; then, the vernier being truly placed at zero, let the plane of the octant be held horizontally with its back horizon-glafs exactly on the top of the middle staff, and let one of the rods be viewed directly through the back fight-vane, then if the other rod, seen by reflection, coincide with it, the position of the back horizon-glafs is true, but if not, it must be made fo, by the tail-piece behind, as before directed; if in fixing the tail-piece a derangement should take place, which cannot be exactly done away by a second or third trial, then the index-error for the back observation must be ascertained.

This error may be obtained by reverfed observations by two methods; thus, let the coincidence of the two extreme flaves be made from the middle staff as just directed, by a motion of the vernier, instead of the tail-piece of the back horizon-glafs, and read the quantity moved forwards or backwards; then turn the downward face of the frame upwards, and repeat the operation, and read again; now, if these two readings are found to be one on the limb, and the other on the arc of excess, half of their difference will be the error sought, + or — ; but if they both are read on the fame side of zero, half their sum, + or —, will be the error; when they are both read on the limb, or if the greater quantity be read on the limb, when the less is on the arc of excess, the sign will be —, and vice verâ. By the second method, instead of reverting the plane of the instrument, let the observer reverfe his position, making the right-hand staff to be the left-hand one, and vice verâ, and then let him repeat his first observation, with the fame face of his instrument up that he had in that, and the fame result will follow, that was obtained by reverting the plane of the instrument. These two modes of obtaining the error in question, by reverfed observations, may be made to check each other, and will then give an average of the two results, for the error to be applied to each subsequent observation, taken with the back horizon-glafs in its last determined position.

Examination of the Instrument.—These several adjuftments being fulfilled, the observer might proceed to make his observations, provided he could rely on the skill and credit of the maker of his instrument; but if not, he would act prudently to examine the materials of which it is composed, before he relies on its performance, and also to put to some test the accuracy of the divisons on the vernier and limb, as well as the care that has been taken in selecting glases of uniform thicknefs, and of good polish. The exactnefs of the total arc may be ascertained from comparison with measurements taken with a circle, or some well-known superior instrument; or by careful trigonometrical measurement on some level and extensive ground, where the sides of the triangle can be accurately measured, for which purpose Troughton's new chain of five-feet links is admirably calculated; but the intermediate divisons may be examined by the vernier itself, by stepping the arc with it; and if all parts of the arc are found alike divided, when examined by the coincidence of the extreme strokes of the vernier, the intermediate strokes of the vernier itself may ladily be examined by the strokes on the limb taken in various places.

Dr. MacKay recommends a table of corrections to be made, in case of errors being detected in the dividing, but we should rather recommend new divisons from a good engine, the inferting of which can now be performed at a trifling expense. When the planes of the mirrors are examined, try if a candle reflected appears in two images; if it does, the two faces of the glafs are not parallel, and consequently the glafs is not fit for its purpose.

To try whether the surfaces of the mirrors are perfect, bring two distinct different objects into good contact, and let them be seen at the upper edge of the silvered part; then move the instrument in its own plane, and move the image and body along the line of separation or edge of the silvered part, and if the coincidence is not disturbed the plane is perfect, but not otherwise. Also, when an observation is taken of the sun, and the vernier has been fixed by the fixing ferow, read the altitude, as the dark glafs, or glases, may have been used; then remove them from the pocket that holds them, and reverfe their planes, by putting their remote faces nearrell; and if, after this change, the fame altitude is given, the planes are parallel, otherwise half the difference must be applied, in all such cases, as an error of the coloured glases. This examination is best made exactly at noon, when the sun's altitude is not sensibly changed during the examination; unless a good chronometer or regulator, duly regulated, and put to exact time, be at hand; for then the successive examinations may take place at equal distances from noon. Or the same thing may be done by means of a luminous object placed at a distance, and so elevated, that an artificial horizon may give its double altitude before and after the coloured glases are reverfed in position. The best artificial horizons are either a veil of pure mercury, with a roof of good glafs framed over it to prevent agitation by the wind; or otherwise a piece of black glafs, well polished, and placed on ferows of adjuftment, with a good spirit-level in a glafs tube, so ground, that it will reverfe in position, and will place the glafs in a perfect level in the two requisite directions, at right angles to each other.

It may be proper to examine further if the two holes in the sight-vane are so made that the sun or other luminous body dazzles the eye more in looking through one, than in looking through the other, the intention being that one shall take in more of the silvered part, and the other more of the unsilvered part of the glafs, so as to accommodate the quantity of direct light to the strength of the eye.

Illustration of the Use.—When Hadley's octant, or sextant, is used for altitudes at sea, the sun, moon, or star, as the case may be, must be viewed in the way that the eye can bear, with or without the dark glases, telecope, &c., as occasion may require, and as experience will dictate; and in a fore observation the body observed must have its image brought gradually down, so as to be in exact contact with

the
the horizon: if the sun or moon be observed, either the upper or lower limb must be substituted for the centre, and
the observation must be afterwards reduced to the centre, by
applying the demi-diameter, + or —, from the proper column
for the given day, as given in the Nautical Almanac, or Epher-
meris; in doing this, the face of the observer must be turned
towards the object whose altitude is to be measured, and
while the image is gradually moved forward along the limb,
the image will defend till it approaches the horizon; in
this situation, let the flow motion by the tangent screw, if
any, bring this image till one of its limbs coincides with the
horizon seen through the transparent slit, and the observed
altitude will be determined as before. Whenever the horizon
is clear both before and behind the observer, he may revere
his instrument and also his body halfealy, when the fun is on
the meridian, and make the fore and back observations check
each other, which will also, from time to time, prove the
respective positions of the two mirrors, and lead to a detection
of the error of the back horizon-glas, when that of the
former is known, which it may always be from a double
measure, one back and one forwards, of the fun's diameter.
If the difference of the altitudes of the same body taken
both ways be equal to the known index-error of the fore
horizon-glas, it will be known that the back horizon-glases
have no error; but if the said quantities are not the same, their
difference, + or —, will be the index-error of the back
horizon-glas; hence the back horizon-glas may be adjusted
from a knowledge of the error of adjustment of the fore
horizon-glas, which method, we believe, was never before
fugugled.

**Quadrant, Hadley's, Theory of.** It is a first principle
in optics, that the angle of incidence, whatever be the
inclination of the incident ray, is equal to the angle of reflection,
that of the angle of reflection DBC will be also 30°. It is also plain, that
if while the radiant A (Plate II. Navigation, fig. 1 and 2.)
remains in the same plane, the mirror E F, by revolving
round B, moves into the position F, then the alteration in
the angle between the incident and reflected ray will be
double to the angle shewing the change of position in the
mirror. Suppose the mirror changes 10° from the radiant,
then the perpendicular BD goes 10° farther from the radiant
A into the position Bd; and the incident angle
DBC is 40°, and the reflected angle DBe is 40°; so the
angle ABC is altered from 60° to 80°; a difference of 20°
for 10° change of position in the mirror. Suppose again
the mirror to change, in position, 10° towards the radiant
A, then the perpendicular is changed into Bd, 10° nearer
to the radiant; and the angle DBC of 30° becomes DBe
of 20° = DB e; so that the angle A Be is 40°, whereas
ABC was 60°; that is, by altering the position of the
mirror 10°, the angle ABC was altered 20°. It may be
otherwise demonstrated, that with a Hadley's quadrant, the
elevation of which an object is seen, is equal to
twice the arc which the index has passed over. The
instrument or angle A C B (fig. 3.) is 45°; ab is a reflecting
glas fixed parallel to CB; CD is the index with a reflecting
glas at G, so fixed as to be parallel to ab, when
CD coincides with CB; S the sun; SC a solar ray re-
lected from G to F, and from F to E, the place of the eye;
and HBE the horizontal line at the time of the
observation. Then will the angle of elevation IGS be equal
to twice the angle BCD; for the angle of reflection DGF
is the angle of incidence SG C = CGL. And the angle
of reflection LE = the angle of incidence a FG = FLE
(ab being parallel to LE) = FEL. But 1GC =
HPC = PEC + PEC (the external angle being equal
to the internal and opposite) = PEC + FLE =
PCE + GCL + CGL. Or, 1GC = IGS + SGC = PCE (or GCL) GCL + CGL = 2BCD +
CGL. Consequentely 1GS = 2BCD. See Robertson's
Mr. Mitchell has recommended Hadley's quadrant for
surveying, and especially the surveying of harbours, and also
for piloting ships into harbours. Phil. Trans. vol. lv.
art. 10. p. 70.
If the final quadrant be taken for a fourth part of the meridian, one side thereof, A B, may be taken for the common radius of the meridian and the equator; and then the other, A C, will be half the axis of the world. The degrees of the circumference, B C, will represent degrees of latitude, and the parallels to the side A B, assumed from every point of latitude to the axis A C, will be radii of the parallels of latitude, as likewise the sine-complements of those latitudes.

Suppose, then, it be required to find the degrees of longitude contained in 83 of the lefser leagues, in the parallel of 48°. Lay the thread over 48° of latitude, on the circumference, and count thefe 83 leagues, on A B, beginning at A; those will terminate at H, allowing every small interval four leagues, and the interval between the broad lines twenty leagues. Then tracing out the parallel H G, from the point H to the thread; the part A G of the thread shews that 125 greater, or equinoctial leagues, make 6° 15', allowing twenty leagues to a degree, and three minutes for one league; and therefore that 83 lefser leagues A H, which make the difference of longitude of the course, and are equal to the radius of the parallel G I, make 6° 15' of the said parallel.

If the fhip fail on an oblique course, such course, besides the north and south greater leagues, gives lefser leagues easterly and westerly; to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones, we must find a mean proportional between them.

To find this, we have on the instrument a scale of eighths of degrees. Suppose, then, it was required to find a mean parallel between the parallels of 40° and 60°. With your compasfes take the middle between the 40th and 60th degree on the scale: this middle point will terminate against the 51st degree, which is the mean parallel required.

QUADRANT, Ufe of the Sinical. There are formed triangles upon this instrument similar to that made by a ship's way, with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants, and the lines N. and S.E. and W.

The lines and arcs are distinguished, every fifth, by a broader line; so that if each interval be taken for one league, there will be five between one broad line and another; and if every interval be taken for four leagues, then there will be twenty leagues, which make a sea degree, from one broad line to the other.

Now, suppose a ship to have failed 150 leagues northwards, one fourth north; which is the third point, and makes an angle of 33° 45' with the north part of the meridian. Here are given two things; viz. the course, and the diſtance failed; by which a triangle may be found on the instrument, similar to that made by the ship's course, and her longitude and latitude; and hence may the unknown parts of the triangle be found.

Thus, supposing the centre A to represent the place of departure; count, by means of the concentric arcs, along the point the fhip failed on, as A D, 150 leagues from A to D; then is the point D the place the fhip is arrived at, which note. This done, let D E be parallel to the side A C; and there will be formed a right-angled triangle A E D, similar to that of the ship's course, difference of longitude, and latitude: the side A E gives 125 leagues for the difference of latitude northwards; which makes 6° 15', reckoning twenty leagues to a degree, &c. and the side D E gives 83 lefser leagues answering to the parallels; which
QUA

which being reduced, as shown above, gives the difference of longitude. And thus is the whole triangle found.

QUADRANT, in Gunnery, called also the gunner's square, is an instrument serving to elevate or point cannons, mortars, &c. according to the places they are to be levelled or directed to.

It consists of two branches, made of brass or wood; one about a foot long, eight lines broad, and one line in thickness; the other four inches long, and of the same thickness and breadth as the former. Between these branches is a quadrant divided into ninety degrees, beginning from the shorter branch, and furnished with a thread and plummet. See its figure represented in Plate I. Gunnery, fig. 5.

The use of this instrument is easy; nothing more being required but to place the longest branch in the mouth of the cannon or mortar, and elevate or lower it, till the thread cuts the degree necessary to hit a proposed object. See Pointing of a Gun.

Sometimes, also, on one of the surfaces of the long branch, is noted the division of diameters, and weights of iron bullets; as also the bores of pieces. See Caliber.

QUADRANT of Altitude, is an appendage of the artificial globe, consisting of a lamina or fih of brass, the length of a quadrant of one of the great circles of the globe; and divided into ninety degrees.

At the end, where the divisons terminate, there is a nut riveted on, and furnished with a screw, by means of which the instrument is fitted on to the meridian; and is moveable round upon the riet, to all points of the horizon. See its figure in Plate XIX. Astronomy, fig. 9.

Its use is to serve as a scale in measuring of altitudes, amplitudes, azimuths, &c. See the manner of its application under the Use of the Globe.

QUADRANTAL, in Antiquity, a vessel in ufe among the Romans for the measuring of liquids.

It was at first called amphora; and afterward quadrantal, from its form, which was square every way, like a dice.

Its capacity was eighty libras, or pounds of water, which made forty-eight sextaries, two urnae, or eight congii.

QUADRANTAL Space, in Geometry. See Quadrant.

QUADRANTAL Triangle, is a spherical triangle, one of whose sides at least is a quadrant of a circle, and one of its angles a right angle.

QUADRANTATA TERRA, in our Ancient Law Books, is used for a quarter of an acre, now called a rood; which fea.

QUADRAc ISLES, in Geography, islands situated on the N.W. coast of North America, between Pintard's found and the straits of Fuca; among which lies Nootka's found, which fea. They were so called by Capt. Ingham, after the name of a Spanish commander of two schooners, who passed through this channel in the year 1792.

QUADRAT, Quadratum, called also geometrical square, and line of shadows, is an additional member on the face of the common Guater's and Sutton's quadrants; of some use in taking altitudes, &c.

The quadrat more distinctly exhibited in Plate VI. Surveying, fig. 15. has each of its sides divided into a hundred equal parts, commencing from the extremes; so that the number 100 falls on the angle, representing tangents to the arc of the limb.

The divisons are distinguished by little lines from 5 to 5, and by numbers from 10 to 10; and the divisons being occasionally produced across, form a kind of lattice, confiting of 10,000 little squares.

The proportion here is, as radius is to the tangent of the angle of altitude at the place of observation (i.e. to the parts of the quadrat cut by the thread), so is the distance between the station and the foot of the object, to its height above the eye. See Altitude.

Use of the Quadrat, Geometrical Square, or Line of Shadows.

1. The quadrat being vertically placed, and the sights directed to the top of the tower, or other object, whose height is required; if the thread cut the side of the quadrat marked right shadows, the distance from the base of the tower to the point of station is less than the tower's height. If the thread falls on the diagonal of the quadrat, the distance is just equal to the height. If it fall on that side marked verfed shadows, the distance exceeds the height.

Hence, measuring the distance, the height is found by the rule of three; inasmuch as there are three terms given. Indeed, their disposition is not always the same; for when the thread cuts the side of right shadows, the first term in the rule of three ought to be that part of the side cut by the thread; the second, the side of the square; and the third, the distance measured. If the thread cut the other side, the first term is the whole side of the square; the second, the parts of the side cut by the thread; and the third, the distance.

For an instance of each. Suppose, r. gr. in looking at the top of a steeple, the thread cut the side of right shadows in the point 40, and that the distance measured 20 poles, the case then will stand thus: as 40 is to 100, so is 20 to a fourth term, which we find to be 50; the height of the steeple in poles. Again, supposing the thread to fall on the other side, in the point 60, and the distance measured 35 poles; the terms are to be disposed thus: as 100 is to 60, so is 35 to a fourth term, viz. 21, the height required. See Altitude.

Use of the Quadrat without Calculation.—The preceding cases may be formed without calculation, where the divisons of the square are produced both ways, so as to form the area into little squares.

Thus, suppose, 1. The thread to fall on 40 in the side of right shadows, and the distance be measured 20 poles; seek among the little squares for that perpendicular to the side which is 20 parts from the thread; this perpendicular will cut the side of the quadrat next the centre, in the point 50, which is the height required in poles.

2. If the thread cuts the side of veered shadows in the point 60, and the distance be 35 poles; count 35 parts of the side of the quadrat from the centre; count also the divisons of the perpendicular from the point 35 to the thread, which will be 21, the height of the tower in poles.

Note, In all cases the height of the centre of the instrument is to be added. See Altitude, and Shadow.

QUADRAT, in Astrology, called also Quadrile, an aspect of the heavenly bodies, in which they are distant from each other a quadrant, or ninety degrees. See Aspect.

QUADRAT, in Printing, is a sort of space; that is, a piece of metal, cast like the letters, to be used occasionally in composing, in order to form the intervals between words, at the end of lines, &c. See Printing.

There are quadrats of divers sizes, as m quadrats, n quadrats, &c. which are respectively of the dimensions of such letters.

QUADRATA, in Ancient Geography, a town of Higher Pannonia, placed on the banks of the Savo by Antone's itinerary.

QUADRATA, in Geography, a town of Naples, in the province of Bari; five miles N.W. of Ruvo.

QUADRATA is the Italian term in canto fermo for Gregorian or square black notes.

U 2 QUADRATA
QUADRATA Legio, among the Romans. See Square Legion.

QUADRATIC EQUATION, in Algebra, is an equation in which the highest power of the unknown quantity rises only to the second degree. If this power enters alone, it is called a simple quadratic; and when the second power and simple quantity both occur, it is termed an affixed quadratic equation, thus:

\[ x^2 + ax = b, \]

is then called an affixed quadratic, and

\[ x^2 = b, \]

or \( a x^2 = b, \) a simple quadratic equation.

Some authors classify all such equations as contain two different powers of the unknown quantity, the one being the double of the other, under the general term quadratics, such as \( x^2 + a x^3 = b, \) \( x^3 + a x^4 = b, \) &c. each of which is called a quadratic equation, because their solution depends upon precisely the same principles as the former.

Every quadratic may be reduced to the form \( x^2 + ax = b; \) in which it is, however, to be understood that \( a \) and \( b \) may be either positive or negative; and the general solution of it is expressed by the formula

\[ x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)} \]

If we give to \( a \) and \( b \) all the variety of signs they admit of, quadratic equations may be divided into four distinct classes, viz.:

1. \( x^2 + ax = -b \)
2. \( x^2 - ax = -b \)
3. \( x^2 + ax = +b \)
4. \( x^2 - ax = +b \)

and their several roots will be exhibited by the following formulae, viz.:

1. \( x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)} \)
2. \( x = \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)} \)
3. \( x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)} \)
4. \( x = \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)} \)

See Equations.

From these forms it is obvious that every quadratic equation has two roots arising out of the ambiguous sign \( \pm, \) prefixed to the second member of the root. It is also obvious, that if in the 1st and 2d form, \( b \) be greater than \( \frac{a^2}{4}, \) the two roots in both forms are imaginary, or impossible; but if \( b \) be less than \( \frac{a^2}{4}, \) they are in each form both real, being in the 1st both negative, and in the 2d both positive; because the quantity exhibited under the radical form is, in both equations, less than that without the radical; and consequently both the sum and difference will have the same sign as \( \frac{a}{2}. \)

In the 3d and 4th forms, the roots are necessarily both real, but one positive and the other negative; the 3d form having its greatest root negative, and 4th its greatest root positive; as is obvious by inspection.

It is, however, not necessary to consider quadratic equations under these four forms, as the solution of them all may be reduced to one general rule, as exhibited in the preceding part of this article, and which may be given in words as follows. Having reduced the proposed equation to any one of the above forms, the roots of it will be equal to half the coefficient of the second term, with its sign changed; plus and minus the square root of the square of that half coefficient prefixed to \( b, \) with its proper sign, whether plus or minus. The principles on which the preceding formulæ are obtained, are these, viz. \( \left(x \pm \frac{a}{2}\right)^2 = x^2 \pm a x + \frac{a^2}{4}; \) therefore, if an equation be proposed under the form \( x^2 \pm a x = \pm b, \) by adding \( \frac{a^2}{4}\) to both sides, we still preserve the equality, and render the first side a complete square, that is, we have

\[ x^2 \pm a x + \frac{a^2}{4} = \frac{a^2}{4} + b; \]

and, by extraction,

\[ x \pm \frac{a}{2} = \pm \sqrt{\left(\frac{a^2}{4} + b\right)}; \]

consequently

\[ x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)}, \]

which form includes all the preceding formulæ. We shall not here give the solution of any examples, as the reader will find sufficient exercises under the article Equation; but it may not be amiss to shew other methods of obtaining the roots of quadratic equations, viz. by lines and tangents, continued fractions, &c.

The Solution of Quadratic Equations by means of a Table of Sines, Tangents, &c.—Here, referring to our preceding four forms, the solution of them may be exhibited as follows:

Form 1. \( x^2 + ax = -b. \)

Put \( \frac{2}{a} \sqrt{b} = \tan. \ z; \) then

\[ x = \left\{ \begin{array}{l} \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)} \\ -\frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)} \\ \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)} \\ \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)} \end{array} \right. \]

See Equations.
QUADRATIC EQUATION.

Substituting again for \( x \) as above, we obtain

\[
x = \sqrt{b + a \sqrt{b + a x}}
\]

and by continuing thus our successive substitutions for \( x \), we have

\[
x = \sqrt{b + a \sqrt{b + a \sqrt{b + a x}}}
\]

which is an analytical expression for the positive value of \( x \) in the proposed equation.

It is obvious, however, that such an expression as this is of little or no use for solving quadratic equations; but we have by means of the latter, a very ready means of finding the ultimate value of such a continued fraction. Suppose, for example, the value of the following continued fraction were required, viz.

\[
\sqrt{12 + \sqrt[3]{12 + \sqrt[4]{12 + \sqrt[5]{12 + \text{&c.}}}}}
\]

Assume

\[
x = \sqrt{12 + \sqrt[3]{12 + \sqrt[4]{12 + \sqrt[5]{12 + \text{&c.}}}}}
\]

By squaring both sides

\[
x^2 = 12 + \sqrt[3]{12 + \sqrt[4]{12 + \sqrt[5]{12 + \text{&c.}}}}
\]

Or, since the latter part

\[
\sqrt{12 + \sqrt[3]{12 + \sqrt[4]{12 + \sqrt[5]{12 + \text{&c.}}}}}
\]

this becomes

\[
x^3 = 12 + x, \text{ or } x^3 - x = 12;
\]

whence

\[
x = \frac{1}{2} + \sqrt[3]{\frac{24}{2}} = 4,
\]

which is the value of the infinite fraction proposed.

Again, let there be proposed the following infinite fraction, viz.

\[
\sqrt{5 + 4 \sqrt[3]{5 + 4 \sqrt[4]{5 + 4 \sqrt[5]{5 + \text{&c.}}}}}
\]

Assume the infinite sum \( = x \), then by squaring

\[
x^2 = 5 + 4 \sqrt[3]{5 + 4 \sqrt[4]{5 + 4 \sqrt[5]{5 + \text{&c.}}}}
\]

whence

\[
x = \sqrt[4]{5 + \sqrt[5]{5 + \sqrt[6]{5 + \text{&c.}}}}
\]

or, by substituting for \( x \), under the radical, its whole value \( \sqrt{b + a x} \), we have

\[
x = \sqrt{b + a \sqrt{b + a x}}
\]

or \( x = 294 \ 176 \ 176 \) the positive root; and if cot. \( \frac{1}{2} \) \( z \) be taken instead of \( \tan. \frac{1}{2} \) \( z \), the other value of \( x \) will be found = -1.5624096. See Bonncastle's Algebra, vol. i. p. 141.

For the solution of quadratic equations by the method of continued fractions, we must refer the reader to the "Essai pour la Théorie des Nombres," by Le Gendre.

The root of a quadratic equation may be exhibited under the form of a continued fraction, as follows:

Let \( x^2 - ax = b \), or \( x^2 = ax + b \); then

\[
x = \sqrt{b + a x}
\]

Or, by substituting for \( x \), under the radical, its whole value \( \sqrt{b + a x} \), we have

\[
x = \sqrt{b + a \sqrt{b + a x}}
\]

or \( x = 0.294 \ 176 \ 176 \) the positive root; and if cot. \( \frac{1}{2} \) \( z \) be taken instead of \( \tan. \frac{1}{2} \) \( z \), the other value of \( x \) will be found = -1.5624096. See Bonncastle's Algebra, vol. i. p. 141.

For the solution of quadratic equations by the method of continued fractions, we must refer the reader to the "Essai pour la Théorie des Nombres," by Le Gendre.

The root of a quadratic equation may be exhibited under the form of a continued fraction, as follows:

Let \( x^2 - ax = b \), or \( x^2 = ax + b \); then

\[
x = \sqrt{b + a x}
\]

or \( x = 0.294 \ 176 \ 176 \) the positive root; and if cot. \( \frac{1}{2} \) \( z \) be taken instead of \( \tan. \frac{1}{2} \) \( z \), the other value of \( x \) will be found = -1.5624096. See Bonncastle's Algebra, vol. i. p. 141.

For the solution of quadratic equations by the method of continued fractions, we must refer the reader to the "Essai pour la Théorie des Nombres," by Le Gendre.

The root of a quadratic equation may be exhibited under the form of a continued fraction, as follows:

cumference of circles, or other curves, and of the several parts of it.

Or, more accurately, the quadratrix of a curve is a transcendental curve described on the same axis, the ordinates of which being given, the quadrature of the correspondent parts in the other curve is likewise given. See Curve.

Thus, e. g., the curve A N D (Plate XIII. Analysis, fig. 7) may be called the quadratrix of the parabola A M C, since it is demonstrated, that A P M A = P N, or A P M A = A P X P N, or A P M A = P N X A, a constant quantity, &c.

The most eminent of these quadratrices are, that of Dinostratus, and that of Mr. Tschirnhausen, for the curve; that of Mr. Perks for the hyperbola.

Quadratrix of Dinostratus, is a curve A M m m (fig. 8.) by which the quadrature of the circle is effected, though not geometrically, but mechanically; it is thus called from its inventor Dinostrates.

Its genus is thus: divide the quadrantal arc A N B into any number of equal parts, in N, n, &c. by a continual bisection; divide the radius A C into the same number of parts in the points P, p, &c. Draw radii C N, C n, &c. Lastly, on the points P, p, &c. erect perpendiculars P M, p m, &c. The curve formed by connecting these lines is termed the Quadratrix of Dinostrates.

This curve may be described by continual motion; if we suppose the radius C N by its extreme N to describe uniformly the arc A B, and at the same time a ruler P M, always parallel to itself, to move uniformly along A C, in such a manner that when the ruler P M arrives at C, the radius C N may coincide with C B; and thus the continual interection of C N with the ruler P M will describe the quadratrix A M D.

Here, from the construction, A N B = A M :: A C : A P, and therefore, if A N B = a, A C = b, A N = x, A P = y; a y = b x. See Quadrature.

Quadratrix Tschirnhausiana, is a transcendental curve A M m m B (fig. 9.) by which the quadrature of the circle is likewise effected; invented by Mr. Tschirnhausen, in imitation of that of Dinostrates.

Its genus is thus conceived: divide the quadrant A N B, and its radius A C, into equal parts, as in the former; and from the points P, p, &c. draw the right lines P M, p m, &c. parallel to C B; and from the points N, n, &c. the right lines N M, n m, &c. parallel to A C. The points A, M, m, being connected, the quadratrix is formed; in which A N B = A M :: A C : A P. And therefore, if A B = a, and A C = b, A N = x, and A P = y; a y = b x. See Quadrature.

This curve may be also described by continual motion, if two rulers, N M and P M, perpendicular to each other, be made to move uniformly and parallel to themselves, the one along the quadrant of the circle A C, and the other along the radius.

Quadratum-Cubii, Quadrato-Quadrato-Quadraturn, and Quadratum Surdofidisi, &c. are names used by the Arabs for the sixth, eighth, and tenth powers of numbers. See Power.

Quadratum Os, in Comparative Anatomy, as carried of the French; a small bone in the head of birds, to which the lower mandible is articulated. See Birds, in Comparative Anatomy, in the division relating to the bones.

Quadrature, in Geometry, signifies literally the finding of a square equal in area to any given figure, which was the method the ancients made use of when they had in view the determination of the surface of any space; but

the term quadrature has now a more indefinite signification; implying, in general, the determination of the area of a figure, without any reference to the geometrical exhibition of it, in a square or other rectilinear form.

All rectilinear figures being immediately reduced to, or dependent upon, the area of triangles, their quadratures have been known from the highest antiquity; but the quadratures of curvilinear spaces are, with very few exceptions, of modern date, two only having been known till near the beginning of the eighteenth century.

The first curvilinear space whose quadrature was accurately determined, was the lune of Hippocrates, of which an account will be found under the article Lune. Archimedes next found the area of the common parabola; which he obtained in a very ingenious manner, by inscribing an isosceles triangle in the parabola, then two isosceles triangles on the equal sides of the former, four others on these, and so on, which he found to have a certain relation, decreasing in the proportion 1, 1/3, 1/7, &c., the infinite sum of which series would therefore express the area of the parabola, or the area of all the triangles which he thus conceived it to be composed; and which sum he found to be 1/3 or 1/2 of the circumscribing rectangle. After this time, a period of near two thousand years elapsed, without producing the quadrature of a single curvilinear figure, although the subject seems to have engaged the attention of the most eminent mathematicians during that long interval, particularly the quadrature of the circle. This figure, being the most simple in appearance and construction of any contained under a curve line, was well calculated to excite the curiosity of mathematicians. Archimedes doubtless attempted the solution of this problem, but failing in producing the exact quadrature, he contented himself with giving an approximation, shewing by the inscription and circumcription of a polygon of ninety-six sides, that the diameter being 1, the circumference was greater than 3 1/7, but less than 3 10/7; and as it was known, even before the time of Archimedes, that the area of a circle is equal to that of a right-angled triangle, whose altitude is equal to the radius, and base equal to the circumference of the circle, it follows, that the area would be greater than 3 11/7, but less than 3 16/7.

It would be useless to attempt in this place to enumerate the various absurd quadratures which have been, from time to time, published by minor geometers, with all that conceit and confidence which seldom fail to accompany inferiority. Some attributed their success to divine inspiration; others to their own superior talents: some offered large sums of money to those who should discover any error in their investigation, while others expected great rewards from their government, as a recompence for their discovery, foolishly attaching great importance to a problem, which, if it could be accurately solved, would serve no other purpose but to gratify the curiosity of mathematicians. Many of these attempts, however, have been rendered somewhat amusing by an excess of absurdity. This is particularly the case with regard to the work of Jaime Falcon, a Spaniard of the order of Notre Dame, of Montesa, published at Anvers in 1587. This treatise opens with a dialogue in verse between himself and the circle, which thanks him very affectionately for having squared him; but the good and modest knight attributes all the honour of the discovery to the holy patron of his order. See Montucla's "Histoire des Recherches fur la Quadrature du Circle," or his "Histoire des Mathematiques," vol. iv. p. 619.

Referring those readers who have the curiosity to examine the reveries above-mentioned to the two preceding works, we propose to give here an abstrat from the same, of what has
QUADRATURE.

has been done on this subject, by way of approximation. We have already observed that Archimedes was the first who gave an approximation of the ratio of the diameter to the circumference of a circle, placing it between the limits $1 + \frac{1}{3}$ and $1 + \frac{2}{3}$; and it is said that Apollonius and Philo found more accurate approximations, which, however, have not been transmitted to us.

Towards the year 1585, Metius, combating the false quadrature of Simon Duchêne, gave the ratio of $\frac{113}{70}$ to $\frac{355}{217}$, which is very exact, being only $\frac{1}{70}$ in excess. Vieta found a still nearer approximation, carrying it to ten decimals, whereas the former is true only to six places. He also gave a kind of series, the infinite sum of which was equal to the entire circle.

Adrianus Romanus carried the approximation to seventeen figures, and Ludolph van Ceulen to thirty-six; which he published in his work "De Circulo et Adscriptis," and of which Snellius published a Latin translation in 1619. He afterwards verified Van Ceulen's approximation by some theorems of his own invention, which greatly facilitated the computation, and which he published in 1621, under the title of "Willebridi Snelli Cycloitricon de Circuli Dimensione, &c."

Descartes found a geometrical construction from which it was easy to draw an expression in the form of a series; and Huygens afterwards discovered some curious theorems connected with this subject, but did not advance the approximation, though he made some useful rules for approximating towards the length of the circular arc.

One of the most curious discoveries connected with this subject, which had yet been published, was that given by Wallis, in his "Arithmetica Infinitorum," in 1655; where he shews that the ratio of a circle to the square of its diameter, is truly expressed by the infinite fraction

$$\frac{\pi}{2} = \frac{3}{1} - \frac{3^2}{2} + \frac{5}{2} \frac{5^2}{2} - \frac{7}{2} \frac{7^2}{2} + \frac{9}{2} \frac{9^2}{2} - \ldots$$

If we limit ourselves, as we must do, to a finite number of terms, we shall have a ratio alternately too great and too small, according as we take an even or an odd number of terms:

thus, \(\frac{3}{2}\) is too great, \(\frac{3^3}{2^2}\) too small, \(\frac{3^3}{2^2}\) too great, and so on.

3.3.5.5 too small, and 3.3.5.5 too great, according as we take an even or an odd number of terms:

2.4.4.6 too small, and 2.4.4.6 too great.

3.3.5.5 too small, and 3.3.5.5 too great.

In excess.

3.3.5.5 2.4.4.6
3.3.5.5 2.4.4.6
3.3.5.5 2.4.4.6
3.3.5.5 2.4.4.6

Prior to the above series of Dr. Wallis, however, some thing of an equivalent expression, though given under a different form, was discovered by lord Brouncker, which is as follows. The circle itself being 1, the square of its diameter is expressed by the infinite continued fraction:

$$1 + \frac{1}{2 + \frac{3}{2 + 5}}$$

of which the law of the denominators is obvious. See Circle.

Such was the progress which mathematicians had made towards the solution of this interesting problem prior to the invention of fluxions, which, by reducing the quadrature of all curves to one general principle, again revived the hopes of success with regard to the circle, notwithstanding some pretended demonstrations of its imposibility; and its quadrature was accordingly again attempted with the greatest eagerness. The quadrature of a space, and the rectification of a curve, were now reduced to that of finding the fluent of a given fluxion but the problem was found to be incapable of a general solution in finite terms. The fluxion of a given fluent was found to be always affinable, but the converse proposition, viz. of finding the fluent of a given fluxion, could only be effected in particular cases; and amongst the exceptions, to the great regret and disappointment of geometers, was included the case of the circle with regard to every form of fluxion under which it could be obtained. Some exceedingly near approximations have, however, since been made towards the true ratio of the diameter to the circumference of the circle, but these belonging rather to the article Rectification than to Quadrature, we shall enter again upon the subject under the former term, and shall occupy the remainder of the present article on the quadrature of curves in general.

On the Quadrature of Curves by Fluxions. In order to exhibit more distinctly and at large the use of fluxions, according to the modern method of notation, in finding the areas of curves, we shall premise the two following cases.

Cafe 1. — Let A R C (Plate XII). Analysis, fig. 10.) be a curve of any kind, whose ordinates R, B, C, B, are perpendicular to an axis A B: Imagine a right line b R, perpendicular to A B, to move parallel to itself from A towards B; and let its velocity, or the fluxion of the absciss b a, in any supposed situation of that line, be denoted by b d; then will the rectangle b a express the fluxion of the generated area A b R, which (if A b = x, and b R = y) will be

$$x = \frac{d}{2}$$

whence, by substituting for y or x (according to the equation of the curve,) and taking the fluent, the area itself will become known.

Cafe 2. — Let A R M (fig. 11.) be any curve whose ordinates C R, C R, are all referred to a point or centre, and conceive a right line C R, H to revolve about the given centre C, and a point R to move along the said line, so as to describe the curve live A R M. If this point were to move from Q, without changing its direction or velocity, it would proceed along the tangent Q S (instead of the curve), and describe areas Q, Q C, Q S, C, about the centre C, proportionate to the times in which they were described; because, having the same altitude C P, they are as the bafes Q S and Q S. Consequently, if R S be taken to denote the value of $\frac{1}{2}$ the fluxion of the curve line A R, the corresponding fluxion
QUADRATURE.

The fluxion of the area A R C will be justly represented by the uniformly generated triangle Q C S; which, expressing C P by $t$, will be $\frac{Q S \times C P}{2} = \frac{z}{2}$; whence the area itself may be determined. But since, in many cases, the value of $z$ cannot be computed (from the property of the curve) without trouble, the two following expressions, for the fluxion of the area, will be found more commodious, viz. $\frac{z \times y}{6} + \frac{z \times x^2}{24}$, where $t = R P$, and $x = \frac{x}{R}$, are the arc B N of a circle, described about the centre C, at any distance $a = C B$. These expressions are derived from that above in the following manner; viz. $z : y : y (C R) : t (R P)$; therefore $z = \frac{y^2}{t}$; consequently $\frac{z}{y} = \frac{y}{2}$. Moreover, because the celerity of $R$ in the direction of the tangent is denoted by $x$, that in a direction perpendicular to $C Q$ (where the point $R$ revolves about the centre $C$) will, therefore, be $\frac{C P \times z}{y} = \frac{z}{2}$; which, being to $x$ the celerity of the point $N$ about the same centre as the distance or radius $C R$ ($y$) to the radius $C N$ ($a$), we shall, by multiplying extremes and means, have $\frac{a z}{y} = \frac{y x}{a}$, and, consequently, $\frac{z}{y} = \frac{x}{2}$. In the examples subjoined, the letters $x, y, z, w$ and $u$ will be used to denote the abscissa, ordinate, curve-line, and area respectively.

QUADRATURE of a Right-angled Triangle. Let the base $A H$ (fig. 12.) = $a$, the perpendicular $H M = b$, and let $A B (x)$ be any portion of the base, considered as a flowing quantity, and $B R (y)$ be the corresponding ordinate. Then, the triangles $A H M$ and $A B R$ being similar, we shall have $a : b : x : y = \frac{b x}{a}$; Whence $x \times$ (the fluxion of the area $A B R = \frac{b x}{a}$); and its fluent (see Inverse Method of Fluxions) or the area itself = $\frac{b x^2}{2 a}$, which, when $x = a$, and $B R$ coincides with $H M$, will become $\frac{a b}{2} = \frac{A H \times H M}{2}$ = the area of the whole triangle $A H M$. See Mensuration of Triangles.

QUADRATURE of a Circular Sector. Let $A O R$ (fig. 13.) be the sector; $A O$ or $O R$, its radius, = $a$, the arc $A R$, considered as variable by the motion of $R$, = $z$, and $R r = z$; the fluxion of the area will be $\frac{a z}{2} = \frac{z}{2}$.

$O R r$: whence the area itself is $\frac{a z}{2} = O A \times \frac{1}{4} A R$; that is, the area of any circle is expressed by a rectangle under the half circumference and half the diameter. See Circle.

QUADRATURE of a Semicircle. Let the semicircle be $A R E H$ (fig. 14.), its diameter $A H = a$, $A B = x$, and $B R = y$, &c. and we have $y^2 (B R^2) = a x - x^2$ ($A B \times B H$), and, consequently, $u (y \times) = \frac{x^2}{2} \sqrt{a x} - x^2$; which expression being resolved into an infinite series, we shall have $u = \frac{x^2}{2} x^2 \times \left(1 - \frac{x}{2a} - \frac{x^2}{8 a^2} - \frac{x^4}{16 a^4} - \cdots \right) = a^2 \times \left(\frac{x^2}{2} + \frac{x^2}{a} - \frac{x^2}{2} - \frac{x^2}{8 a^2} - \frac{x^2}{16 a^4} \cdots \right)$, &c. Whence, the fluent of every term being taken, there will arise $u = \frac{x^2}{2} \times \left(\frac{x^2}{2} - \frac{x^2}{16 a^4} \cdots \right)$, &c. $\sqrt{a x} \times \left(\frac{x^2}{2} - \frac{x^2}{16 a^4} \cdots \right)$= the area $A B R$. When $x = \frac{a}{2}$, the ordinate $B R$ will coincide with the radius $O E$; in which case the area becomes $= \frac{a^2}{2} \sqrt{a x} \times \left(1 - \frac{x}{2a} - \frac{x^2}{8 a^4} \cdots \right)$.

Quadrature of the Ellipse. The ellipse, also, is a curve whose precise quadrature in definite terms is not yet effected. Indeed the area of an ellipse, being an exact mean proportional between the areas of the circles described upon its two axes, is obviously dependent upon the latter; and it is, therefore, useless to repeat the operation.

QUADRATURE of the Parabola. Let the curve $A R M H$ (fig. 15.), be the common parabola, in which $y^2 (B R^2) = a x$ ($A B \times a$, the parameter). See Conic Sections.

Whence we have $y = \frac{x^2}{a} x^2$, and $u (y x) = \frac{x^2}{a} x^2$; and, therefore, $u = \frac{x^2}{a} x^2 = \frac{2y}{a}$; the fluxion of the ellipse is $\frac{2y}{a} \times \frac{2y}{a} = \frac{2y}{a} \times \frac{2y}{a}$; &c. $\frac{2y}{a} \times \frac{2y}{a}$ = the area $A B \times B R$. Hence a parabola is $\frac{2y}{a}$ of a rectangle of the same base and altitude.

The value of the area may also easily be found in terms of $y$. Thus $x$ being $= y^2$, we have $x = 2y^2$, and $u (y x) = \frac{2y}{a} \times \frac{2y}{a} = \frac{2y}{a} x$; and $\frac{2y}{a} x = \frac{2y}{a} \times \frac{2y}{a}$ = the area $A B \times B R$. See Parabola.

In the cubic parabola, whose equation is $y^2 = x^3$; we have
QUADRATURE.

The analytical quadrature of this curve was first given by N. Mercator of Hol- 
rein, the first inventor of infinite series. But Mercator finding his series by dif- 
inition, Sir Isaac Newton and M. Leib- 
mitz improved upon his method; the one seeking them by the 
extraction of roots, the other by a series precompounded. 
See HYPERBOLA.

**Quadrature of the Asymptotic Spaces in an Hyperbola.** Let DEF (fig. 16.) be an hyperbola, of which the asymptotes are CM and CN; to find the area EGHF, comprehended between the ordinates GE and FH.

Let CG = a, GE = b, CH = x, FH = y, then by the property of the hyperbola, \( CG \times GE = CH \times HF \),
or \( ab = (a - x)y \), or \( y = \frac{ab}{a + x} \); and, therefore, \( y' = \frac{ab}{a + x} \), the fluent of which is \( ab \times \text{hyp. log.} \). 

which fluent, however, requires a correction, for \( x = a \), the area = \( a \); but the above expression is \( ab \times \text{hyp. log.} \), of \( a \), therefore the correction is \( -ab \times \text{hyp. log.} \), that is, the correct fluent which expresses the area is \( ab \times \text{hyp. log.} \).

_log. a, or area EGHF = \( ab \times \text{hyp. log.} \).

If CG and GE each = 1; \( y' = \frac{x}{1 + x} \), the fluent of which is \( \text{hyp. log.} \), which requires no correction.

**Quadrature of the Cycloid.** Let CAL (fig. 17.) be a cycloid, AD the axis, B the generating circle, A a tangent at the vertex, C parallel to AB.

Take any point P in the arc, and draw PM perpendicular to AM. Then the fluxion of the external area AMP = PM \times the fluxion of AM.

Let AE = x, AD = 2a; then BE = \( \sqrt{(2ax - x^2)} \), and the fluxion of BE = \( \frac{(a - x)}{\sqrt{(2ax - x^2)}} \).

Also PB = the arc BA; therefore the fluxion of PB = \( \frac{ax}{\sqrt{(2ax - x^2)}} \); and the fluxion of PB + BE, or of AM = \( \frac{(2a - x)}{\sqrt{(2ax - x^2)}} \), the fluxion of the area AP, or PM, \times by the fluxion AM = \( \frac{(2ax - x^2)}{\sqrt{(2ax - x^2)}} \).

But the fluent of this fluxion is the same as that found above for a circle, whose radius is a, and verified for \( x^2 \); that is, the area ABC and, therefore, when \( x = a \), the whole external area CFA is equal to the area of the semi- 
circle ABD. But CD being equal to the semicircumference AD, the whole rectangle CDAF = four times the semi- 
circle ABD, and consequently the internal area ACD = three times the semicircle ABD; or the whole area of

Vol. XXIX.
Whence, the area of the curve \[= \frac{m}{m + 1} \left(\frac{x + a}{a}\right)^{m} \sqrt{(x + a)} \]

See on the subject of this article Maclaurin's Fluxions, and Simpson's Fluxions, vol. i. sect. 7, p. 121, &c.

**QUADRATURE.** in Astronomy, that aspect, or situation of the moon, when she is 90 degrees distant from the sun.

Or, the quadrature is when she is in a middle point of her orbit, between the points of conjunction and opposition; which happens twice in each revolution, viz. in the first and third quarter.

When the moon is in her quadrature, she exhibits that phasis which we call the half-moon, i.e. the time with just half her face; and is said to be bisected, or dichotomized.

In the moon's progress from the fuzzyge to her quadrature, her gravity towards the earth is continually increasing by the action of the sun; and her motion is retarded for the same reason. Her motion then, in her orbit, is slowest as her gravity to the earth is greatest when in the quadratures.

In her reced from the quadratures to the fuzzyges, the gravity continually decreases, and the velocity increases. The ratio is thus: as radius is to the sun, or difference of one and a half the cosine of double the distance of the moon from the fuzzygy, and half the radius; so is the addition of gravity to the quadratures to the diminution or increase of it in any other situation. See Syzygy.

Hence the moon's orbit is more convex in the quadratures, than in the fuzzyges; and hence the circular figure of the moon's orbit is changed into an oval, whose greater axis goes through the quadratures; and hence, also, the moon is less distant from the earth at the fuzzyges, and more at the quadratures.

It is no wonder, therefore, that the moon should approach nearer the earth when her gravity is diminished; that access not being the immediate effect of this diminution, but of the inflexion of the orbit towards the quadratures.

In the quadratures, and within thirty-five degrees of them, the apfides of the moon go backwards, or move in antecedentia; but they move forwards in the fuzzyges. See Aspides.

The moon's orbit undergoes various alterations in each revolution. Its eccentricity is the greatest when the line of the apfides is in the fuzzyges; and the least, when in the quadratures.

Considering one entire revolution, the nodes move flower and flower as the moon approaches the quadratures, and they meet when she is in them; but considering several revolutions, the nodes go back faster in the quadratures.

The inclination of the plane of the moon's orbit increses as the nodes go from the fuzzyges, and is greatest when the nodes are in the quadratures. See Moon and Nodes.

**QUADRATURE LINES, or Lines of Quadrature, are two lines frequently placed on Gunter's sector.**

They are marked with the letter Q, and the figures 5, 6, 7, 8, 9, 10; of which Q signifies the side of a square, and the other figures the sides of polygons of 5, 6, 7, & c. sides. S there stands for the semi-diameter of a circle; and 90 for a line equal to ninety degrees in circumference.

**QUADRATUS, in Biography, an early Christian writer, who flourished under the reigns of Trajan and Adrian. He is styled by Jerome and Eusebius "a disciple of the apstles," and was reported to have been endowed with the gift of prophecy. According to Eusebius, Quadratus** presented to the emperor Adrian, in the year 126, an apology for the Christian religion, with a view of mitigating the sufferings inflicted upon the professors of that period. This is supposed to have been the first written apology presented on the same subject to any of the Roman emperors, and it produced a considerable effect on the mind of Adrian. Of this work only a fragment remains, which is preserved by Eusebius, and which is extremely valuable on account of the testimony which it affords to the reality of the miracles of Christ and his apostles, by ascertaining that some of those miracles were wrought on persons who were living at the time when Quadratus wrote. Nothing is reported respecting the time and manner of his death. Lardner.

**QUADRATUS, in Anatomy, a name given to several muscles of the body, on account of their form.**

**QUADRATUS Flernoris, le carris, iffibio-trochanteren;** is situated at the upper and back part of the thigh, and extends from the tuberosity of the ischium to the great trochanter. It is flattened, quadrilateral, and tolerably thick. The posterior surface is covered by the gluteus maximus, the ficiac nerve, and the semi-membranous; the anterior surface covers the obturator externus, the extremity of the tendon of the psoas magnus, and the back of the trochanter minor. The superior edge is parallel to the inferior geminus; and the inferior to the upper fibres of the adductor magnus. The inner edge, or origin of the muscle, is fixed to the outer side of the tuberosity of the ischium, in front of the semi-membranous; the outer is attached to the bony ridge, which runs from the great to the small trochanter. It is tendinous at its two attachments, and fleshy in other parts. It will rotate the thigh outwards upon the pelvis; or, if the former be fixed, it will move the pelvis upon the thigh. When the thigh has been carried upwards and outwards, it will restore the limb to its natural position.

**QUADRATUS Genae, a muscle of the lower lip; see the article Deglutition, where it is described under the name defressor labii inferioris.**

**QUADRATUS Lumbarum.** See Lumbarum.

**QUADRATUS Occipitis, a name of the posterior or occipital portion of the Epiphanes; which see.**

**QUADRELLA, in Geography, a town of Naples, in Lavora; 20 miles E.N.E. of Naples.**

**QUADRELS, in Building, a kind of artificial stones, perfectly square; whence their name. They are made of a chalky, or whithish and phable earth, &c. dried in the shade for at least two years.**

They were formerly in great request among the Italian architects.

**QUADRICEPS, in Anatomy, a name under which it has been proposed to describe the extensors of the knee-joint, viz. the vastus internus and externus, the cruræus, and rectus; and the adductors of the thigh, with the peculiars.**

**QUADRIGA, formed from quadrar, four, and jugum, yoke, in Antiquity, a car, or chariot, drawn by four horses, harnessed abreast.**

Various are the accounts we have of the inventor of the quadriga. Cicero makes it the invention of Minerva. Hyginus attributes it to Erichenbonus IV. king of the Athenians; which sentiment Virgil also follows in his Georgics, lib. iii. ver. 111. Ephylus gives Prometheus the honour of it. Tertullian, De Spectac. lib. ix. says, it was invented among the Argians, by Trochilius, in honour of Juno; and at Rome, by Romulus, in honour of Mars, or Quirinus. Ado of Vienna, Chronic. act iii. will have it to have been invented by one Procius, about the time of the establishment of the kingdom of Athens. Lazzardels, Hift.
Hiæ. Univers. Epitom. lib. xxiv. says the name of Triptolemus. Last of all, if there be not opinions enough already, Herodotus gives us another; and says, the Greeks borrowed it from the Libyans. Pliny tells us, that his seal was a quadriga, lib. xvi.

On the reverses of medals we frequently see Victory, or the empress, in a quadriga, holding the reins of the horses; whence these coins are called, among the curious, nummi quadrigati, and violetiati. See Bigati.

Quadriga, from quadrum and jugo, yokes, in Surgery, a bandage for the horned ribs, so called from its resemblance to the trappings of a four-horse car. It was formerly employed in cases of fractured ribs; but, as it is not now in use, a more particular account of it seems unnecessary.

Quadrigemina Corpora, in Anatomy, a part of the brain, known more commonly by the terms nates and testes. See Brain.

Quadrilateral, in Geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure.

If the several angles be right, the figure is a rectangular quadrilateral. If oblique, an oblique-angular quadrilateral.

If the sides of a quadrilateral be equal, and the angles right, the figure is a square.

If the sides be equal, but the angles unequal, the figure is a rhombus.

If the angles be equal, and the sides unequal, the figure is a rectangle.

If only the opposite angles and sides be equal, the quadrilateral is a rhomboid.

If the opposite angles and sides be unequal, the quadrilateral is a trapezium.

If any side of a quadrilateral, inscribed in a circle, be produced out of the circle, the external angle will be equal to the opposite, internal angle.

Hence, the two opposite angles of any quadrilateral figure inscribed in a circle, always make two right angles; and, therefore, no oblique-angled parallelogram can have a circle described about it, because its opposite angles being equal, must together be greater or less than two right angles. See Circle.

Quadrell, Quadrilla, a little troop or company of cavaliers, pompously drest and mounted; for the performance of carousals, jousts, tournaments, running at the ring, and other gallant diversifications.

The word is borrowed from the Italian, being a diminutive of quadrato, a company of followers ranged in a square: for quadrare is, properly, to dispose any thing square; whence their quadriglia, the French quadrille and quadrille, and our quadrille. The French formerly wrote quadrille, and s'quadristre.

A regular carouse is to have at least four, and at most twelve, quadrills.

Of these quadrills, each is to consist of at least three cavaliers, and at most of twelve.

The quadrills are distinguished by the form of their habits, or the variety of their colors.

Quadrille, a well-known game at cards; and which has been, in several cafes, the object of mathematical computations. See M. De Moivre's Doctrine of Chances, 3d edit. p. 97, &c.

Quadrìo, Francesco Saverio, in Biography, a Jesuit, author of a voluminous history and description of every kind of Italian poetry, "Della flora e della Ragione d'ogni Poesia," eight vols. 4to. published at Bologna between the years 1739 and 1752.

The author seems a mere compiler, without selection, taste, or accuracy. It is a heavy work, hardly interesting enough to stimulate a regular perusal; and from the disorder of the arrangement, very difficult to consult. Creceimbì is as superior to Quadro as Corpuscularianism is to Averroism.

Quadripartit, the dividing by four; or taking of the fourth part of any number, or quantity.

Hence quadrupartite, &c., something divided into four.

Quadrieme, Quadrirème, a galleon, or vessel, with four ears on a side; the invention of which was attributed by the ancients to the Carthaginians.

QuadriSetæ, the four-haired flies, a term used by the writers in natural history to express those flies of the fowkade or hair-tailed kind, which have four hairs or bristles growing from the tail, as the others have three, two, or one.

Quadriu, the centre of four ways, where four roads meet and cross each other. By statute, posts with inscriptions are to be set up at such crofs-ways, as a direction to travellers, &c. 8 & q W. III. c. 10.

Quadriu, besides the centre of four ways, was a scholastic division, used in the middle ages in our universities, to express the highest class of philosophical learning and science; comprehending arithmetic, geometry, astronomy, and music: as the trivium did grammar, rhetoric, and logic. During this period, music, such as it was, must have been highly prized to be ranked with the most sublime sciences, and thought an essential part of a learned education.

Quadro, Ital. literally means square, and in music, at present, it implies a natural, h, or Gothic B, in opposition to tondo, round, or the round b, used for a flat. The durum hexachord is sometimes called the quadro hexachord, from the circumference of B being h.

It was the opinion of Padre Martini and the prince abbot of St. Blaisius, that accents and points, enlarged, disfigured, and lengthened, became musical characters for time as well as tune. At first, when lines and spaces were used, from their being chiefly employed in a square form for writing the chants established by St. Gregory, they acquired the name of Gregorian notes, quadrata, and in barbarous Latin, quadrata. As the church is now in receiving new doctrines, and generally a century later in admitting those improvements or corruptions in music (the reader may call them which he pleases) that are adopted by the laity as the fortunate efforts of cultivated genius, the notation of chants was at first cenured and prohibited by several councils; and figurative harmony being regarded as a crying sin by pope John XXII., was formally excommunicated by a bull from the concave 1521. See Notes, and Time-Table.

Quadragata Tertie, in Old Law Records, denotes a team-land; or so much as can be tilled by four horses.

Quadruila, in Natural History, a word sometimes used in the same sense as tesselata, and spoken of the cubic pyrites. Sometimes it is used also as the name of those little spangles of shining matter that are mixed among fandle. Those are generally fragments of pale; and are of various colours, white, yellow, and blackish.

Solinus has used the word quadrula to express the fragments of yellow tale that are found in that sand called ammobrytos, or golden sand. He mistakes these shining particles for malfes of real gold, and makes the sand itself a kind of precious substance ranked among the gems, and brought from Persia; but in this he does not agree with the rest of the ancients.

Quadraped. The essential character of quadrupeds
QUADRUPEDS.

Peds is, that they have a hairy body and four feet, and that the females are viviparous, and give suck to their young. Quadrupeds are distinguished, by the number of their feet, from other animals, which have only two feet, as birds; from those which have no feet, as fishes and reptiles; and from those which have more than two feet, as insects.

Aristotle distributes quadrupeds into three classes: denominating those whose feet are terminated by a hoof in one piece, 

&c. those which have a cloven hoof he distinguished by the name of forked or cloven-footed; and those whose feet are digitated he called "digitated. With this general division he contented himself, without proceeding to a methodical distribution of each class into their several orders, genera, &c. Gegen, Aldrovandus, Jonston, and many other naturalists, have adopted the distribution of Aristotle: but we are indebted for the regular systematic arrangement of quadrupeds to Mr. Ray, who published his "Synopsis Methodica Animalium Quadrupedum et Serpentium generis," &c. in 1693. According to this writer, quadrupeds are divided into those which are hoofed, ungulata; and those which are clawed, or digitate, ungulicula.

QUADRUPEDS, Hoofed, are either,

1. Whole-hoofed, 

2. Cloven-footed; and that either, 1. Into two divisions only; as the Sima, or bifaculate kind; which are again subdivided into such as are,

First. Ruminant, 

Secondly, of animals whose feet are divided into two parts only, and which do not chew the cud, there is only the hog and swine kind. Under this head, besides the common swine, are reckoned the wild boar, or swine; the Guennennis Marcgravii; the porcus Indicus, or babyrnena; the tajacu or aper Mexicanus mofcherus of Dr. Tyson, called, by Marcgrave, tajacu caasiaora; by others, quaubula coymat, and quaquizot; and by Acosta, and some others, zaino.

2. There are some quadrupeds, whose hoof is cloven into four divisions, and though they be not ruminate; as the rhinoceros, the hippopotamus, the tapijereeta of Brail, the capybara of Brail, and the animal mofcherum.

QUADRUPEDS, Cloven or Digitate. Of this kind, there is, first, a sort whose claws are not divided or separated, but adhere to one another, and are covered with one common skin; but with obtuse nails, sticking out round the margin of the foot; as the elephant, which is anomalous, and not clearly referrible to this kind, or to that of cloven-footed quadrupeds.

A second species of this digitate kind of quadrupeds, which has only two claws, is the camel; and though these have no horns, they both ruminate, and have also the four Romach of horned ruminate animals.

Of the camel there are two sorts; one having but one hunch on the back, the other two.

To this kind also belong the Pervian glama, which some have reckoned among the lizard kind; as also the paco, the ovis Indica, or Peruvian vulgo, which is much less than the glama.

A third species of this ungulate kind includes such animals as the Greeks called "Pfaffwoc," and "Aphraia," which have the foot divided into many claws, with broad nails on them; as the ape and monkey kind. Of these, some have no tails, and are called simiae, or apes; others have tails, and are called monkeys, cercopitheci; and such as have either long or short tails, if they are of a larger size, are called papiones, or baboons. There are great numbers and varieties of this species of quadrupeds; of which naturalists have described these, viz. the orang-ontang, or homo sylvestris of Dr. Tyson, described by him in a particular difcours; the guariba of Brail, Marcgravii; the cagiu of Brail, greater and leffer; the eay of the fame region, described by Lerus; the caitaia of the fame country; the cercopithicus barbatus Guennensis; two or three forts of it; the cercopithicus Angolensis major; the cercopithicus non barbatus Clusi; the cercopithicus Cluf. called lagouin. Lastly, if apes and monkeys have their fnovent very prominent, like dogs, they are called cynoccephali.

A fourth species of this ungulate kind is, when, though the claws are many, yet they are not covered at the end with broad flat nails, like monkeys or apes; but are rather like the talons of hawks, &c. crooked and sharp-pointed.

These, in respect of their teeth, may be divided into such as have many dentes primores, or incisors (that is, cutting teeth) in each jaw, of which there are two sorts; a greater, which either have a short, round head, as the cat kind; or a leffer sort, having a long slender body, with very short legs, as the weafl or vermin kind. There are also some of this species of quadrupeds which have only two large remarkable teeth in each jaw; these are the hare kind; and these live only upon herbs, gréfs, &c.

Of the cat kind of quadrupeds are reckoned to be the lion; the tyger; the pardalis, whole male is pardus, and female panthera; the leopard; the lupus cervarius, or lynx; the catus pardus, or cat-amounitain; the common cat; and the bear.

Of the dog kind are reckoned the wolf; the lupus auricus, or jackall; besides the common dog, of which kind they
they enumerate the mallard, or malliff; the canis venaticus Graius, Græcus, or Scoticus, the greyhound; Graius Hibernicus, or the Irish greyhound; the canis venaticus sagax, indagator, sectator ferarum, &c. the hound; canis venaticus Hispanicus, or aviarus, the spaniel for land or water; vertagus, or tumbler; canis Genuae, or domelicus, the houfe-dog; canis melitus, or the lap-dog; canis Getulus, or Illidicus, the jackal; and of all these forts there are many varieties of mongrels, and hybrides breeds.

Other species of the dog kind are, the fox; the animal zibethicum, or civet-cat, as it is corruptly called, but by its teeth and snout is plainly that of the dog tribe; the American coati, or rackoon, or ratteoon; the yzaquepati; the carigueya, maritucca, carigoy, ropoza, or opollifum; the taubii; the taxus, or meles, the badger, grey, or pate; the lutra, or otter. To the fome add the phoca, sea-calf or seal; the equus marinus, morfe, or sea-horce, muitaken by fome for the hippocampus; the Dutch call him walrus, the Danes and Inclanders rofmarus; lafly, the manati, or vacca marina, the sea-cow.

Of the erem or weafel kind of quadrupeds, is, fift, the mutela vulgaris, the common weafel, in Yorkshire called fumart, or fitchet, velifer, the vivera Indica, called quill and quirpifae; another fort called mugno, and munagafa, of a reddifh-grey; the mutela, ermine, or fiolet, and mutela fylvefris, the ferret; putiorus, the pole-cat; martes, or foyna, the martin, or martlet; mutella zibellina, the fable: lafly, the genetta; and the ichephon Belleni.

Of the bare kind of quadrupeds are, firft, lepus, or the common hare; cuniculus, the rabbit, or coney; tapeti, or Brafl, coney, and the aperea of Brafl; the hydrif, or porcupine, and the hydurix Americanus, or cuanda of Brafl; cafior, fiber, or the beaver; ficatus vulg., or squirrel; the Virginian, Zeylandic, Barbary, and American flying squirrel; mus domefticus, and major and minor; the dormoufe or fleeper, mus Noricus, Cidetus, Alpinus, seu marmotta; the cavia cobaya, or cuniculus Americanus, the Guinea-pig; the aguti, and paca of Brafl; the mus Norwegeus, or lefing; the gilis Gefneri, or the rell; the mus Indicus, &c.

Quadrupeds, Anomalous. To thofe feral kinds, the following anomalous ones mufl also be added:

1. Such four-footed viviparous animals as have a longifh snout, with their feet divided into many claws, and toes, and having teeth; as the cuniculus terriferus, or common urchin, or hedge-hog; cuniculus Indicus albus; tatu or armadillo prima of Marcgrave; tatuatae of Brafl, or the fefcond Species of the armadillo, according to Marcgrave; tatuapar, his third species of armadillo; tatu melilitinus, Soc. Reg. Muf. the weafel-headed armadillo; talpa, the mole-warl, or mord-warp; and the mus aranue, fhrew, hardy fhrew, fhrewmouse.

2. Quadrupedous and viviparous animals with a longifh snout, having their feet divided into many claws or toes, but without teeth; as the tamandua guacu of Brafl, Marcgrave, uirus formicarius Cardani, the great antbear; the tamandua of Brafl, or Marcgrave, the letter ant-bear.

3. Anomalous flying quadrupeds, with a shorter fniout, and their feet divided as above; being of the bat kind, or fitter-mice, of which there are feveral fizes, and of different fizes.

4. There is one very anomalous animal, which has but three claws on each foot; and that is the ai or ignavan of Marcgrave, the foth or flaggard.

5. Viviparous and fanguineous quadrupeds, breathing with lungs, but having onluy one ventricle in the heart; as the rana aquatica, the frog, or froth; rana arborea, feu ra-nunculus viridis, the small tree or green frog; bufo, five rubeta, the toad; teftudo, the tortiofe, in Greek δερματα; of thoth there are land and water ones, and many different species in foreign parts.

6. Oviparous quadrupeds, with a long tail ftrretched out horizontally. Such are the lizard kind; as lacertus omnium maximus, the crocodile; cordulus, five caudiverbera, uru-maftrix Græcis, larger than the green lizard; tapaxa Muro Hispanicus, or lacertus orbicularis of Hernandez; lacertus vulgaris, the common eft, sift, or newt; lacertus viridis, the green lizard; lacertus fucctanvs Aldrovandi, at Rome and Naples called the tanartula; lacertus Indicus, called fcnembi and igauna; lacertus Brafielenis, called teju-guaco, and temapara by Marcgrave; the taraiguara ameiva, taragucio Arcuraba, Americana, Curapopohe, Teiunhana, &c. of Marcgrave; the lacertus Indicus; the fcinus, or crocodilus terrifris; the feps, or lacerta chalciidea, a kind of footed serpent; felliio, the sift, or fpotted lizard; fal-mandra, called the falamandra aquatica, the water-eft; lacerta volans Indica; and the chameleo, or caleemon.

This fystem of Mr. Ray obtained very generally among naturalifts, till, in the year 1735, Linneaus firft published his fystem. This was followed by several others, varying in the arrangement of the animal kingdom, even to the laft edition of 1759. Under the clas, which he denominates Mammalia, (which fee,) he comprehends not only all the animals which we call quadrupeds (the lizard genus, or rather the reptiles pedati excepted), but also the cetaceous order, or whales, cachalots, and porfelles: juftifying this arrangement of whales with quadrupeds, from the agreement of thefe animals in the ficructure of the heart, in the reftiration by means of lungs in their having moveable eye-lids and ears, in being viviparous, furnifhed with teeth, and other particulars, by which they differ fo materially from fifies, as more than to counterbalance their living with them in the fame element. The mammalia are divided into feven orders, the dilfinitions of which are principally eftablfhcd on the difference in the numbers, fition, and form of the three kinds of teeth, viz. the primores or incifores, called foce-tooth, or cutting-teeth; the laniari or canini, called dog-teeth, canine or lacerating teeth; and the molares, double teeth or griners. But Linneaus does not entirely neglcet the feet. See the characters of the feral orders under Primates, Brute, Feræ, Glis, Pecora, Bellua, and Cete or Whale. This part of the Linnean fystem, including a few species defcribed in the Appendix of the third tome, and in the Manitifa of 1771, contains about two hundred and thirty five species.

Mr. Pennant, in his "Synopsia of Quadrupeds," and professor Martin, in his "Elements of Natural History," by including fome animals that were unknown to Linneus, and giving the rank of species to feral that were confidered by him as varieties, have extended the number of mammalia to two hundred and eighty-nine fpecies. Mr. Klein, in 1751, published a new fystem of quadrupeds, intitled "Quadrup. Diplofittio brevisque Hiil. Natur." in which he diftributes them into two orders, the firft comprehending thole whose feet are terminated by one or more hoofs, and the fecond thole which are digitated; and each of these orders is subdivided into five families or fhephes. In his firft order he follows the general arrangement of Mr. Ray, which he has considerably improved; but in the fecond, by a fervile regard to a method founded on the number of toes, he has combined very opposite animals; the camels and the floth, the mole and the bat,
bat, the glutton and apes. Mr. Brison, in 1756, published another system, in which he has arranged animals by the number or defect of their teeth; beginning with those that are toothless, such as the ant-eater, and ending with those that have the greatest number, such as the opilion. By this arrangement, some quadrupeds, very distant from each other in their manners, are too nearly connected. We shall say nothing of Mr. Buffon’s “History of Quadrupeds,” though it contains much valuable information, because he seems to have disregarded systematic arrangement. Mr. Pennant has introduced some useful alterations in his “History of Quadrupeds,” this ingenious naturalist has followed Mr. Ray in his greater division of animals into hooved and digitated; but, after the manner of Mr. Klein, he has formed separate genera of the rhinoceros, hippopotamus, tapir, and mule. The apes are continued in the rank in which Mr. Ray placed them, and are followed by the marsupials. The carnivorous animals are arranged according to the system of Linnaeus, omitting the feal, mole, shrew, and hedge-hog. The herbivorous or frugivorous quadrupeds occupy the class assigned to them by Mr. Ray, to which he has allotted likewise the shrew, the mole, and the hedge-hog. The fourth section of digitated quadrupeds consists of those which are absolutely destitute of cutting teeth, such as the fly and armadillo. The fifth section is formed of those which are destitute of teeth of every kind, such as the manis and ant-eater. The third and fourth orders or divisions which Mr. Pennant has added, are the pinnated and the winged quadrupeds: the first comprehends the walrus, the seals, and (in conformity to preceding writers) the manatee. But he, however, observes, as the links between the quadrupeds and the cetaceous animals. The bats are winged quadrupeds, and form the next gradation from this class of birds. See Pennant’s Hist. of Quadrupeds, ed. 8vo. 1781. Preface. See Classification.

Quadrupeds, Altered. Among the many fabulous things with which natural history has been loaded, stories of flying quadrupeds seem to claim a very high rank; the gryphon, the quadruped dragon, and a great many other imaginary animals, having been introduced so largely among the descriptions of real animals, that too many have been taught to believe them. Schenchezner, in his “Physica Sacra Jobi,” has done much toward discountenancing such relations; and Hyacinthus Gemma, who has written expressly “De Fabulosis Animalibus,” has added much on the same occasion; yet all is not done. The world has late histories of lemmas and balclils, which never existed but in the imagination of the relation, or in the fanciful contrivance of the fabricator; as is evidently the case in the balclils which we find in the museums of the curious, and which are all made out of the ray-fish. And the generality of readers are so fond of any thing that is marvellous, that these things are sure to be remembered, while perhaps all the truths in the book are forgotten.

Upon the whole, the ground of the flying or alated quadrupeds seems to be properly enough reducible to this: that the words flying and alated are not synonymous terms, and that there are three kinds of flying among the quadruped clafs. The first absolute and swift, flying as perfect as in birds; this peculiarly belongs to the bat; which is the only alated or winged quadruped, properly speaking. 2. An imperfect flying by means of certain membranes serving as wings, but imperfectly, and not turning quick, or enduring long flights: such is the flying of the lizard, which is not properly an alated animal. And lastly, the imperfect flying of the squirrel kind, which even in that species called, by way of eminence, the flying squirrel, is not properly flying, but only long leaping; the creature being able to turn but very little out of a right line, and only to suspend itself during a short time in a leap from a high place to a lower. Phil. Trans. N° 247. p. 34.

Quadrupeds, in Agriculture, all such animals as walk on four legs, and are of the domestic kind, as horses, cattle, sheep, and many other forts, which are beneficial either for the purposes of working, fattening, or in any other way. Some animals of this nature are disposed for one of these purposes in preference to others; while others are capable of being used to serve more than one of them. Thus, horses of the lighter and more active kind are adapted to the faddle, and some forts of road work, and those of the more heavy fort to all descriptions of team work in the field or other places. And next cattle of the ox kind, in the left heavy breeds, as the Devonshire, Herefordshire, and some others, are well suited to team labour as well as fattening; while those of the more heavy forts, as the Lancashire breed, or long horses, &c., are better calculated for feeding only. Among sheep, some breeds are valuable for their mutton as well as their wool; some for the former, or latter, of these articles only; and others again for their ready disposition in taking on flesh. In swine, some breeds are much better formed than others; require much leafs food, in proportion to their sizes, in keeping and fattening, and are more disposed to feed, &c.

The name is likewise the cafe with some other animals of this description, which shou’d constant be taken into the account in selecting and choosing them for the use of the farmer.

Quadrupeds of all forts, shou’d also, in all cafes, be well adapted in their numbers, purposes, and kinds, to the quantities of the lands as farms, their extents, and the quantities of labour to be performed upon them, as much in the success of farming depends on this being properly done. They shou’d likewise be constantly well kept and in proper condition, according to the different intentions for which they are designed, as badly fed or half-starved animals never answer any good purpose for the farmer, they always requiring a much larger proportion of food for ref toring or bringing them again into proper order and for fattening them, than would otherwise have been necessary; and they never ultimately turn out so well, or produce so much advantage, as might have been the cafe under other circumstances. And, in labouring animals, where this is the cafe, they are never capable of performing nearly so much work, in consequence of which a vall continual los is sustained, though scarcely perceived. See Live-Stock, and Team.

Quadruplatores, among the Romans, were informers, who had the fourth part of the confiscated goods for their pains.

Quadruple, a fun or number multiplied by four, or taken four times.

Quadruple is particularly used for a gold coin, worth four times as much as that of which it is the quadruple.

The quadruple of the Spanish pittole is a piece of four pittoles, called also the double double.

The quadruple of the Louis d’or is a piece of gold coined in the reign of Louis XIII. in 1641. The legend on one side is CHRISTUS VINCI, REGNAT, IMPERAT: and on the middle of this side it has a crofs with four crowns, and can- toned in four fleurs-de-lis: on the other side it has the legend, LUDOVICUS DECIMUS TERTIUS DEI GRATIA FRANCFI- RUM REX, with the head of Louis XIII. Its value under this king was twenty livres.

Quadrupla Graecia, in French Muffs, is a note with four hooks or four ties, one degree quicker than our demi-
QUA

semiquaver, and for which we have no name. The term 
chashe, in French a quaver, is not derived from crotchet, 
but from the tail being crooked. And why our crotchet, with a 
straight tail, has its name, is a whimsical absurdity, for which 
we are unable to account.

QUE est cadem, in Pleading, is used to supply the want 
of a traverse. (2 Litt. Abr. 405.) In a clausum frigur 
such a day, the defendant pleads the plaintiff’s licence to 
him to enter on the same day, and that siveute inde he entered; 
he need not say, que est cadem transgressio.

Quae Plura, a writ that anciently lay where inquisition 
had been made by an escheator, of such lands or tenements 
as any man died seised of, and all was suppos’d not to be 
found by the officer or inquisition.

This writ was to inquire what more lands or tenements 
the parties died seised of. But it is now made ufeless, by 
taking away the courts of wards and offices post mortem.

Quae Serotina. See Per qua ferotina.

Querens non invent plagium, a return made by 
the sheriff upon a writ directed to him with this clause, 
viz. Si A. fuerit B. secum de clamoribus suos profugius, &c. 
F. N. B. 38.

Quaerernes, in Geography, a town of Norway; 55 
miles N. of Romdal.

Questa, in our Ancient Writers, denotes an indule 
gence, or remission of penance, exposed to sale by the 
popes.

Questionaril, in our Ancient Law Books, were 
people who went about with indulgences from door to door, 
defining charity either for themselves or others.

Matt. Well observes, 1240, that the king, “Terram fiam 
papale questionarios, depauperari, &c. permit.”

Questor. See Questor.

Questus, in Law, is that eflate, or those effects, 
which a man hath by acquisition or purchase; in contradif 
tion to hereditum, which is what he hath by descent. See 
Accret, and Goods.

Glauv. lib. vii. “aut habet hereditatam tantum, vel 
quaetum tantum, aut hereditatum & quaetum.”

Quaeg, in Agriculture, a name given to any fort of wet, 
swampy, morosy, or boggy situation in land, which has a 
tremulous or shaking feel under the foot, and which pro 
duces nothing but a coarse dryly herbage that is unfit for 
the food of animals. Low as well as high grounds are 
subject to spots of this kind wherever water is confined and re 
tained near the surface. They are to be removed by proper 
means of draining, and the application of solid earthy matters 
of different kinds upon the surfaces of them, with the ufe 
of rollers in order to consolidate the whole. See Bog and 
Swamp.

Quaggia, in Zoology. See Equus.

Quagliati, Paolo, in Biography, the music-master 
of the celebrated traveller, Pietro della Valle, at Rome, in 
the beginning of the 17th century. His disciple, della 
Valle, says, “that he was an excellent maestro di cappella, 
who introduced a new species of music into the Roman 
churches, not only in compositions for a fingle voice (mono 
dio), but for two, three, or four, and very often more voices, 
in chorus, ending with a numerous crowd of many choirs or 
chorusles, finging together; specimenes of which may be seen 
in many of his motets that have been since printed. And the 
music of my cari, or movable-attribute, composed 
by the same Quagliai, in my own room, chiefly in the man 
ner he found most agreeable to me, and performed in mails 
through the streets of Rome during the carnival of 1606, 
was the firtt attempt at an opéra, or peculiar drama in music, 
which had been heard in that city.” See Opera, Recap 
tative, and Pietro della Valle.

Quagmire, in Agriculture, the name of a fort of soft 
mire, or quaking bog, swamp, or muras, which is fre 
quently and commonly met with in low hollow situations, 
where there is none, or very little defent, for the discharge 
of the stagnant water or wuntis. They are formed in 
many different ways according to the nature of the cir 
cumstances those which firft gave rise to them, and that of the places 
in which they are found. The author of the “Treaty on 
Land Property” has remarked, that besides the common 
moory quagmires or bogs, there is a species which is con 
stantly charged with moifure, yet does not accumulate a 
thick covering of moory earth, owing probably, it is fur 
penced, to the want of fertility in the water by which it 
fed. These forts of quagmires are, in his opinion, for the 
moll part, found in mountainous and billy situations. Other 
kinds are occasionally seen on large peat moifes, and hollow 
meadows, in spots where the water is confined and kept 
up nearly to their upper parts, and where there is much 
decay of vegetable productions on their surfaces, and the 
reception of earthly materials from other places. These 
quagmires occupy large spots of ground in many different 
situations, and are, of course, a great los to individuals 
and the public, as little or nothing of any ufe is ever pro 
duced by them. (See Morass.) They are, for the moll 
part, capable of being readily drained by proper means, 
a fort of improvement which ought never to be negleced 
where it can be performed with any chance of success.

Quahu, in Geography, a district of Africa, on the 
Gold Coast, in the kingdom of Accamob, or Aquamboe; 
which fee.

Quahvitla, in Botany, a name ufed by fome au 
thors for the tree from which the refin commonly called gum 
copal is procured.

Quaicha, in Geography, a town of Africa, in Sen 
nar; 38 miles E.S.E. of Gieuff.

Quail, Coturnix, or Tetrao coturnix of Linnaeus, in 
Ornithology, the leaf of all the birds of the gallinaceus kind. 
They have, however, the genius of the cock kind, and may 
be bred to fight like our game cocks.

This was an old custom among the Athenians, and is still 
kept up in some parts of Italy, and in Afa.

Quails are birds of paflage, some entirely quitting our 
ifland, others shifting their quarters from one county to an 
other, and sheltering themselves among the weeds near the 
sea-fide; with us they frequent the corn-fields, and some 
times the meadows. They begin to fings in April, and make 
their nefs in the moonthe of May, building on the ground, and 
feldon lay more than six or seven whitifh eggs, 
marked with ragged nut-coloured spots.

Quails are to be taken by means of the call during their 
whole wooling time, which lafts from April to August. The 
proper times for using the call are at fun-rising, at nine 
o’clock in the morning, at three in the afternoon, and at 
fun-set; for these are the natural times of the quail’s call 
ing. The notes of the cock and hen-quail are very differen 
t, and the sportsman who expects to succeed in the taking 
of them, must be expert in both; for when the cock calls, the 
answer is to be made in the hen’s note; and when the hen 
calls, the answer is to be made in the cock’s. By this 
means they will come up to the person, fo that he may, with 
great ease, throw the net over them, and take them. If a 
cock-quail be fingle, on hearing the hen’s note he will imme 
diately come; but if he have a hen already with him, he 
will not forfake her. Sometimes, though only one quail 
answers to the call, there will three or four come up; and
and then it is best to have patience, and not run to take up the first, but lay till they are all entangled, as they will soon be.

The quail is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings they will often fly instead of running to the call; and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top, and the sportman then changing sides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather purse, about two fingers wide, and four fingers long, and made in the shape of a pear; this is to be filled half full of horsetail, and at the end of it is to be placed a small whistle, made of the bone of a rabbit's leg, or some other such bone: this is to be about two inches long, and the end formed like a flagetoe, with a little soft wax. This is to be the end fastened into the purse; the other is to be closed up with the same wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this found, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax: then the purse is to be pressed, and the finger is to shake over the middle of it, to modulate the found it gives into a fort of thack. This is the most useful call; for it imitates the note of the hen-quail, and seldom fails to bring a cock to the net, if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire, turned round and curled, and covered with leather; and one end of it must he closed up with a piece of flat wood, about the middle of which there must be a small thread or strap of leather, and at the other end is to be placed the same fort of pipe, made of bone, as is used in the other call. The noise is made by opening and closing the spiral, and gives the same found that the cock does when he gives the hen a signal that he is near her.

QUAKERS, in Ecclesiastical History, the common denomination of a society of Christians, who appeared first in England about the middle of the seventeenth century, and who continue to be distinguished from others by peculiar tenets and practices. They call themselves Friends. They are remarkable for adhering to the conveniences of the present time, of immediate revelation, or the communication of divine instruction to the mind, by the testimony of the spirit of God. This revelation they affirm to be necessary for the production of true faith, and that it neither does nor can contradict the outward testimony of the scriptures, or right and found reason. Their doctrine on this subject has been often misunderstood, even by theological writers; and they have in consequence been subjected to much obloquy. It is, however, the principal feature in that peculiar view of Christianity, which has occasioned their separation from other churches.

Origin and History.—Before the period above mentioned, many serious persons, satisfied with none of the modes of religion which the reformation brought forth, had withdrawn from the communion of every visible church, to cultivate in retirement, impressions which they attributed to the operation of the spirit of Christ in their own minds: it is chiefly from such, when brought to recognize each other by the ministry of an individual, that the Quakers consider their society to have been originally gathered. George Fox, the individual in question, was born in 1624. He has left a journal of his own life, written with a simplicity of style, which proves that he has fairly laid open his own character. In this work, the peculiar principles of Quakerism may be satisfactorily explored in their early beginnings, which it may be worth while briefly to review. Fox’s parents, who were pious members of the church of England, had intended him for the priesthood, his character affording very early promise of fitness for religious service; but others persuading to the contrary, he was put under a matter to a country business. Being engaged herein at a fair, when about the age of nineteen, a cousin of his, with another preceptor of religion, attempted to engage him in drinking to intoxication. “The Lord had shown me,” says George, “that I might not eat or drink to make myself wanton, but for health, using the creatures in their service, as servants in their places, to the glory of Him who created them.”

Accordingly, on perceiving the design of his companions, he rose up, paid for the refreshment they had had, and departed, with emotions of virtuous indignation. Returning home, he paffed a sleepless night, walking up and down, and crying to the Lord; who, he affirms, said unto him, “Thou seest how young people go together into vanity, and old people into the earth; thou must forake all, young and old, keep out of all, and be as a stranger unto all.” The reader will understand this, and generally all revelations professed to have been received by Quakers, as confounding not an outward voice, but in an internal communication to the mind. Taking the command literally, he detached himself from his connexions; and having some property of his own whereon to subsist, removed from place to place, observing the religion and professors of the age, without engaging in close fellowship with any. He devoted much of his time to fasting, solitary prayer, and reading the bible.

He became at length quite detached in his affections from the world, distilling at the spiritual condition of his fellow men, and in much anxiety, bordering on despair, about his own; yet was not without intervals of heavenly joy and comfort. Such a state of mind naturally led him to seek for spiritual counsel from others, and he had conferences with many of the clergy, beginning with his own parish priest. In answer to a question from the latter, we find him professing faith in Christ, who, by his death as man, (for he died not as he was God,) became an offering for the sins of the whole world. The general result of these conferences was, however, unsatisfactory to him: “for,” he observes, “they could not reach my condition.” Pursuing, therefore, his meditations on the subject as before, he came to be satisfied respecting several propositions which it involved, such as the following—that although it was said that all Christians are believers, both Protestants and Papists, yet that none were truly such, but those who were born of God, and who had passed from death unto life. Again, that to be bred at Oxford or Cambridge, was not enough to fit and qualify men to be ministers of Christ. At this he wondered, because it was the common belief that such qualification was sufficient. “At another time,” he says, “it was opened in me, that God, who made the world, did not dwell in temples made with hands. This at first seemed strange, because both priests and people used to call their temples or churches dreadful places, holy ground, and the temples of God; but the Lord then made me clearly that he did not dwell in those temples, which men had commanded and set up, but in people’s hearts.” George Fox now ceased to attend the established preachers; at which his relations being offended, he showed them from the scriptures, “that there was an anointing within man to teach him, and that the Lord would teach his people himself.”

Oblerving,
Obseruing, as he thought, more of the fruits of this internal teaching among the "dillenting people," he went for a while among them; but, he continues, "as I had forborne the precepts, so left the separate preachers also, and telleth called the most experienced people; for I saw there was none among them all that could speak to my condition. And when all my hopes in them, and in all men, were gone, so that I had nothing outwardly to help me, nor could tell what to do, then, O then, I heard a voice, which said, 'There is One, even Christ Jesus, that can speak to thy condition.' When I heard it my heart did leap for joy. Then the Lord let me see why there was none that could speak to my condition, namely, that I might give him all the glory. For all (he continues, alluding to Rom. xi. 32) are concluded under sin, and shut up in unbelief, as I had been, that Jesus Christ might have the pre-eminence, who enlightens and gives grace, faith, and power."

The preceding is a specimen of Fox's own account of the manner in which the doctrine he afterwards preached arose in his mind. The reader will perceive that he refers all his real edification to the means which have been already indicated, immediate revelation. He says, "though I read the scriptures, that spake of Christ, and of God, yet I knew Him not but by revelation, as he who hath the key did open, and as the Father of Life drew me to his Son by his Spirit." Yet that he was sensible of the importance of the holy scriptures, as the source from whence, under this influence, Christian instruction must be drawn, is evident, both from his declaring that they were very precious to him, and from his having incessantly used, and continually appealed to them, both before and after beginning to promulgate his system.

Having at length attained to a view of Christianity in which he found peace of mind, he believed himself required and divinely commissioned to become a teacher of it to others: and from the year 1647, the reader may conceive him always engaged in this office. He travelled as before, preaching first to small companies of enquiring persons, then to public congregations, such as upon his appearance among them were willing to hear him, and at length to large assemblies of people, convened on purpose. This he did with the courage and perseverance of a reformer; in the face of opposition from the national and dipendary preachers, of frequent personal abuse from their hearers, and occasional severe treatment by the magistrates. In most places where he came, he met with persons who received his doctrines, a proportion of whom, after associating with him for a time, became impressed with the like apprehensions of duty to propagate their principles; which they attempted by similar methods. Thus, although interrupted at different periods by imprisonment, he found himself, before many years had elapsed, in connection with a numerous band of fellow-labourers, and a widely diffused and respectable society of religious friends. No inconsiderable number of these quitted, for the sake of their principles, livings in the church, commissions in the army, or seats as magistrates.

When we consider that this happened in an age equally remarkable for religious zeal and political turbulence, it will appear that some deviations from Christian propriety, some fruits of the mixture of imagination with good intentions, could scarcely fail to be exhibited among them. If the new society, from a regard to its principle of internal impulsen to particular duties, was slow to condemn thefe, it was careful, on the other hand, not to engrat his them, by imitation on its practice. Individuals, therefore, were alone responsible for such acts, and the general conduct of the members, from the period of their first associating together, was found in no mean degree conformable to the morality of the gospel.

The most serious instance of misconduct occurred in the case of James Nayler and his followers. This fell out in 1656, and was magnified beyond its real importance by being suffered to occupy for ten days the attention of parliament. Nayler had been an Independent, and a quarter-master of horse under major-general Lambert. He was one of George Fox's earliest converts, and for some years an able preacher and disputant in the same cause. Coming to London, he found a set of people who extolled him in his office above measure. His friends, and George Fox among the rest, seeing his danger, gave him suitable cautions; but nothing he, because exposed to the flatteries of a train of followers, chiefly women, whom he suffered, at length, from a delusive notion of its being done to Christ in him, to address him with the name and titles of the Saviour, and with acts amounting to worship. In particular, his entrance into Bristol was conducted, by these intimated people, in imitation of the procession of Christ into Jerusalem. The parties implicated in this transgression were committed to prison; but Nayler alone was selected by parliament, after examination and long debates on his case, for punishment as a blasphemer. Cromwell kept aloof from the proceedings, which, by their excellent severity, moved great commotion in the public. The culprit was twice scourged through the streets, twice pilloried, branded in the forehead, and bore through the tongue with a hot iron; and all which he endured with surprising patience and fortitude.

His punishment ended with two years' close imprisonment in Bridewell, during which he attained to repentance, and a founder mind. Having given proof of this by several public confessions, the Quakers, who had disowned both him and his followers, received him back into their communion, in which he lived circumstantly the short remainder of his life.

Quakerism prevailed at first chiefly in the northern counties; but many preachers having risen up here, who travelled in different directions, it was not long in spreading to the metropolis, and the remoter southern and western parts. Wherever its professors appeared, the ordeal of suffering awaited them; for which their negative tenets commonly furnished the occasion. They refused to the priests every kind of payment, to the government military service, to the magistrates oaths, and to all persons the customary, and at that time much looked for worship, of kneeling or bowing with the head uncovered. They adhered too, in every instance, to their northern English of thou and thee, judging the plural mode of addressing one person to have originated, together with all empty titles, in a spirit of flattery unecon- theing Christians. These peculiarities were a check to superficial conversions; since an upright conformity to the profession was in most cases purchased by the loss of friends, contempt, and hardships. Even the privilege of meeting to worship, apart from the national congregations, was acquired only by persevering in the practice, through almost every kind and degree of coercive obstruction, down to the period of complete toleration, the revolution of 1688. Hence their history conflicts in great part of detail of buffettings, imprisonments, and spoiling of goods. So early as 1659 they rated to parliament, that in the preceding six years about two thousand individuals had suffered in person and estate, for being Quakers: and this representation was accompanied by one of the most extraordinary public acts on record. One hundred and sixty-four Friends offered themselves by name to the house, to be imprisoned in the places of an equal number, who from sickness or the hard-
ships of their confinement, were conceived to be in danger of perishing. The house, however, rejected this proposal, and expressed some displeasure at "the reflections on magistracy and ministry," said to be contained in the memorial. It will be proper to give some particular instances of their sufferings.

James Parish, a youth of good parts and education, going to see George Fox in a dungeon at Carlisle, became a convert to his principles: and, preaching in Ely, was the means of raising many congregations of Quakers in that county. He was imprisoned in Colchester castle, and at the age of nineteen weeks under a cruel treatment there inflicted on him. In 1658, two Quaker women arrived at Bolton, New England. They were apprehended 'ere they could land, committed to close prison, and cashiered in a brutal manner, by stripping them naked, left they might also be searched; an object to the colonists of equal and equally rational dread. These two, with eight others who arrived afterwards, were forcibly sent away: but the precaution in vain, their principles entered the colony. An aged citizen, and church member of Bolton, was first found favourably inclined to them; he was fined, imprisoned, and banished in the depth of winter. In Rhode Island he was hospitably received by an Indian chief, who offered, if he would live with him, "to make him a warm house;" observing, "What a God have the English who deal so with one another about their God!" So far is intolerance from recommending the religion of those who practice it. Penal laws against Quakers soon followed the appearance of this people in New England. The scourge was hitherto applied, without regard to age or sex: mutilation, by cutting off the ears, followed: but these being found insufficient, cruelty proceeded through another intermediate step, banishment on pain of death, to its dreadful extreme; and four Quakers were hanged at Bolton. Their names were William Robinson, Marmaduke Stevenson, William Leed, and Mary Dyer. Their cafes, as related by Sewell, in his "History of the Quakers," form an interesting piece of martyrology.

Charles II., on notice of these proceedings, granted a mandamus, which prevented further executions in the colonies; but he was not equally ready to refrain persecution at home. The Quakers had several meeting houses in London. When assembled at the, they were often dispersed by soldiers, under the direction of the magistrates; these enacted the purpose by severe beatings with their arms. One John Traveled being evidently mortally wounded in this way, a coroner's inquest was held, but the verdict of the jury was suppressed; and the king, on being informed of the facts, evaded interference, telling the complainants to prosecute the law against the folders! Similar proceedings took place at Colchester; where the congregation, being kept out of their house, met for many weeks in winter, standing in the street. Here they were assailed by folders on horseback, who wounded many of them, and a man of seventy lost his life in consequence. On one of these occasions a trooper's sword, by violent thrusting, came out of the hilt. The man he had been beating handed it up to him with these words, "I desire the Lord may not lay this day's work to thy charge." In this instance, as in others, the patience of the sufferers at length triumphed, and they were quietly allowed their right of meeting.

In 1665 a hundred and twenty Quakers were in Newgate, sentenced to transportation, under an act recently made "to prevent and suppress felonious conventicles." The matters of ships generally refusing to carry them, an embargo was laid, and it was made a condition of failing to the West Indies, that some Quakers should be taken thither by every vessel. A mercenary scoundrel being at length found for the service, the Quakers, unwilling to be active in their own banishment, refused to walk on board, as did also the farmers to hoist them in. By the help of soldiers from the Tower, fifty-five of them were at length shipped. But the matter was now in prison for debt; and the ship, after seven months' detention, quitting the coast, was immediately taken by a Dutchman, and twenty-eight of the prisoners (the remainder having died of the plague) were liberated in Holland and sent home. Other parties of Quakers were set on shore again from different vessels, so that the number actually sent to the West Indies was small.

The preceding instances may serve to show the kind of persecution which this society endured for many years; it may be observed in conclusion, that the court (or rather the clergy) of Charles, in their eagerness to suppress the growing society, actually defended to the measure of inflaming a formal order of council for demolishing their meeting-house in Southwark, which was addressed to no less a person than Christopher Wren, esq., surveyor-general of his majesty's works; but it was executed by the military, by whom the congregation, who had the courage to meet on the ruins, were dragged as often as they assembled, for nearly three months together, without however overcoming their firmness.

Though the Quakers never sent out millionaries, in the manner of some other societies, we have seen that individuals went, under apprehensions of religious duty, to distant parts. Several of these visited Italy, where they did not conceal their dislike of superstition; and one John Love, being detained at Rome on this account, died in (as it seems a violent death) in the prison of the inquisition. Catherine Evans, and Sarah Cheever, after three years' confinement, and many sufferings in the inquisition at Malta, were released and returned to England. But the most extraordinary enterprise, in this way, was performed by Mary Fisher, a maiden, and one of the two who had been ill treated at Bolton. She, apprehending she had a message from God to sustain Mahomet IV. actually made her way from England to his camp before Adrianople, where she delivered, through his interpreter, what was on her mind, was treated with respect, and offered an escort to Constantinople, which she declined, and returned, as she had gone, alone and in perfect safety. A young man, named George Robinson, went, through still greater difficulties, to Jerusalem, where, speaking against the superstition of the J ewes, he was forcibly forced into a mosque, whence the Turks, on his refusing to turn Mahometan, led him out to be put to death, as for wilfully violating the place; but a sudden change taking place in their sentiments concerning him, he also was permitted to return.

In 1666 the Quakers held their first general meeting, for the care of their poor and other concerns of the society, at Skipton in Yorkshire; within a few years after which, meetings for discipline were established throughout England and Ireland, chiefly by the incessant personal labours and epistolary recommendations of George Fox. At this period the society received a considerable accession of respectability by the conversion of William Penn and Robert Barclay. The celebrated Apology of the latter gave the world an opportunity of fairly appreciating doctrines till then but partially known, and on this account the more desired: and the settlement of the Jerseys, and subseqently, of Pennsylvania, under the auspices of Penn, opened to the Quakers a new and promising field of increase, which they did not fail speedily to occupy. Another period of con-
QUAKERS.

Considerable learning, George Keith, after associating with them for near thirty years, became the author of a MS, the circumstances of which it will be proper to notice. Keith was a native of Scotland, and educated at Aberdeen; he was imprisoned, as a Quaker, in 1664, and in 1675 ansisted Barclay in a public disputation against the students at Aberdeen; he wrote much in defence of the principles of the Quakers, which he thoroughly understood, and was employed in the education of their youth; but is thought by them to have indulged too much in curious and useless speculations, which his brethren did not encourage. Being again repeatedly imprisoned, about 1684, he removed to America in disgust. Here, after some previous general censure of his friends, he accused several, in particular, of gross error in doctrine; the pretext for which was, their holding (as he himself had done) that the knowledge and belief of the history of Christ is not necessary for the salvation of those who have no possible means of acquiring it. His complaints against individuals leading to more general contention, the Friends in England interfered, and the parties were heard before the yearly meeting in London, which decided the cause against Keith, and he remained under the "dissension" pronounced against him in America. He now set up a separate Quakers' meeting in London, attacked the principles he had formerly defended, (on which occasions the Quakers replied by quotations from his own works,) and finally entered into the church of England. He was soon after ordained priest, and made a missionary to America, to bring over his former brethren. But his efforts, though for a while troublesome to the Quakers, were attended with very little success; he returned to England, sunk into obscurity on a small living in Sussex, and his party gradually disappeared.

The jeopardy in which the Quakers almost constantly floated on account of their principles, very early introduced them to an immediate intercourse with the crown; and they thus acquired the privilege, which they still exercise, of presenting public addresses to the king, by a delegation from their body, in a manner which does not violate their conscientious scruples. The accession of a new sovereign, the conclusion of a peace, or an impending war, have commonly drawn from them addresses, in which sentiments not unworthy of their Christian profession, are conveyed in simple but respectful language. And very recently (1814), they availed themselves of the privilege in this country of the emperor of Russia, and the king of Prussia, to address each of these monarchs in favour of a perfect toleration in their respective dominions; in which they met with a favourable reception. Another great and interesting object, the abolition of the slave trade, has frequently brought them forward to government in this way. In the cause of humanity, as it regards the oppressed Africans, they have proved themselves strenuous and indefatigable: the reproach, even of holding a fellow man in slavery, was wiped away from the members of this society many years before the abolition of the trade was decreed, either in England or America. This was effected by their discipline; and it was made a part of this, in consequence of that view of Christianity, which regards every individual of the human race as a fit object of its benefits, and as entitled to the charitable regard which it inculcates. Much was done on the Negroes' behalf, in America, by Anthony Benezet, whose character is well known to the world; and by John Woolman, a minister of the society, whose writings discover a mind of uncommon purity, simplicity, and tenderness.

The Quakers as a body have been long relieved from actual perfection: yet they are still involved by their principles in occasional trouble as individuals. The refusal to bear arms, or to pay military fines, subjects them to legal disfratment on their goods, and if none of these be found, to imprisonment. Tithes and other ecclesiastical claims, enforced upon them, likewise render disfratment a very common, and sometimes an oppressive occurrence; and if the prosecutor be more rigorous, they may be imprisoned for an indefinite time. It is obvious that, refusing to swear, they cannot fill any office of profit or trust under government. Except for these purposes however, for serving on juries, and in cases of criminal prosecution, their solemn affirmation before the magistrate has the legal force of an oath.

The Quakers are dispersed over the united kingdom, and most of the states of North America; from the southern states of the latter they have mostly emigrated of late to the Ohio. In America they are chiefly engaged in agriculture; and for a series of years have been making judicious and successful efforts to introduce this, with the other arts, and the manners of civilized life, among the Indian natives. There are a few Quakers in Germany, and their principles are entertained by some persons in France.

In this country they are found chiefly in the middle classes of citizens, and in trade or manufacture. Their general delirium of agriculture seems to have resulted from the impediments offered by the tithing system: a yoke which, under their feruple, becomes doubly heavy on the farmer. There is a greater approach to equality in the civil condition of the Quakers, than obtains in almost any other body: the children of such as become very rich are apt to quit the society, either by marrying persons not in its communion, or for the sake of liberties which it prohibits: and the children of the poor commonly get a plain but solid education, superior to their condition, by means of which they rise in civil society to a higher level. They have several excellent establishments for this purpose: the principal of which, situated at Ackworth in Yorkshire, contains, of both sexes, three hundred children, and was founded in 1778, at the instance of Dr. Fothergill. With provision for mathematical and classical learning, the Quakers, though they have some good private schools, are but slenderly furnished; and they have in consequence few accomplished men in these branches. They are by no means deficient in general information, and of late years many of them have cultivated natural philosophy with success. The society in its earlier stage, including many men of regular scholastic education, who had joined it on principle, had of course the advantage, in point of theological knowledge, over the modern Friends, who chiefly inherit their profession, and whose education has but of late begun to include systematic instruction in the doctrines of Christianity to large.

In morals they are allowed to excel: their youth is watched over in this respect with more than ordinary care; and when grown up, their discipline prohibits, to all conditions, these amusements which offer to the mind the ready means of dissipating serious impressions. Habitual offenders against their peculiar regulations forfeit their membership, as well as those who violate the more obvious rules of justice and morality: their moral character, and consistency as a body, are thus kept up. But it is alleged, that they are not equally well guarded against a money-getting spirit, which is apt to grow upon those who intently prosecute trade and commerce to the exclusion of all other pursuits. From the occasional tenor of the society's advices to its members, it should seem that this is in a certain degree true; and that it behoves...
behaves them to seek for an adequate remedy. They are not, however, chargeable with the love of money for its own sake; no chief of men being more beneficent, or more prompt to contribute their time and subsistence to various public institutions, which the spirit of the Christian religion has at length raised up, for relieving the distressed, promoting the comforts, and improving the moral and religious condition of mankind.

As to the minuter features of their character, the Quakers are prudent and methodical in their business generally good economists of time and money. Their conversation has many peculiarities; some of which flow from their principles, others merely from their associating chiefly among themselves. They were early thought to be habitually crafty ("the Quaker fly," says Pope); but there seems no other ground for this, than the extreme caution with which they incur engagements, or make professions and promises. Viewed at a distance, they appear cold, formal, and reserved in their manners; and have hence been unjustly concluded void of domestic cheerfulness, and incapable of the enjoyments arising from social converse, and the intercourse of cultivated minds. They are plain in their dress; the peculiarities observable in which result, not from any regulations on the subject, but from an indigitation to vary with the fashion; they have, however, slowly followed changes which have proved general and permanent, and thus become less conspicuously singular. Mourning habits they reject on principle: and with a people whose ordinary dress is so grave, the moral reason for them seems not to exist. They are averse to splendour in furniture and equipage: though the rich among them, in these articles, and most of their females in dress, have contrived, without ceasing to be known as Quakers, to refine considerably upon absolute simplicity.

** Doctrine. — A recent publication on behalf of the society, entitled, “A Summary of the History, Doctrine, and Discipline of Friends,” ascribed to one of the society, held in high estimation, viz. Mr. J. G. Bevan, who died whilst this article was in the press, states their doctrine as follows:—

"We agree with other professors of the Christian name, in the belief of one eternal God, the creator and preserver of the universe; and in Jesus Christ, his Son, the Messiah, and mediator of the new covenant.

"When we speak of the gracious display of the love of God to mankind, in the miraculous conception, birth, life, miracles, death, resurrection, and ascension of our Saviour, we prefer the use of such terms as we find in scripture; and contented with that knowledge, which divine wisdom hath been meet to reveal, we attempt not to explain those mysteries which remain under the veil; nevertheless we acknowledge and affect the divinity of Christ, who is the wisdom and power of God unto salvation."

"To Christ alone we give the title of the Word of God, and not to the scriptures, although we highly esteem these sacred writings, in subordination to the Spirit from which they were given forth; and we hold with the apostle Paul, that they are able to make wise unto salvation, through faith which is in Christ Jesus."

"We revere those most excellent precepts, which are recorded in scripture to have been delivered by our great Lord, and firmly believe that they are practicable and binding on every Christian; and that in the life to come every man will be rewarded according to his works. And further, it is our belief, that, in order to enable mankind to put in practice these sacred precepts, many of which are contradictory to the unregenerate will of man, every man coming into the world, is endowed with a measure of the light, grace, or good Spirit of Christ; by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his fallen nature, which mere reason is altogether insufficient to overcome. For all that belongs to man is fallible, and within the reach of temptation; but this divine grace, which comes by Him, who hath overcome the world, is, to those who humbly and sincerely seek it, an all-sufficient and present help in time of need. By this, the snares of the enemy are detected, his allurements avoided, and deliverance is experienced through faith in its effectual operation: whereby the soul is translated out of the kingdom of darkness, and from under the power of Satan, into the marvellous light and kingdom of the Son of God."

"Being thus persuaded that man, without the spirit of Christ inwardly revealed, can do nothing to the glory of God, or to effect his own salvation; we think this influence especially necessary to the performance of the highest act of which the human mind is capable; even the worship of the Father of lights and of spirits, in spirit and in truth: therefore we consider the instructions to pure worship, all forms which divert the attention of the mind from the secret influence of this mission from the Holy One. Yet, although true worship is not confined to time and place, we think it incumbent on Christians to meet together, in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength; thus, 'Every not only partakes of the particular refreshment and strength which comes from the good in himself, but is a闪耀 of the whole body, as being a living member of the body, having a joint fellowship and communion with all.' "Barclay.

"Nevertheless, in the performance of worship, we dare not depend, for our acceptance, on a formal repetition of the words and experiences of others; but we believe it to be our duty to lay aside the activity of the imagination, and to wait in silence to have a true light of our condition bestowed upon us; believing even a single sight, arising from such a sense of our infirmities, and of the need we have of divine help, to be more acceptable to God, than any performances, however specious, which originate in the will of man. If any should object the difficulty of laying aside the activity of the imagination, let such consider the following statement—That it is our duty to maintain a watch over our thoughts, by endeavouring to preserve our attention from being carried away by such as manfully originate in our own natural will or habits, and to wait patiently for the arising of the life of Christ; which by bringing every thought into subjection, produces a true inward silence, and therein affords a true sense of our condition."

"From what has been said respecting worship, it follows that the ministers we approve must have its origin from the same source; for that which is needful for a man's own direction, and for his acceptance with God, must be eminently to enable him to be helpful to others. Accordingly we believe, that the renewed influence of the light and power of Christ is indispensably necessary for all true ministry; and that this holy influence is not at our command, or to be procured by study, but is the free gift of God to chosen and devoted servants. Hence arises our testimony against preaching for hire, in contradiction to Christ's positive command, 'Freely ye have received, freely give;' and hence our conscientious refusal to support such ministry, by titles or other means."

"As we dare not encourage any ministry, but that which we believe to spring from the influence of the Holy Spirit, so neither dare we attempt to reclaim this ministry to persons of any condition in life, or to the male sex alone; but,
as male and female are one in Christ, we hold it proper that such of the female sex as we believe to be endued with a right qualification for the ministry, should exercise their gifts for the general edification of the church; and this liberty we esteem a peculiar mark of the gospel dispensation, as foretold by the prophet Joel, and noticed by the apostle Peter.

"Three are two ceremonies in use among most professors of the Christian name, water-baptism, and what is termed the Lord’s supper. The first of these is generally esteemed the essential means of initiation into the church of Christ; and the latter, of maintaining communion with him. But as we have been convinced that nothing short of his redeeming power, inwardly revealed, can set the soul free from the thraldom of sin; because this power alone we believe salvation to be effectual. We hold that as there is one Lord and one faith, so his baptism is one, in nature and operation; that nothing short of it can make us living members of his mystical body; and that the baptism with water, administered by his forerunner John, belonged, as the latter confessed, to an inferior and decreasing dispensation.

"With respect to the other rite, we believe that communion between Christ and his church is not maintained by that, or by any other external performance, but only by a real participation of his divine nature through faith; that is, the supper alluded to in the Revelation. ‘Behold I stand at the door and knock: if any man hear my voice, and open the door, I will come in to him, and will sup with him, and he with me,’ and that where the substance is attained, it is unnecessary to attend to the shadow; which doth not confer grace, and concerning which, opinions so different, and animosities so violent, have arisen.

"Now, as we thus believe that the grace of God, which comes by Jesus Christ, is alone sufficient for salvation, we can neither admit that it is conferred on a few only, whilst others are left without it; nor, thus afflicting its universality, can we limit its operation to a partial cleansing of the soul from sin, even in this life. We entertain worthier notions both of the power and goodness of our heavenly Father, and believe that he doth vouchsafe to all the obedient to experience a total surrender of the natural will, to the guidance of his pure unerring Spirit; through whose renewed assistance they are enabled to bring forth fruits unto holiness, and to stand perfect in their present rank.

"There are not many of our tenets more generally known than our testimony against oaths, and against war. With respect to the former of these, we abide literally by Christ’s positive injunction, delivered in his sermon on the mount, ‘Swear not at all.’ From the same sacred collection of the most excellent precepts of moral and religious duty, from the example of our Lord himself, and from the corresponding convictions of his Spirit in our hearts, we are confirmed in the belief that wars and fightings are, in their origin and effects, utterly repugnant to the gospel; which still breathes peace and goodwill to men. We also are clearly of the judgment, that if the benevolence of the gospel were generally prevalent in the minds of men, it would effectually prevent them from oppressing, much more from enslaving, their brethren (of whatever colour or complexion), for whom, as for themselves, Christ died; and would even influence their conduct in their treatment of the brute creation, which would no longer groan, the victims of their avarice, or of their false ideas of pleasure.

"Some of our tenets have in former times, as hath been shewn, subjected our Friends to much suffering from government; though to the faithful professors of government, our principles are a security. They incalcula sublimation to the laws, in all cases whereon conscience is not violated. But

"We hold, that as Christ’s kingdom is not of this world, it is not the business of the civil magistrate to interfere in matters of religion, but to maintain the external peace and good order of the community. We therefore think perfection, even in the smallest degree, unattainable. We are careful in requiring our members not to be concerned in illicit trade, nor in any manner to defraud the revenue.

"It is well known that the society, from its first appearance, has diffused those names of the months and days, which having been given in honour of the heroes or false gods of the heathens, originated in their sluttish or superstitious; and also the custom of speaking to a single person in the plural number, as having likewise arisen from motives of adulation. Compliments, superfluity of apparel, of furniture, and of provision for the table, outward shows of rejoicing and mourning, and the observation of days and times, we esteem to be incompatible with the simplicity of a Christian life; and public diversions, gaming, and other vain amusements of the world, we cannot but condemn. They are a waste of that time which is given us for nobler purpotes; and divert the attention of the mind from the sober duties of life, and from the reproofs of instruction, by which we are guided to an everlasting inheritance.

"To conclude, although we have exhibited the several tenets which distinguish our religious society, as objects of our belief; yet we are sensible that a true and living faith is not produced in the mind of man by his own effort; but is the free gift of God in Christ Jesus, nourished and increased by the progressive operation of his Spirit in our hearts, and our proportionate obedience. Therefore, although for the preservation of the testimonies given us to bear, and for the peace and good order of the society, we deem it necessary that those who are admitted into membership with us, should be previously convinced of those doctrines which we esteem essential; yet we require no formal subscription to any articles, either as a condition of membership, or a qualification for the service of the church. We prefer judging of men by their fruits, and depending on the aid of Him, who, by his prophet, hath promised to be ‘for a spirit of judgment to him that setteth in judgment.’ Without this, there is a danger of receiving numbers into outward communion, without any addition to that spiritual sheath-fold, whereof our blest Lord declared himself to be both the door and the shepherd; that is, such as know his voice, and follow him in the paths of obedience.

"To this statement may be added the following extracts, the first of which is from a declaration signed on behalf of the society in 1693.

"We sincerely profess faith in God by his only-begotten Son Jesus Christ, as being our light and life, our only way to the Father, and also our only Mediator and Advocate with the Father;—that God created all things, he made the worlds, by his Son Jesus Christ, he being that powerful and living Word of God by whom all things were made; and that the Father, the Word, and the Holy Spirit, are One, in divine Being inexpressible; One true, living, and eternal God blessed for ever;—yet that this Word or Son of God, in the fulness of time, took flesh, became perfect Man, according to the flesh descended and came of the seed of Abraham and David, but was miraculously conceived by the Holy Ghost, and born of the Virgin Mary, and also, farther, declared powerfully to be the Son of God, according to the Spirit of sanctification, by the resurrection from the dead;—that, as Man, Christ died for our sins, rose again, and was received up into glory in the heavens; he having, in his dying for all, been that one, great, universal offering and sacrifice for peace, stonement, and reconciliation between God and man; and he is the propitiation.
The doctrine of the resurrection of the dead is so connected with the Christian religion, that it will be also proper to say something on this subject. In explaining our belief of this doctrine, we refer to 15th chapter of the Epistle to the Corinthians. It is clearly laid down the resurrection of a body, though not of the same body that dies. Here we rest our belief in this 'mystery,' without defining to pay it beyond what is revealed to us; remembering that 'secret things belong unto the Lord our God, but those things which are revealed belong unto us and to our children,' Principles of Religion, as professed by the Quakers, by Henry Tuke.

Discipline: from the 'Summary,' with some abridgment. 'The purposes which our discipline hath chiefly in view, are, the relief of the poor, the maintenance of good order, the support of the testimonies which we believe it is our duty to bear to the world, and the help and recovery of such as are overtaken in faults: in a few words, the promotion of piety and charity.

In the practice of discipline, we think it indefinable that the order recommended by Christ himself be invariably observed. 'If thy brother shall trespass against thee, go and tell him his fault between thee and him alone; if he shall hear thee, thou hast gained thy brother; but if he will not hear thee, then take with thee one or two more, that in the mouth of two or three witnesses, every word may be established; and if he shall neglect to hear them, tell it unto the church.'

To effect the salutary purposes of discipline, meetings were appointed, at an early period of the society, from the times of their being held, were called quarterly meetings. It was afterwards found expedient to divide the districts of these meetings, and to meet more frequently; from whence arose monthly meetings, subordinate to those held quarterly. At length, in 1665, a Yearly Meeting was established, to superintend, arbitrate, and provide rules for the whole: previously to which, general meetings had been occasionally held.

A monthly meeting is usually composed of several particular congregations, situated within a convenient distance from each other. Its business is to provide for the subsistence of the poor, and for the education of their offspring; to judge of the sincerity and fitness of persons appearing to be convinced of the religious principles of the society, and desirous to be admitted into membership; to excite due attention to the discharge of religious and moral duty; and to deal with disorderly members. Monthly meetings also grant to such of their members as remove into other monthly meetings, certificates of their membership and conduct, without which they cannot gain membership in such meetings. Each monthly meeting is required to appoint certain persons, under the name of overseers, who are to take care that the rules of their discipline be put in practice; and when any case of complaint, or disorderly conduct, comes to their knowledge, to see that private admonition, agreeably to the gospel rule before mentioned, be given, previously to its being laid before the monthly meeting.

When a case is introduced, it is usual for a small committee to be appointed, to visit the offender, to endeavour to convince him of his error, and to induce him to forsake and condemn it. If they succeed, the person is by minute declared to have made satisfaction for the offence; if not, he is disown as a member of the society.

In disputes between individuals, it has long been the decided judgment of the society, that its members should not sue each other at law. It therefore enjoins all to end their differences by speedy and impartial arbitration, agreeably to rules laid down. If any refuse to adopt this mode, or, having adopted it, to submit to the award, it is the direction of the yearly meeting that such be disowned.

To monthly meetings also belong the allowing of marriages; for our society hath always contended to acknowledge the exclusive authority of the priests in the solemnization of marriage. Those who intend to marry, appear together, and propose their intention to the monthly meeting; and if not attended by their parents or guardians, produce a written certificate of their consent, signed in the presence of witnesses. The meeting then appoints a committee to inquire whether they be clear of other engagements respecting marriage; and if, at a subsequent meeting, no objections be reported, they have the meeting's consent to solemnize their intended marriage. This is done in a public meeting for worship, towards the close whereof the parties stand up, and solemnly take each other for husband and wife. A certificate of the proceedings is then publicly read, and signed by the parties, and afterwards by the relations, and others as witnesses. Of such marriages the monthly meeting keeps a record; as also of the births and burials of its members. A certificate of the date, of the name of the infant, and of its parents, signed by the present at the birth, is the subject of one of the last mentioned records; and an order for the interment, countersigned by the grave-maker, of the other. The naming of children is without ceremony. Burials are also conducted in a simple manner. The body, followed by the relations and friends, is sometimes, previously to interment, carried to a meeting; and at the grave a paean is generally made; on both which occasions it frequently falls out, that one or more friends present have somewhat to express for the edification of those who attend; but no religious rite is considered as an essential part of burial.

Several monthly meetings compose a quarterly meeting. At the quarterly meeting are produced written answers from the monthly meetings, to certain queries respecting the conduct of their members, and the meeting's care over them. The answers thus received, are digested into one, which is sent, also in the form of answers to queries, by representatives, to the yearly meeting. Appeals from the judgment of monthly meetings are brought to the quarterly meetings; whose business also it is to adjudge in any difficult case, or where remittances appear in the care of the monthly meetings over the individuals who compose them.

The yearly meeting has the general superintendence of the society in the country in which it is established; and therefore, as the accounts which it receives discove the state of inferior meetings, as particular exigencies require, or as the meeting is impelled with a sense of duty, it gives forth its advice, makes such regulations as appear to be requisite, or excites to the observance of those already made; and sometimes appoints committees to visit those quarterly meetings which appear to be in need of immediate advice. Appeals from the judgment of quarterly meetings are here finally determined, and a brotherly correspondence, by epistles, is maintained with other yearly meetings.

QUAKER.

In this place it is proper to add, that, as we believe women may be rightly called to the work of the ministry, we also think that to them belongs a share in the support of our Christian discipline; and that some parts of it wherein their own sex is concerned, devolve on them with peculiar propriety. Accordingly they have monthly, quarterly, and yearly meetings of their own sex, held at the same time with those of the men; but separately, and without the power of making rules.

In order that those who are in the situation of ministers may have the tender sympathy and counsel of those of either sex, who, by their experience in the work of religion, are qualified for that service, the monthly meetings are advised to select such, under the direction of elders. These, and ministers approved by their monthly meetings, have meetings peculiar to themselves, called meetings of ministers and elders; in which they have an opportunity of encouraging each other to a discharge of their several duties, and of extending advice to those who may appear to be weak, without any need of exposure. Such, it may be here observed, as believe themselves required to speak in meetings for worship, are not immediately acknowledged as ministers by their monthly meetings; but time is taken for judgment, that the meeting may be satisfied of their call and qualification. It will also sometimes happen, that such as are not approved will obtrude themselves as ministers, to the grief of their brethren; but much forbearance is used towards those, before the disapprobation of the meeting is publicly testified. These meetings of ministers and elders are generally held in the churches of each monthly, quarterly, and yearly meeting. They are conducted by rules preferred by the yearly meeting, and have no authority to make any alteration or addition to them. The members of them unite with their brethren in the meetings for discipline, and are equally accountable to the latter for their conduct.

It is to a meeting of this kind in London, called the second-day's morning meeting, that the revival of manuscripts concerning our principles, previous to publication, is intrusted by the yearly meeting held in London; and also the granting, in the intervals of the yearly meeting, of certificates of approbation to such ministers as are concerned to travel in the work of the ministry in foreign parts; in addition to those granted by their monthly and quarterly meetings.

The yearly meeting of London, in the year 1675, appointed a meeting to be held in that city, for the purpose of advising and affilling in cafes of suffering for conscience-sake, which hath continued with great use to the society to this day. It is composed of friends under the name of correspondents, chosen by the several quarterly meetings, and who reside in or near the city. The same meetings also appoint members of their own in the country as correspondents, who are to join their brethren in London on emergency. The names of all these correspondents, previously to their being recorded, are forwarded to the approbation of the yearly meeting. Such men as are approved ministers are also members of this meeting, which is called the Meeting for Sufferings; a name arising from its original purpose, and which is not yet become entirely obsolete.

The yearly meeting has intrusted the meeting for sufferings with the care of printing and distributing books, and with the management of its flock; and, considered as a flandering committee of the yearly meeting, it hath a general care of whatever may arise, during the intervals of that meeting, affecting the society, and requiring immediate attention: particularly of those circumstances which may occasion an application to government. The flocks of the yearly meeting, just mentioned, is an occasional voluntary contribution, expended in printing books,—salary of a clerk for keeping records,—the passage of ministers who visit their brethren beyond seas,—and some small incidental charges: but not, as has been falsely suppos'd, the reimbursement of those who suffer distress for titles and other demands with which they scruple to comply. G. Fox's Journal. Sewell's History of the Quakers. Gough's History of the Quakers. Bear's Sufferings of the Quakers. Barclay's Apology. Clarkson's Portrait of Quakerism.

The editor is indebted for the historical part of the preceding article to a respectable member of the society of Friends. Mr. Clarkson's work, which was composed in conseqence of his intimate personal acquaintance with many of its leading members, produced by his labours for the abolition of the slave trade, may be consulted for a more ample account of the manners, practices, and opinions of this society.

QUAKER-TOWN, in Geography, a post-town of America, in Bucks county, Pennsylvania; 18 miles from Washington.

QUAKING-Bog, in Agriculture, a name usually given to a sort of soft pulpy, flexible, earthy depositions, which are formed in hollow moist situations, in conseqence of the stagnation of water in them in some manner or other. Bog of this kind differs much in their nature, qualities, and properties, according to the difference of circumstances and situations, but they have all a tremulous motion under the foot, when capable of being trodden upon. See Bog and Quagmire.

Draining is here equally necessary, as in all other cases of a similar kind, and may modestly be carried into execution without any great difficulty.

QUAKING-GRAF, in Botany, so called from the trembling of the pendulous spikelets, occasioned by their capillary zigzag stalks. See BRIZA.

QUAKING-GRAF, in Agriculture, the common name of a sort of grass, which is laid to thrive and flourish well on most kinds of poor cold land, and which cattle eat in a greedy manner; but which is not much adopted for cultivation in grassy grounds, though it makes tolerably good hay. See BRIZA.

QUAKU, or QUAKA, in Geography, a district of Africa, on the Gold Coast.

QUALATCHE, a town of the ilate of Georgia; 10 miles W. N. W. of Tugalo.

QUALE jus, in Law, was an ancient writ judicial, which lay where a religious person had judgment to recover land; before execution was made of the judgment. This writ was sufled forth to the executor between judgment and execution, to enquire whether the religious person had right to recover, or whether the judgment were obtained by collusion between the demandant and tenant; to the intent that the true lord might not be defrauded.

QUALEA, in Botany, a Caribean name, used by Aubl., and inaptly adopted by Schreber; possibly because, as it appears, he suspected the genus not to be sufficiently distinct from Vechy of the same author, his own CYCULARIA; see that article. Willdenow, however, has followed him; and thus one name more is added to dunghill, which some future botanical Hercules must sweep away. — Aubl. Gên. v. 1.5. Schreb. 7 Willd. Sp. Pl. v. 1.18. Mart. Mill. Dict. v. 4. Jull. 424. Lamarck Illustr. t. 4. —Cliffs and order, Monandria Mongenysia. Nat. Ord. perhaps Guttiferae, Jull.

Gen. Ch. Cal. Perianthus inferior, of one leaf, in four very deep ovate, coriaceous, concave, unequal segments; the two lowermost largest, spreading widely. Cor. Petals two, unequal, inserted into the calyx; the uppermost erect, roundish, emarginated, terminating at the base behind, in a short, obtuse, horn-like nectary, projecting between the upper leg.

Obst. The corolla is, as it were, two-lipped. This genus is akin to Cucularia. Schreb. Eff. Ch. Calyx inferior, in four deep unequal segments.

Petal two, unequal. Berry? with many seeds.

1. Q. rufa. Aubl. Guian. t. 1. Willd. v. 1. — Lower petal indented. Leaves elongated at the point. — Native of the wood of Guiana, flowering in September. The inhabitants call this species Labutta. A tree, whose trunk is five feet or more in height, terminating in large spreading branches. Wood red, compact. Leaves opposite, in pairs crossing each other, on short filial stalks, elliptical, three or four inches long, entire, smooth, with an elongated blunt point; their transverse veins very numerous, straight and parallel. Stipula deciduous. Panicles terminal. Flowers numerous, two inches long, powerfully and agreeably scented, white on the outside, rosel-coloured, and finally yellowish, within.

2. Q. carules. Aubl. Guian. t. 2. Willd. n. 2. — Petals two-lobed. Leaves with a short point. — Native of the Guiana forests. This species flowers in October, and is known by the name of Qua. It differs from the former in having smaller flowers, of a grey or blueish colour, but fragrant like those of Q. rufa. Their petals are emarginate, or almost obsolete. Points of the leaves less elongated.

QUALIFICATION for killing game, for jurors, justices, members of parliament, and electors of members. See Game, Jury, Justices, and Parliament.

Qualifications for a complete musician, required by Zarlingo. This venerable theorist had very exalted ideas of a perfect musician, and tells us (Instit. vol. ii. part iv. p. 542, et seq.) that it is necessary he should have a knowledge in arithmetic, for the calculation of musical proportions; of geometry, to measure them; of the monochord and harmonicon, to try experiments and effects; that he should be able to tune instruments; in order to accustom the ear to diffinguit and judge of intervals; that he should learn with truth and taste, and perfectly understand counterpoint; that he should be a grammarian, in order to write correctly, and set words with propriety; that he should read history, to know the progress of his art; be a master of logic, to reason upon, and investigate the more abstruse parts of it; and of rhetoric, to express his thoughts with precision; and, further, that he would do well to add to these sciences acquaintance with natural philosophy, and the philosophy of sound; that his ears being perfectly exercised and purified, may not be easily deceived. And adds, that he who aspires at the title of perfect musician, has occasion for all these qualifications, as a deficiency in any one of them will frequently render the rest useless. An additional qualification is now become necessary to be added to these enumerated by Zarlingo, which is a perfect knowledge of the genius and powers of all the instruments for which a musician writes; otherwise he will not only embarrass a performer by useless and unnecessary difficulties, but lose opportunities of producing effects by the bow of a violin, the coup de langue of flutes, and a selection of the purest and softest tones on other wind instruments.

Qualifications of Land-managers, &c. the requisite requirements which are proper and essential to them in order to the due and full performance of all the different sorts of business in which they may be engaged or employed. In this view, a considerable knowledge of the principles and practices of different sorts of farming and farm-management, fame acquaintance and experience in surveying land, in mechanics, in rural architecture, and in the businefs of planting; are indispensably necessary, as well as a notion of the various mineral and other substances contained in the bowels of the earth, and a ready facility in arranging the management of different sorts of accounts.

They should at the same time possess mild, conciliatory dispositions, exact upright principles, and strict moral character. See Land-Recever, Land-Steward, and Office of Bailiff.

The duties and uses of these sorts of managers, besides those of regulating and directing the husbandry, management, and other matters, are, the preventing all sorts of encroachments from taking place; the seeing that a proper and right method of flocking is pursued on the commonable lands; the guarding against the turf or foil being injured by being broken up or pared off; the looking after the public and private roads, lanes, and driveways, to see that the fences on the sides of them are properly cut and pruned as occasion may require, the travelable parts of them kept free from obstructions; and in a suitable state of repair; and that the farm-ways are well calculated to the uses and intentions for which they were designed; the duly attending to the open drains, water courses, and common waters, to take care that they are kept clear and free at all times, without doing injury to any one; the considering the state of the natural streams and running waters as fit for the purposes of watering live stock at home or in other places, those of irrigating land, the turning of mills, &c.; the examining the borders of rivers, brooks, &c. to see that they are not carried away, or their courses altered in any injurious manner: the taking care of plantations, and all sorts of woodlands, as well as timber-trees and young plants, by seeing that they are preferred in a proper manner; no damages committed by cutting them down, or in any other ways; the attending to the situation of the fences, gateways, &c. to see that the live hedges, with their banks, be duly cut, weeded, pruned, and kept up, as well as the gates, files, pairs, and other dead fences properly preferred and in repair; the keeping the home buildings, farm cottages, and garden grounds, belonging to them, in proper condition, with their tenants in a full state of industry; and lastly, the regulating the order of the different occupiers, by preventing improper meetings of all kinds, the reprimand of bad houses, and all sorts of irregularities that have a tendency to lessen industry and frugality.

Besides these, there are many other duties which properly belong to them, but which need not be mentioned in this place. See Bailiff.

Qualifications of Tenants, the necessary properties and circumstances which render them fit for holding lands as farms. The importance of having persons perfectly qualified as tenants, is very great, in the superintendence and management of all landed property, being, in a great measure, the basis, or principal bearing, on which its uniform and lasting prosperity depends.

The proper qualifications of a good tenant, according to the author of the "Treatise on Landed Property," are the having capital, skill, industry, and character. And he contends, that without a sufficient capital, the rent is unavailing; but that, at the same time, an industrious, frugal, good farmer will thrive with difficulties, and get on with less money than a man of contrary qualifications. But if he has not sufficient strength to work his lands, nor a sufficiency of live-stock to raise manure, or money whereby to purchase it, he must, under ordinary circumstances, live in a state of poverty and hard labour; and, on the first attack of misfortunes, or the first failing season of crops, he will probably fail.
fink under the weight of his accumulated burden, and be ruined.

Further, that in regard to the proper ratio or proportion between the rent and capital, it depends on the existing state and circumstances of the farms, and the style of management in which they are intended to be conducted; as well as on the number and strength of the occupiers’ families, and their industry and frugality. However, in order to afford some general notions on the matter, it may be said that, for farms of size, as those of from one to five hundred pounds a year, the occupiers should have at their commands from five hundred to a thousand pounds of capital, for every hundred pounds of rent which they may pay. Yet still, on the greater number of farms, the first proportion is too small to manage them with full advantage and profit. And, if they be farmed without spirit, and the higher order of improvements be attempted, particularly the introduction of the best breeds of live-stocks adopted by modern farmers, the lack will not be found too large for the purpose.

It may be remarked, that it is constantly the best way for tenants to farm somewhat within their capitals, as a few pounds kept in their pockets enables them to embrace and take the advantage of every favourable opportunity that may offer, and to fell or buy with the greatest benefit. While such as are straightened for money, are forced to take the chance of markets, and liable to make bargains of a loosing and disadvantageous nature, as well as experience many other inconveniences of different kinds.

Notwithstanding, where there is a want of sufficient experience and skill in the art, and different branches of practical husbandry, tenants cannot farm or manage their lands with the most profit, either to themselves, or the proprietors of them. Where, however, their capitals and exertions are great, they may, by observation and practice, acquire skill; and by this means be enabled to perform the business in a tolerable manner, and in some measure do justice to their farms, whatever they may do for their families in the way of getting money for their benefit. But where, with a want of skill, scanty capitals are joined, it is not all the exertion, industry, and frugality in the power of man, that can save or preserve the families or the farms from injury and inconvenience.

However, without industry, capital and skill may be said to be thrown away. In the management of rural business, in which so much depends on the fortune of seasons and weather, idleness is a vice of the darkest cast. Every instance of negligence is not only injurious in itself, but operates as a dangerous and bad example; serving as an apology or excuse for the half industrious, with whom every farm or estate is incubered in a greater or lesser degree.

In consequence of the intimate connection which necessarily subsists between the proprietors and the occupiers of land, and seeing how advantageous and profitable it is to prefer good order and regularity upon farm lands, as giving thereby full liberty and freedom to the exertions of their tenancy, it becomes a matter of some importance, in the selection of farm-tenants, to make proper and necessary inquiries into their characters for morality, and particularly as they relate to habits of sobriety or extravagance, as well as to a peacefulness or quarrelsome disposition.

And it is farther to be remarked, in respect to the proper selecting of tenants for farms, that nothing of interest, or any other consideration whatever, that is not intimately connected with the above qualifications, can properly warrant the choice; unless in particular cases and circumstances, as in providing for the widows and orphans of deceased tenants, &c. A farm-manager should not forfeit himself to be influenced by any sort of family connection, favour, fear, or reward. Superintendents of this kind, merely as such, cannot have any true interests separate and distinct from those of the farms or lands they may overlook. It, therefore, becomes a dithemial act in any agent of this sort, to put an inferior tenant into the possession of a farm, through his own interest, even at a fair rent for the farm.

Lastly, it may be noticed, that in a district which stands forward in a prominent manner in the ranks of rural improvements, merit should be looked for and encouraged near home. But to advance or bring up a farm or estate which remains in the rear of modern practices, two or more tenants of the higher classes should be sought for, at a distance, in such districts as are of a kindred nature, but in which the more modern and profitable management of farming prevails, in order to lead and direct the native tenantry of the situation.

There are some of the principal and leading qualifications which ought in all cases to direct and regulate the choice of farm-tenants; there are, however, many others which should have an influence in certain circumstances, and particular methods of farm-management, otherwise the full interests and advantages of the proprietors of the lands may be overlooked and neglected.

QUALIFICATOR, in the Canon Law, a divine appointed to qualify, or declare the quality of, a proposition brought before an ecclesiastical tribunal; chiefly before the inquisition.

The qualificators of the office are not judges; they only give their sentiments on the propositions presented to them. They are the inquisitors that judge.

QUALITY, Qualitas, that affection of a thing, whence it is denominated such; or that which occasions a thing to affect our fancies in this or that manner, and gives it this or that denomination. Accordingly quality is said to be an attribute, from which no futility is exempt. See More.

Thus, that power in fire, whatever it be, by which it excites in us the sensation of heat, since it is that whence the fire is denominated hot, is called the quality of fire.

The word quality, qualitas, is said to have been first introduced into the Latin by Cicero; till his time the Romans studiously avoided using a term which denoted an abstract; and in the case of it only considered concrete, signified by quale. The like is observed of the ancient Greeks, who did not use euvat, but euvæs.

Quality, it is to be observed, is an ambiguous term; and has been applied to some things which ought rather to have been looked upon as states of matter, or assemblages of several qualities; as life, health, beauty, &c.

There are, also, other attributes, as size, shape, motion, and rest, usually reckoned among qualities, which might more conveniently be ranked among the primary modes of the parts of matter; since, from these simple attributes, all the qualities are derived.

The ancient school-philosophers distinguish quality in the general, which they call metaphysical and predicamental quality, into essential and accidental. The moderns more usually divide it into spiritual and corporeal.

Qualities, Spiritual, or Qualities of the Soul, are affections of the mind, considered as in this or that habit or disposition. Of these they make two kinds; the one belonging to the understanding, the other to the will; of the former kind are knowledge, opinion, certainty, doubting, &c. Of the latter are all the moral virtues and vices.

Vol. XXIX.
Qualities, *Corporal* or *Physical*, are what we chiefly consider under this denomination, and to which the definition above laid down is accommodated.

Philosophers are divided as to the nature of these qualities, or what they are in the body. The general language of the Peripatetic school is, that they are things distinct from the bodies themselves; and are superadded to them, or flow from their substantial forms: on which principle, they hold qualities to be real, and denominate them *accidents*; supposing them to be inherent in substances, though not in the relation of parts, but to be fullained by them as in a subject, and incapable of subsisting without them. In effect, the Thomists define qualities to be accidents following or arising from the form; in the same manner as quality is an accident following or arising from the substance.

The moderns absolutely explode the notion of qualities distinct from the body: and insist, that the powers by which bodies excite in us, the ideas of such qualities, are no other than the mechanical affections of the bodies themselves, *viz.* the figure, magnitude, motion, &c. of the parts of which they consist.

The principal considerations implied on by the reasoners to real qualities are, that these powers may be actually separated from the substances they inher in; as we see in light, heat, &c. That from these very qualities, considered as to many determinations, there arises a very great diversity in bodies; and that bodies, according to the diversity of their qualities, affect our senses very differently.

The adherents to the experimental way, on the contrary, account for all the qualities of bodies from mechanical causes. Thus all the phenomena of a clock, the motion of its wheels, its hands, &c. by which it strikes the hour, points the minute, day, moon's age, &c. do all evidently arise from the fingle spring; which we never imagine to have any particular powers by which it should be enabled to make such discoveries; nor any other principle but that of elasticity.

Why, then, may we not conceive, as to sensible qualities, that through, by virtue of a certain congruity or incoagulity in point of figure, texture, or other mechanical properties, the portions of matter they modify are enabled to produce various effects, on account of which the bodies are said to be endowed with qualities; yet these are not, in the bodies endowed with them, any real or distinct entities, or differing from the matter itself of such a determinate bigness, shape, and other mechanical modifications? Thus, though the modern goldsmiths and refiners reckon it among the most distinguished qualities of gold that it is fusible in aqua regia, whilst aqua forte will not work upon it; yet these attributes are not in the gold any thing distinct from its peculiar texture; nor is the gold we have now of any other nature than it was in Pliny's time, when aqua fortes and aqua regia were unknown.

We all know that the sun hath a power to harden clay, soften wax, melt butter, thaw ice, turn water into vapour, make air expand itself in weather-glasses, contribute to blanch linen, render the white film of the face swarthly, and moved grae yellow, ripen fruit, hatch the eggs of falk-worms, caterpillars, &c. and perform many other things, some of which seem contrary to others; yet these are not distinct powers, or faculies in the sun, but only the production of its heat, diffusified by the different textures of the body, it chances to work on, and the condition of the other substances concerned in the operation. And, therefore, whether or not the sun, in some cases, has any influence at all distinct from its light and heat, we see that all the phenomena mentioned are producible by the heat of common fire, duly applied and regulated. Some of the ancients, and particularly the Peripatetics, have distinguished qualities into *sensible* and *occult*.

Qualities, *Sensible*, or *Manifester*, are those arising from certain modifications of matter, and which become immediately the objects of our senses. Such are all those above-mentioned.

Though, in strictness, those only are said to be sensible qualities which affect one sense alone; as colour does the eye, sound the ear, &c.

These are sometimes, also, called *tangible* qualities, because they only produce their effect, *i.e.* excite their idea in us, when contiguous, or in contact with the organ.

Qualities, *Occult*, are certain latent powers arising from the specific forms of things, of which no rational solution can be given on any principles of physics.

Sensible qualities are usually subdivided into *primary* and *secondary*. See *Ideas*.

Qualities, *Primary*, or *General*, are such as are found in all bodies; or which agree to all matter, considered as matter, and therefore to the elements themselves. Such are extension, figure, motion, reft, solidity, impenetrability, and number.

Qualities, *Secondary*, or *Particular*, are such as result from a composition or mixture of elements, and do not agree to body as body, but as a mixt. Such are light, heat, cold, colour, sound, taste, smell, hardness, softness, fluidity, firmness, roughness, smoothness, opacity, transparency, &c.

According to Aristotle, and the Peripatetics, the primary, or elementary qualities, are those of the four elements themselves; *viz.* heat, cold, moisture, and dryness.

The secondary qualities, according to the fame, are all the reft; which are combinations or assemblages of the former elementary ones; as colour, odour, taste, &c.

To give an idea of Aristotle's method of accounting for these secondary qualities from these primary ones, we shall instance in his account of colour. All colours, then, says he, are generated of a mixture of the four elementary qualities; white, *e. gr.* is produced when the humidity furmounts the heat, as in old men, whose hair grows grey; black is produced when the humidity dries off, as in walls, tiles, &c. red. &c.

Among the school-philosophers we meet with other divi- sions of qualities; as *active*, and *passive*; *real*, and *intentional*.

Qualities, *Active*, are those by virtue of which effects and operations are actually produced on other bodies duly disposed with respect to them. Such are the heat of fire, the moisture of water, &c.

Qualities, *Passive*, are those by which bodies are dis- posed to receive the action of others. Such are inflammability in oil, &c.

Qualities, *Real*, are those which remain in the subject, and only act on things adjacent to it. As fire in a piece of iron not ignited, &c.

Qualities, *Intentional*, are those which issue from the subject, and operate at a distance. Such is the light emitted from the sun, &c.

But the moderns are agreed, that either all qualities are real, or all alike intentional. So that the distinction is impermanent. See on the subject of quality, its various specific, and its different properties, Harris's Philosophical Arrangements, chap. viii.

However ignorant we may be of the nature of qualities, or of the manner of their operation, yet we know the laws of their intention and refection. Dr. Keil demonstrates, that every quality which is propagated in order, such as light,
light, heat, cold, odour, &c. has its efficacy increased, or abated, in a duplicate ratio of the distances from the centre of radiation, or exertion of the quality, reciprocally.

Thus, let 

A

(Plate XII. Geometry, fig. 1) be a centre from whence any quality exerts itself round about, according to the right lines, A e, A f, &c. The efficacy of the quality, be it heat, cold, odour, &c. will be (in equal distances from A) as the square of density or intensity of the rays, A b, A e, A f, &c. But the rays within the inner circle, or rather spherical superficies, b e d f, when they come to be extended to the other spherical surface, e f g, will be much less close than they were before, and that in the reciprocals of the squares of the spaces they take up: that is, if the outer surface be the double of the inner, the rays there will be but half as thick; but since spherical superficies are as the squares of their radii, therefore the efficacy of the quality in the inner surface will be to that of the outer, as A e square to A b square. Q. E. D.

Sir Isaac Newton lays it down as one of the rules of philosophizing, that those qualities of bodies which are incapable of being intended and remitted, and which are found to obtain in all bodies in which the experiment could ever be tried, are to be esteemed universal qualities of all bodies. See Philosophizing.

Qualities, Cognitae. See Cognis Qualitates.

Quality is also used for a kind of title, or degree of eminence given to certain persons, in regard of their territories, dignities, or other pretensions.

Thus the king of Great Britain used to take the quality of king of France; the king of Poland that of king of Sweden; the king of Sardina that of king of Cyprus and Jerusalem; the czars of Russia, and kings of Spain, have whole pages of qualities. The emperor of China affixes the quality of fan of the fun.

Quality of Curvature, in Geometry, is used to signify its form, as it is more or less inequal, or as it is varied more or less in its progress through different parts of the curve. Newton's Meth. of Flux. and Inf. Ser. p. 75. Maclaur. Flux. art. 569. See CURVATURE.

Qualities of Trees and Plants. Agriculture and Gardening, are the properties which are peculiar to them, in relation to their magnitude, modes of growth, textures or consistencies, forms, colours, tastes, smells, means of propagation, culture, uses, and values.

In regard to the first, as soon as the simple constituent fibres of plants are evolved and incresed, as far as the nature of them and the arrangement of the primary nutrient substances will permit, they cease to receive any more for their farther increase; the primary matters merely replacing the loss which is occasioned by the performance of the natural functions of the plants; consequently they have each a particular prescribed increate or measure of growth. Some are very large, others extremely small. The Indian fig, in consequence of ramifications being sent off, which concrete with the primitive trunk, by indefinable degrees acquires a very considerable bulk or thickness, being frequently twenty, or even thirty cubic feet in its diometric section. And there are accounts given of particular plants, which are scarcely visible to the naked eye; and of some trees, which are so large as to cover with their branches two hundred persons, or more.

In this country, some trees and shrubs of the ornamental fort are either very high, or very low; of the former kind are the horfe-chefnut, larch, cornelian cherry, snowdrop-tree, and many others; and of the latter, the mountain-ale, hemlock, fir, Scotch rofe, butchers' broom, and many more. There are some trees which are very broad, in proportion to their height, as the oak, Spanish chemnut, &c.; others which are very narrow, as the larch, spruce fir, &c. And there are full some others, in which there is a medium between these extremes, preferred and kept up, as in the ash-leaved maple, the evergreen oak, the Virginia rafberry, the Guelder rose, and a number of others.

The modes or habits of growth in trees and shrubs are also extremely different; some finding out their branches in a horizontal manner, as in the oak; in others they have an upward direction, as in the Huntington willow; while in a few they fall downwards, as in the lime, acacia, and others. Again, there are some which have an oblique inclination, as may be seen in the Scotch fir; or they recline, and then rise up again, as in the larch kind; and there are full others, in which they hang directly downwards, as in the weeping ash, weeping willow, &c. There are likewise some shrubby plants, which creep along the surface of the ground, as the periwinkle; others which clasp themselves to trees, as the passion-flower; and a few which fix and attach themselves to buildings, walls, &c. as the ivy. Farther, there are some trees that, in whatever way their branches extend, are not pruned, constantly affume and take; on one principal item, from which all the different branches proceed or go off, as rays from a centre, as in the fir tribe; while in others, the trunks divide themselves into arms, or large branches, which send out boughs or smaller branches in an irregular manner, as in the oak and others. Some kinds of shrubs have merely one single item, as the althea; while other forts invariably spread and extend along the surface of the ground, throwing or fending up a greater number, as the hypericum, and some others.

The texture or consistency of plants of different kinds is likewise very different, as hard, soft, membranous, carnose, smooth, downy, thorny, &c. which are molyly obvious to the feel. Plants of the young kind are commonly mucilaginous, becoming hard as they advance in growth; though many luxuriate in the slate of continual softness, as the trema; yet some are so hard as to sink in water, as the iron wood of the island of Ceylon, &c. Thus among trees and shrubs, some have a soft smooth appearance, as the lime, the porpion fenna, &c.; while others have a hard, rough, firm appearance, as the evergreen oak, the holly, &c. There are some also which have a smooth, silky appearance, as the tamarisk, &c.; while others have a downy, woolly appearance, as the hoary poplar, &c. And some appear wholly beft and covered with thorns or prickles, as the furze, hedgehog holly, &c.; while others, again, appear wholly composed of thready shoots, as the Portuguese broom, &c. Besides these, there are many other forts, which furnish different appearances from any of these.

The forms in the different forts and varieties are all equally, if not more, various; some being apparently solid and compact, from being thick set with branches and foliage, as in the horfe-chefnut, the English elm, the lilac, the fyrings, &c.; while others are of a more light, airy, elegant form, being thin of boughs, branches, and leaves, as the alth, the hoary poplar, the bird cherry, the Canadian mepilis, &c.; and there is a middle degree between these extremes, in the broad-leaved eucyamus, the afh-leaved maple, and some others. They may also be further distinguished into those whose branches begin from nearly the surface of the ground, as in the fir tribe of trees, and most shrubs; and into those which shoot up into a stem before their branches are begun to be sent off, as in the mountain-alth, the althea frutex, &c. It may likewise be noticed in respect to those whose branches begin from the ground, that some of them rife in an elegant cone, as the larch, the Z 2 holly,
holy, &c.; others in a cone, whose base is very broad, as in the cedar; or whose base is very small, as in the upright cypresses. There are some which swell out in the middle of their growth, and diminish or contract at both ends, as in the Weymouth pine, &c.; while others are broadest at the top, as in the raphan, the alpine honeyfinkle, &c.; and some few irregular and bulby throughout, as in the ever-green oak, the snowball tree, &c. Among these which shoot up into a stem before their branches are sent off, there are some which are in the shape of slender cones, as in the deciduous cypresses; others in those of broad cones, as in the balsam poplar. Still others assume a globular form, as in the mountains-holy; while many are irregular throughout, as in the Scotch elm, the acacia, and several others.

As to colour, it appears to depend upon the colouring principle, the proportion of vitre air and light which is contained, and is proper to different parts of the same tree or plant; hence, when exhaustion is prevented, and light intercepted, the green colour is changed into white. In trees and shrubs it is either accidental or permanent: the latter including all the different shades of green in the summer months; the former, the different tints of red and yellow, which are peculiar to the autumnal and vernal foliages.

There are some of the permanent kinds of colour, which are of a dark green, as those in the horse-chestnut, the yew, &c.; while others are of a light green, as those in the ash, the common laurel, &c.; and others, again, which are of a blue-green, as those in the Scotch fir, the bladder fern, &c. Some trees have a green tinged with brown, as the Virginian cedar; others a green tinged with white, as the abelone and the Lapland willow. Also, in some trees the greens are tinged with yellow, as in the ash-leaved maple, the Chinese arbor vitae, &c.; in others with red, as in the scarlet maple, &c.; and in a few with purple, as in the purple beech. There are some greens which are spotted with white, yellow, and red, as in the variegated holly, privet, fycamore, box, and various others. The colours which arise from accident are almost infinite in number, each kind of which is liable to great variation; mostly, however, it will be found that in autumn the wild cherry assumes a bright red, the birch a deep red, the beech a brownish-red, the fycamore, a deep scarlet, the hornbeam a rutilent colour, the larch maple a rich yellow, the common oak a reddish-yellow, the lime and ash a straw colour, the balsam poplar a black, the fycamore a dark brown, and others different forms of other colours.

In regard to taste and smell, the former depends upon the different principles which compose and constitute the juices or humours of the different kinds, and varies as well in the different forms, as in the different parts of the same form of trees or plants. The latter depends upon the volatile principles, or principles, which issue or exhale from them, and differs in its nature, according to the kinds of plants, or the parts of them, in which it chiefly resides or is present. There are some trees and shrubs which have scarcely any smell, as the evergreen oak, platanus, &c.; others have a most grateful rich fragrance, as the birch, sweet-briar, honeyfinkle, &c.; some again have a luminous, powerful smell, as the mezereon, the lypings, &c.; others a disagreeable nauseous smell, as the elder, &c.; in fome the smell is very sweet, as in the darling vine; in others it is deleterious, as in those of the nutim, the artimia, &c. There is also the greatest fragrance in some while they are in blossom, as in the hawthorn, and in fome it is so entirely confined to it, as in the lily; while in others it is equally diffused over or throughout the whole plant, as in the sweet-briar, and many others.

These may be considered as some of the most general characteristics of trees and shrubs; but various other peculiarities incident to them present themselves, on a more minute investigation, which equally interest and deserve the attention of the ornamental planter and gardener, as well as the cultivator of all sorts of wood and timber; and which principally relate to differences in the barks, the buds, the leaves, the flowers, and the fruits. The appearance of the bark is very different in many different sorts of trees and shrubs, as red, white, black, brown, and green, as in the dogwood, birch, oak, Guelder rose, and holly. It differs also in its properties, as in fome it is firm, in others spongy, in some thin, in others thick, brittle, glutinous, or thready, as in the oak, the cork-tree, the beech, the Scotch fir, the hornbeam, the holly, the lime, and the elm. It varies likewise in its duration, the outer bark or coat in some trees being thrown off annually, as in the abrusus, the birch, &c.; while in others, for the most part, it is constantly retained or kept on. It differs equally in respect to its properties of taste, being in some alluring in its nature, in others sweet, bitter, relinous, &c., as in the oak and bramble, lime, abelone, &c. In regard to buds, some trees have none at all, as the pine and evergreen firs; in some they are very large, in others very small, as in the horse-chestnut, and the willow. In some they are coated over with a covering of glutinous or relinous matter, as in the horse-chestnut, &c.; in others they are overspread with a dry film or tegument, as in the beech, &c. There are likewise some buds which are of a red colour; others which are yellow, black, brown, or red and greenish; as those in the lime, the willow, the ash, the beech, and the common sycamore, in the order in which they occur.

The variety in the leaves is still much greater: some being very broad, as those of the common laurel; others very narrow, as those of the larch. And there is a medium between these extremes, in those of the willow and the alder. In some they are entire, as in the bay; in others serrated, as in the cherry; and pinnatifid, as in the acacia, &c. In some again they are covered with down, as in the sea buckthorn; in others with wool, as in the hoary poplar; with prickles, as in the holly; with a glutinous matter, as in the gum cistus, &c. They are of all the different shades of green in the summer season; and of all the different tints of red and yellow, in the autumnal and vernal seasons.

There are some which retain their leaves and colours during or throughout the whole year, as the pine tribe, &c.; others which lose their green colour in the autumn, but retain their leaves all the winter, as the beech, hornbeam, &c. in particular circumstances. A great number of trees, among which are the elm and the ash, drop their leaves in the autumn, and are naked all the winter. In general, the leaves have the same properties as the barks, but in a fainter and less perfect degree, which are of much importance in some points of view. Those of the alder, the box, &c. are reduced by moss, or ftone, as thistle, &c.; those of the fir tribe are offensive to many sorts of insects, which are liable to infest hot-houses, and other similar places.

And the flowers are much less various than the leaves. Those of some trees being large and flowery, as of the rose, the honeyfinkle, &c.; while those of others are small and obscure, as of the alaternus, &c. In some they cover the whole plant, and quickly fade away, as those of the hawthorn; while in others they are but thinly distributed, yet continue a considerable length of time, as those of the passion-flower, &c. There are some, which come into blossom at an early period, as those of the mezereon, almond, &c.;
In their more young growths trees and plants not only demand foils, situations, and aspects suited to their particular natures and habits, but also such methods of culture as are adapted to them. Some kinds requiring the earth and mould about their roots to be repeatedly dug up and flitted, as the lime, the lilac, &c.; others advance with equal rapidity, where the ground on the surface is preserved free and clean from other injurious vegetable productions, as the oak, the chefmut, &c.; while others again succeed in the belt manner, where the surface of the land is covered with moffy matter, as the rhododendron, the erica, &c.

In regard to cutting and pruning, there are some trees which will not bear the knife, as the cherry, &c.; the wood in others is many times hurt by it, as in the pine and the fir tribes. Some again are capable of bearing it to any extent, as the hawthorn, the crab-apple, &c. However, these peculiarities are mostly applicable to trees of considerate height; as most fowts when very young endure cutting in, and pruning very well, many kinds requiring these operations to train and bring them to single items. For instance, the silver fir, while in the nursery state, requires the side shoots of it to be cut and shortened; and young oak plants, some time after they have been finally planted out, are often cut over just above the surface of the ground, and suppose to grow up stronger by it.

A great many fows of trees and plants stand in need of being removed or transplanted the first or second year of their growth from the seed, while in the nursery ground; and to be set out from that situation into plantations of different kinds, while under the height of four feet, or in their more early growth. There are some fows which are little or not at all hurt by such removals, as the elm; while others are liable to die after it, as the spruce fir, the Weymouth pine, &c.; some kinds are also apt to die on being transplanted, after they are eight, ten, or more feet in height, as the pine, the fir tribes, &c.; while others may be safely transplanted at nearly double such ages and fizes, as the lime, the elm, the fycamore, and various other deciduous kinds; however, a year or more before their removal is to take place, they should have their roots cut in, and their tops thinned by the pruning knife, or other means, as fuch precautions are highly important and necessaey, and should never be omitted, in removing trees of the latter of the above heights.

In respect to the uses of trees and shrubby plants, though the latter fort are commonly fet out for the purpose of ornament, variety, &c., and the former for that of timber, as well as thefe and other uses; there are stil some other ways in which they occasionally contribute, and become of utility and importance to the planter. There are different products of some of them, which are useful in different arts and professions. For instance, the bark of fome is useful in cheffistry, for the making of bird-lime, as that of the holly; that of others, as of the lime, the elm, &c. for the manufacturers of masts. The leaves of fome, as thoee of the mulberry, for the growers and mifers of filk. The blossoms of others, as thoee of the rose, for the apothecary, and thoee of the syringa for the confecfioner. Thoee parts of the feed of the bee when fat proper are converted into brood. And the fruits of others, as thoee of the walnut, apple, plum, &c. are of very general utility and value.

Some kinds of wood are of particular use and value for particular purposes, as the oak to ship-builders; and others might be trained for this application, as the larch, by bending down the stem when about twenty feet in height, securing it in that position, and then re-bending it again some consider-
able time afterwards, leaving the hole or trunk in a differently crooked state. The woody parts of the fir and pine are employed by house-carpenters, of the crab-tree by millwrights, of the ash by ploughwrights, of the beech, the walnut, the cherry, the plum, the box, the holly, the yew, and others, by the cabinet-makers. The lime is particularly useful to the carver, the fycamore to the turner, the oak and holly to the mathematical instrument-maker, and the elder and the birch to the left and the heel-maker. Charcoal of any of the kinds is valuable for the iron-founders; that of the dog-wood, fallow, elder, hazel, &c. for the gunpowder manufacturers. The larch, the fir, sycamore, &c. afford the coarse turpentine and the spirit; the fycamore and pine tribes, fir, pitch, pitch-black, &c. Moll woods, but particularly the beech, ash, elm, &c. afford potash. The sap-juice of some trees, as the birch, &c., yields a vinous liquor; and that of others, as of the sugar-maple, affords sugar.

The value of wood as timber, and for other purposes, differs much according to local situation, and other circumstances; when near a dry-duck or ship-yard, oak, elm, &c. suited to ship-building, are of much higher value than when at a great distance in the country. The undergrowths of several sorts of trees, as dog-wood, fallow, willow, alder, &c., are of the most value when near large manufactories of gunpowder, being of little utility, except as fuel, when at a distance. Some sorts of wood, however, from the generality of their application and employment, are of great value in all situations, as those of the oak, the elm, the ash, the beech, and perhaps the larch has still more value than any of them. Others, on account of their scarcity, are also valuable in all places, as the box, the holly, the yew, &c. All the lighter products of some sorts of trees, as those of bird-line, potash, turpentine, tar, pitch, &c., may likewise be considered of equal value in all situations. But a tree which would be of the greatest value in a particular situation or place, may not find in it that sort of fuel that is suitable to its nature or habits of growth; in which circumstances that which will come to the most perfection in it, will commonly be found of the most value. Such woods as may not be valuable in consequence of local circumstances, may be rendered a great deal more high in their value, by having them manufactured in the places where they are needed; thus lessening the expenses of conveyance, &c. In consequence of the great improvements in roads, canals, &c. and the general promotion of woods, and plantations for timber, fuel, in almost all places, be valuable, and there can be few in which the other sorts of products will not be of great importance. In measuring and standardising trees for the purpose of ascertaining their value, though many think themselves fully qualified by being simply able to measure them; it is only by the perfect knowledge of the use and application of the different shapes, bends, and woods of them, that a correct estimate can be given; as a small portion of wood may be of little consequence in one sort of business, while it is of much in another, which is a secret of great interest and importance to the purchasers of timber of the standing kind.

In addition to these qualities, almost every tree and plant is possessed of various others, which excite emotions that have a relation to them, and which give their characters or expressions. For instance, the cypress is of a regular, invariable shape, or form, and always, in colour, of a dark green, having a still, solemn appearance; hence it has acquired the character of melancholy. A fir, but somewhat fainter, train of emotions, is produced in the mind by the falling branches, drooping spray, and yellow greenish colour of the weeping willow; hence it suits with scenes of solitude, and induces meditation. In the light, airy form of the ash, and the bright white of the variegated holly, there are some traits of certain degrees of the cheerful kind; in the fellos of the virgin’sbower, eafe and gracefulness; in the myrtle, delicacy and neatness; and in the sweep of the stem, the curve of the branches, &c. of the larch, a peculiar elegance. In the oak and the chestnut are forms which have been given the name of grandeur and sublimity. Both these and other trees are particularly expressive of peculiar known characters, arising, in some degrees, from their own nature, and in part from associations in the mind. Those of the cypress and yew kinds have been planted in burying grounds, and other similar places; the weeping willow, as the shade of urns; the laurel used as the crown of warriors; and the chestnut introduced in landscapes.

Some accidental characters and expessions of plants are produced by novelty and singularity either in their natures, forms, or appearances; hence exotics are at first distinguished from those of the indigenous kind, and called beautiful, elegant, fancifull, strange, rare, &c. according to circumstances. The creeping ash, the pine, &c. derive and retain their characters from their comparative scarcity and unusual shape; while others have that of elegance and novelty in a much less degree, as the cedar of Lebanon and the cypresses; the hemlock spruce, and the scarlet oak, &c. Some trees and plants are common, and thought nothing of in one district or country, while, in others, they are uncommon, and thought highly of; thus, the weeping willow, the narrow-leaved elm, the acacia, &c., which abound, and are little valued, in the southern parts of the island; are scarce, highly esteemed, and termed elegant in those of the north; while the arbustus, the uva urbi, the erica alba, and even the mountain-ash, which are plentiful, unnoticed, and common in the north, are held in estimation, and thought highly elegant in the south.

There are some of the more particular qualities of trees and plants, which are concerned in the classification and arrangement of them, as the materials by which the objects of planting and ornamental gardening are to be accomplished, but there are others which are peculiar to them in other points of view, that it is quite unnecessary to notice in this place, as they are fully explained in speaking of them individually under their proper heads.

More ample information on the above subject may, however, be obtained by consulting Mr. Loudon’s work “On Forming, Improving, and Managing Country Residences,” in which will be seen their particular utility, and their most appropriate modes of application in the busines of planting and ornamenting different kinds of pleasure grounds, under all the various circumstances which may occur in so far as their nature, situation, soil, and other similar particulars are concerned, as well as the picturesque effect which will be produced.

Qualities of Seeds, Sets, and Produce, the properties which are essential to them for the production of full and beneficial crops of the several different kinds, and the most perfect and advantageous states of growth and maturation of such crops, for their being consumed, either as food or otherwise. In all sorts of seeds of the grain kind, those which are the most fully bodied, bright, thinset in the skin, and the most sound, without being too long kept, are the most suitable for making use of as feed. Such as are small, lean, ill fed, and shrunk in their skins, or which have been in any way heated in the mow or stack, are, mally quite improper for this purpose. Some have, however, popularised the contrary to be the case, but they have hitherto adduced no proofs whatever, of the fact, while the former opinion is supported
supported by the daily experience of the belt farmers in the country. There is another circumstance which is of some importance in this business, which is that of the grain for this use being constantly newly threshed out from the straw, as such, for the malt part, sprouts and grows more expeditiously, and is less liable to rot and perish in unfavourable seasons and situations.

All sorts of dried grain, and such as is not perfectly free from the mixture of the seeds of weeds with it, should always be, as much as possible, avoided in this intention.

In regard to the smaller sorts of feeds for raising all kinds of plant-crops in the field, as well as those of the grasses, both natural and artificial, the principal necessary qualities, in each, are those of their being of a bright, lively, shining colour, perfectly found, and fresh, or lately collected from the plants. Such as are old, or kept more than a few months, are mostly improper for this application. The belt sorts commonly slide freely over each other, without sticking or being heavy in the hand, and have a brilliant bloomy appearance.

In gardening, most sorts of feeds also are the belt, and require to have these properties and qualities as much as possible; but there are a few which are apt to grow too luxuriantly for fruiting well, as some of the cucumber, melon, kidney-bean, and other sorts, which are better for being kept for some length of time, as this property is thereby in some measure corrected and restrained. Most sorts of nuts and stolones, when used as feed, should, however, be employed in as fresh a state as possible.

Sets are different in their nature, being of the root or plant kinds. In the former, the sets or cuttings should have the eyes or buds in a perfect state, and be of a muddling size, as both these which are very large and very small are objectionable. This is the case with the potatoe and some other sorts. In the latter, the plants should not have too large growths, but be in a fine young state of vegetation, so that they can be set out with facility, and readily take root again, having their heads or upper parts, for the production of the produce, wholly in an uninjured condition. They should also be quite newly drawn up, cut of from the stalks of the old plants, without any sort of clubbing near the roots in those which are drawn. Such as have risen the most quickly from the feed, are, in general, the best. They should none of them ever be kept any great length of time after being drawn, before they are re-planted. This is equally applicable to the field and garden kinds. See Seed, Set, and Sowing.

The produce in all the white or grain crops, which are employed either for the purpose of mealing or maltin, should constantly be well ripened; but where the straw is to be made use of as cattle feed, the crops are better to be cut before they have reached the state of full maturity, as this purpuse is thereby more completely answered. There is much loss in the produce of most sorts of field plant-crops, by taking them before they have formed their bulbs or heads in a perfect manner. But many of such like products, in the garden, are the belt and most advantageously taken in such imperfect states, being tough and coarse when fully grown, and without the necessary tenderness. Others require to be cut or drawn early in order to have the proper degrees of sweetness and flavour. The fruit kind of produce is taken both before and when nearly ripe, according to the uses for which it is intended. Some sorts of vegetable produce are used quite in their green state, as food; while others are best in a somewhat more advanced state: and others, again, in both these states. And there are those which require to be well ripened, and kept for some length of time before they are used in this way.

All sorts of produce of the grasses-kind, are cut and used to the most benefit, when they are taken a little before they become perfectly ripe, as they go the farthest, whether they are to be consumed in the green state, or in that of hay. This is equally the case with the more luxuriant artificial sorts, as with those of less growth, of the natural kind. This is explained more fully in speaking of the different plants and crops individually, and in the article Hay; which see.

QUALO, in Geography, a town on the N.E. coast of Sumatra. N. lat. 2° 45'. E. long. 99° 30'.
QUALUGA, a town of Africa, in the country of Whidah; 18 miles N.W. of Sabi.
QUAM, a town of Norway, in the diocese of Drontheim; 68 miles N. of Drontheim.
QUAM du le less gierit, a clause frequent in letters patent, or grants of offices, to secure them so long as the persons they are granted to shall not be guilty of abusing the same.

Thus, e.g., we find it in those given to the barons of the exchequer: where it intimates, that they shall hold the same as long as they shall behave themselves well; which is to be restrained to matters of their offices; and signifies no more than the law would have implied, had the office been granted expressly for life. See Judge.

A grant therefore, with this clause, is equivalent to a grant for life.

QUAMASH, in Botany, a name given, by the North American Indians, to a plant called Phalangium Quamosa, by Mr. Pursh, in his Flora, v. 1. 256; who nevertheless mentions an irregularity in the petals, that might possibly etablish it as a new genus. See Phalangium.

This plant was observed by governor Lewis, about the upper part of the Missouri, near the Rocky-mountains, flowering in June. The bulb is roundish, tunicated. Stem none. Leaves radical, few, long, and linear, half an inch broad, smooth; keeled underneath. Flowers stalk solitary, naked, erect, round, smooth, unbranched, a foot or more in height, terminating in a spike, or rather cluster, of large, blue flowers, each accompanied by a linear, membranous, withering bracteae, longer than the partialstalk. Petals linear-lanceolate, nearly equal in length; five of them ascending; the sixth deflexed. The bulbs are carefully collected by the natives, and cooked between heated stones, when they assume the appearance of baked pears, and have an agreeable sweet taste. They form a great part of the winter stores of those Indians. Though governor Lewis's party found them a pleasant sort of food, they could not be eaten, in any quantity, without causing bowel complaints.

QUAMCLIT, an Indian name, retained by Plummer and Tournefort as generic; but by Linneaus used only as the specific appellation of a beautiful species of Tristits; see that article.

QUAMPEAGAN FALLS, in Geography, falls in America at the head of the tide on Newichwanock river, which joins Picataqua river, 10 miles from the sea; so called by the natives, because fish were there taken with nets. At these falls are a fet of saw-mills and others, and also a landing-place, where great quantities of lumber are rafted. Here the river has the English name of Salmon Falls river, from the number of salmon caught there. On many places from Quampeagan to the pond, from which it issues, there are mills for boards and corn.

QUAM-TOM, a town of China, of the third rank,
QUA

in the province of Yun-nan; 15 miles N.E. of Tchou-hiong.

QUAN, a town of China, of the third rank, in Chantong; 22 miles W. of Tong-tchang.

QUAN, or Quan, in Ornithology. See Penelope Grifista.

QUANAMORA, in Geograpy, a town of Africa, in Upper Guinea, on the banks of the Scherbro, said to contain 5000 families. N. lat. 7° 45'. W. long. 10° 15'.

QUANDROS, a name given by writers of the middle ages to a fopne to which they attribute great virtues, and which, they say, is found in the head of a vulture.

QUANG-LING, in Geography, a town of China, of the third rank, in Chantong; 15 miles W.S.W. of Outi.

QUANG-NING, a town of China, of the third rank, in Quang-tong; 35 miles N. of Tchau-king.

QUANG-PING, a city of China, of the first rank, situated in the northern part of the province of Pe-tche-li, between the provinces of Chang-tong and Ho-nan, which has nine towns of the third class dependent upon it. All its plains are well watered by rivers. Among its temples, one is dedicated to thatle men, who, as the Chinese pretend, discovered the secret of rendering themselves immortal.

212 miles S.S.W. of Peking. N. lat. 36° 47'. E. long. 112° 25'.

QUANG-PUNG, a town of China, of the third rank, in Pe-tche-li; 17 miles N.W. of Tay-ming.

QUANG-SI, a province of China, situated between those of Quang-tong, Hoo-quang, Kwe-tcheou, Yun-nan, and the kingdom of Tong-king; about 350 miles from E. to W., and 250 from N. to S. In commerce, as well as extent, it is not equal to that of the other provinces; and yet it fo abounds with rice, as to supply, for six months in the year, the province of Quang-tong, without which the inhabitants of this province could not subsist.

The mountains with which it is covered, abound with mines of gold, silver, copper, and tin, and in this province is a singular kind of tree, containing a soft pulp, which yields a fort of flour, and of this flour they make a very good bread. Besides parroquets, hedge-hogs, and the rhinoceros, wild animals, curious birds, and uncommon insects are found here in great number. This province contains twelve towns of the first class, and eighty of the second and third. Its capital is Quei-ling. Groffier's China, vol. i.

The population of this province is estimated by Sir George Staunton at 10,000,000; its area comprehends 79,456 square miles, or 50,871,840 acres. The revenue remitted to the imperial treasury at Peking, comprising land, salt, and taxes, is rated at 500,000,000, or ounces of silver. The military force is said to amount to 50,000 men. Its capital is Canton; which see.

QUANG-YANG, a town of China, of the third rank, in the province of Quang-f; 50 miles S. of Tien.

QUANG-YUEN, a town of China, of the third rank, in the province of Se-tcheou, seated on the Kialing; 50 miles N. of Pao-king.

QUANNEFORD, a bay on the W. coast of West Greenland. N. lat. 62° 10'. W. long. 48° 5'.

QUANO, a town of Japan, on the island of Niphon, on the S. coast, 70 miles E. of Meaco. N. lat. 35° 58'. E. long. 136° 14'.

QUANTALLA, an island of Africa, at the mouth of the Zaire, celebrated for a silver idol, to which the neighbouring kings send presents and offer sacrifices.

QUAN-TAO, a town of China, of the third rank, in Chan-tong; 25 miles W.N.W. of Tong-tchang.

QUAN-TCHANG, a town of China, in Chan-tong; 15 miles N. of Po.

QUAN-TITE, Tr. This word in music, like profody, does not fix the number of notes or of syllables, but their relative duration. Quantity produces the rhythm, as accent produces intonation. Rhythm and intonation generate melody. Rouleau. See MELODY.

QUANTITY, Quantitas, any thing capable of elimation or menfuration; or, which being compared with another
other thing of the same kind, may be said to be greater or less than it; equal, or unequal, to it.

Mathematics is the science or doctrine of quantity.

Quantity is a general attribute, applied in a very different manner to things of different nature; whence it is impossible to give any universal definition of it.

Quantity is applied both to things and to modes; and this either singularly to one; or plural, or to several. In the first case it is called magnitude, in the latter multitude.

Quantity may be reduced to four classes; viz.

Quantity, Moral, which depends on the manners of men, and the free determination of their wills. As the prices and value of things; degrees of dignity and power, good and evil, merit and demerit, rewards and punishments, &c.

Quantity, National, arising from the operation of the understanding only. Such as the largeness or narrowness of the capacity of the mind, and its conceptions. In Logic, universal, predicaments, &c. In Grammar, the quantity or measure of syllables, accents, tones, &c.

Quantity, Physical, or Natural, which is of two kinds: 1. That which nature furnishes us with in matter, and its extension. And, 2. In the powers and properties of natural bodies: as gravity, motion, light, heat, cold, rarity, denity, &c.

Quantity, Transcendental; as duration, the continuation of any being, existence, time, &c.

Quantity is also popularly distinguished into continued and discrete.

Quantity, Continued, or Continuous, is when the parts are connected together, and is commonly called magnitude. This again, is of two kinds; either successive, or improper, as time.

Quantity, Discrete, is when the parts of which it consists exist differently, and unconnected together; which makes what we call number or multitude.

The notion of continued quantity, and its distinction from discrete, appears to some without foundation. Mr. Maehlin considers all mathematical quantity, or that for which any symbol is put, as nothing else but number, with regard to some measure, which is considered as one; for that we cannot know precisely how much anything is, but by means of number. The notion of continued quantity, without regard to any measure, is indistinct and confused; and though some species of such quantity, considered physically, may be described by motion, as lines by the motion of parts, and surfaces by the motion of lines; yet the magnitudes, or mathematical quantities, are not made by the motion, but by numbering according to a measure. Vide Phil. Trans. No. 447. p. 228.

Permanent quantity is farther distinguishable into length, breadth, and depth.

Wolius seems to give us a more precise notion of mathematical quantity, and its two species of discrete and continued. Whatever is referred to unity in the same manner as one right line to another, is what we call quantity; or number in general.

If, now, the thing be referred to a given unit, as 3, it is called a determinate number; if to unity in the general, or at large, it is called a quantity; which, on this principle, is the same with indeterminate number.

Thus, e. g., the breadth of a river is accounted a quantity; if, then, it be enquired how great it is; to conceive its quantity, we take some unit at pleasure, and see the relation of the breadth to it; and according to the different unit assumed, we express the breadth of the river in a different determinate number.

Vol. XXIX.

The breadth of the river, therefore, is quantity considered as referred to a vague unit, or to unity at large; but the unit being determined, the thing is understood by a determinate number.

In this sense, algebra is the arithmetic of quantities. See on the subject of quantity, Harris's Philosophical Arrangements, chap. ix.

Quantity of Action. See Action.

Quantity, Impossible, and Imaginary. See Root.

Quantity of Curvature at any point of a curve is determined by the circle of curvature at that point, and is reciprocally proportional to its radius. Newton's Meth. of Flux. and Inf. Series, p. 60. Maclaurin's Fluxions, b. i. c. xi. See Curvature and Evolute.

Quantity of Motion, in Mechanics, is of two kinds; viz. of momentary motion, and of entire motion.

Quantity of entire motion. The Cartesians define the entire motion as the momentary one, by the factum of the mafs, or quantity of matter, into the velocity; but since motion is a successive being, and has no parts co-existing together, its quantity ought to be estimated by the aggregate of the several parts existing successively; and is therefore equal to the factum of the momenta into the time.

Quantity of momentary motion is the factum of the velocity into the mafs; or it is a measure arising from the joint consideration of the quantity of matter, and the velocity of the motion of the body; the motion of any whole being the sum or aggregate of the motion in all its several parts.

Hence, in a body twice as great as another, moved with an equal velocity, the quantity of motion is double; if the velocity be double also, the quantity of the motion will be quadruple. Hence, the quantity of momentary motion coincides with what we call the momentum, or impetus of a moving body. See Force.

In the collision of bodies, the quantity of momentary motion, which is found by taking the sum of motions tending the same way, or their difference, if they tend towards contrary parts, is not at all changed by any actions of the bodies on one another. See Percussion.

Quantity of Matter in any body, is the product of the density into the bulk; or a quantity arising from the joint consideration of its magnitude and density.

As, if a body be twice as dense, and take up twice as much space as another, it will be four times as great. This quantity of matter is the best discoverable by the absolute weight of bodies. See Matter.

Quantity, Infinite. See Infinite Quantity.

Quantities, in Algebra, are indeterminate numbers, or things referred to unity in general. See Number.

Quantities are properly the subject of algebra; which is wholly conversant in the computation of such quantities.

Cite quantities are used to be noted by the first letters of the alphabet, a, b, c, &c. the quantities bought by the last, x, y, z, &c. See Characters.

Algebraical quantities are chiefly of two kinds; positive, and negative.

Quantities, Positive, or Affirmative, are those which are greater than nothing, and which are affected with the sign + prefixed; or supposed to be so.

Quantities, Negative, or Privative, are those less than nothing; which are affected with the sign — prefixed;

Hence, 1. Since + is the sign of addition, and — the sign of subtraction; a positive quantity is produced by adding any real quantity to nothing: e.g. 0 + 3 = 3; and a + a = a. And a privative quantity is produced by

A a
by subtracting any real quantity out of nothing; e.g.
\[0 - 3 = -3\] and \[0 - a = -a\].

For an illustration. Suppose when you are quite deli-
tuate of money, somebody gives you a hundred pieces; you
have then a hundred pieces more than nothing; which pieces
constitute a positive quantity.

On the contrary, suppose you have no money, yet owe a
hundred pieces; you have then a hundred less than
nothing; for you must pay a hundred pieces to have just
nothing. This debt is a negative quantity.

Thus in local motion, progress may be called a positive
quantity, and regression a negative one; because the first in-
creases, and the second diminishes the space passed over.

And in geometry, if a line drawn towards any part be
accounted an affirmative quantity, another the contrary way
will be a negative one.

Positive or negative quantities, therefore, are equally
real with positive quantities, but opposite to each other, so
as to take away each other's effect, in any operation, when
they are equal as to quantity. Thus \[3 - 3 = 0\], and
\[a - a = 0\]. However, though \[+a\] and \[-a\] are equal as
to quantity, we do not suppose in algebra, that \[+a = -a\];
because to infer equality in this science, they must not only
be equal as to quantity, but of the same quality, that in
every operation the one may have the same effect as the
other.

A negative quantity is said to be less than nothing,
because it is opposite to the positive, and diminishes it when
joined to it; whereas the addition of \[0\] has no effect. But
a negative is to be considered no less as a real quantity than
a positive. Quantities that have no sign prefixed to them
are understood to be positive. See Negative Sign.

Quantities, commensurable, compound, exponential, hetero-
genous, like, rational, simple, transcendent, and variable.
See the adjectives.

Quantities. Addition of. 1. If the quantities denoted
by the fame letter be affected with the fame sign, the
numbers prefixed to them are added as in common arithmetic.
2. If they be affected with different signs, the addition
is changed into subtraction; and to the remainder is prefixed
the sign of the greater.
3. Quantities denoted by different letters, are added by
means of the sign \[+\]; as in the following example:
\[
\begin{align*}
4a + 2b - 2c - d - g &= a - b \\
5a - 2b + 6c + 2d - 3g &= e \\
9a + 4c - 3d - 4g &= a - b + e
\end{align*}
\]
See Addition.

Quantities, Subtraction of. See Subtraction.
Quantities, Multiplication and Division of. See Mul-
tiplication and Division.

Quantities, Combination of. See Combination.

1. If a positive quantity be multiplied or divided by an-
other positive quantity, the result is also a positive quantity.
2. If a negative quantity be multiplied or divided by a
positive, the result is a negative.
3. If a negative quantity be multiplied or divided by an-
other negative, the result is a positive.
4. If a positive quantity be multiplied or divided by a ne-
gative, the result is a negative quantity. See Multiplicati-
on, in Algebra.

Quantity of a Degree. See Degree.

Quantity of an Eclipse. See Eclipse.

Quantities of Seeds, Sets, and Plants, in Agriculture,
the proportions of each, which are necessary for raising
good crops of the different kinds. The ascertaining of the
most useful and beneficial quantities, in the several cafes,
depends, in a material degree, upon a number of different
circumstances, such as those of the situation, the nature and
quality of the soil, the period of sowing, the date of the
seeds, the manner of putting them into the earth, and se-
veral others.

A great deal more seed, sets, and plants, are requisite
in late situations or backward seasons, heavy, wet, stiff
lands, and late sowings; than where they are more forward,
more light and dry, and put in early. And far less quan-
tities made use of in the drill and dibble methods of put-
ting in the crops, than in that of the broadcast, or by the
hand.

In most sorts of white, or grain crops, the quantities are
from two to five bushels per acre, being more in barley
and oats, than in those of the other kinds, as from three to five
in general.

In those of the pulse kinds, usually from six or seven
pecks, to two, three and a half, and four bushels, being
commonly the latter, or more, in some sorts of beans.

In those of the small seed description, as the buck-wheat
and turnip sorts, from one to two and three pounds; but in
the cabbage kind, only from six ounces to half a pound,
and a quarter or half a peck.

In the tap-rooted crops, as the carrot, parsnip, mangle-
swede, &c. from two to five pounds, and sometimes fix.

In lettuce crops, in the field, from three to four pounds
the acre.

In different sorts of plantation crops, as those of hemp,
flax, woad, weld, teafel, &c. from two to three up to five
or six bushels, in the three first; but only from two to four
quarts, and from one to two pecks, in the two last.

The sets in the hop, madder, liquorice, and lavender kinds,
are from fix to seven hundred, and a thousand or more,
in the first, and two last; but in the madder from fifteen
to twenty thousand per acre. In the cabbage sort, from
eight hundred to a thousand and more plants or sets to the
acre. And in the potatoe the quantity of sets vary from
eight to twenty or more bushels to the acre, according to
the soil and manner of their being put into the ground.

The quantities of natural grafs feeds which are generally
employed upon the acre, are from two to four buifhels
and upwards. And those of the artificial grafs kinds, in the
clovers from ten to eighteen pounds; in fainftoain from
three to four buifhels; in lucern from fifteen to eighteen
pounds; tares from two to three buifhels; trefoil, three pottles of
cleaned feed, or two buifhels of the uncleaned fort. And
in chicory from eight to twelve pounds. See Seed, Set,
Plant, and Sowing.

The subject is more fully explained in speaking of the
clture of the different sorts of crops, and the most suitable
quantities under different circumstances put down.

Quantity, in Grammar, denotes the measure and
magnitude of the syllables; or that which determines them
to be called long, or short; or, it is the measure of time
required for the distinct pronunciation of a syllable.

This quantity is the object of prosody; and it is the
to regard to this that distinguishes verse from prose.

The economy and arrangement of the quantities, i.e. the
distribution of long and short syllables, make what we call the
meter.

The quantities are used to be distinguished among gram-
marians by the characters short and long.

The proportion between the long and short syllables may
be generally fixed the same as that between the every chat
and quaver in music; viz. as two to one. See Time.

Syllables are long or short, either by their nature, or by
accident; that is, on account of the place where they are
put
QUANTITY.

1. Except that a short vowel before two consonants, whereof the former is a mute and the latter a liquid, is common, as Αλάς ἐπιστέφων, etc. Δάκτυλον κατάδεικου. Hom. δα. τεθ. v. 45.
   *Note.* — In prose, elision, and epigrammatic verse, the syllable is more frequently short.

2. In dramatic poetry we may observe, 1st, that a short vowel before a short or aspirate mute followed by a liquid, and before a middle-mute followed by a, remains short. In tragedy the syllable, if not final, is often lengthened. 2nd, A short vowel before a middle-mute followed by a, u, o, lengthens the syllable in all dramatic poetry.

3. When the syllable is lengthened before two consonants, the vowel in pronunciation affixes one of them, as δι-αναγγέλει, -αναγγέλει, κοινοποιεῖ, κοινοποιεῖ, τίρτις, τίρτις. Hom. When the syllable remains short the vowel concludes it; as δι-αναγγελει, τιρτις.

2. A short vowel is sometimes made long before a single consonant, particularly before a liquid, as πώλαξ λαρυγγας. Hom.; παγας ρηματα. Hom.

   *Note.* — It is generally long before ε, which with its affinate appears to have been doubled in pronunciation; as παραμεριασθαι. This licence is not confined to a liquid, as στριφος, ιετος, Σκ. Hom.

3. A short syllable is often made long when the next word begins with a diphthongal vowel, as αι, ας, for Φητις. Hom. Μαθηταί δοθησαν for Φηταί δόθησαν; for Φηταί δόθησαν. Hom.

4. When three short syllables come together, it is necessary, on account of the measure in heroic verse, that one should be made long, as αδοκίς, Πραξις.

   *Note.* — This takes place even where the three syllables are in different words; as αδοκις, Πραξις, Παμ. H. O. 5. A vowel before another does not suffer elision, as in Latin, at the end of a word, unless an apopthrophe is subjoined.

   *Note.* — The elision of diphthongs takes place in verbs only: real instances of this are to be found only in the fragments of the new comedy.

6. A long vowel, or a diphthong, is generally shortened at the end, and sometimes at the beginning, of a word, before a vowel, as αις οι; Hom.; τενις, Soph.; † ις οις, Theoc.

   *Note.* — A long vowel, or a diphthong, may be considered as consisting of two short vowels. If the latter is supposed to suffer elision, the former will of course remain short; as αις οις.

Cراس, or Contradiction.

7. A contracted syllable is always long; as ος, ος, ος; ις, ις, ις.

8. Two succefsive vowels, forming two syllables, even in different words, frequently coalesce in poetry; thus δις becomes a monosyllable, κρώς a difficult syllable, and in ἀληθῆ, ος, στ ος, ἀληθῆ; Hom.; ης, ης are pronounced as one syllable.

Composition and Derivation.

9. Compound and derivative words follow the quantity of their primitives; as ἁπάξ from τίς, γίζων from διοίζω, τίς from τίς.

   *Note.* — Grammarians have sometimes complained that, "non temper hinc regulam intendam." But Dr. S. Clarke affirms, "Dixit pro eo, a quae parte sunt penitentias tansiter vel perpetuo corri- piunt, vel perpetuo producunt. Latinis habent leg, legi, quasi contra- traqum ex legi. Similiter sedes, sedi, indeque sades, sodi. Con- finimili quidem ratione, apud Graecos sit. Verba mirum innumerum sunt, quae in praecedentibus imperfici um omnibus et in soribus prim, activa et mediis, temper producunt: in futuris autem et aoritis secundis omnibus, temper corripiunt; ut ψειω, ιγιαται, ιγιαται, ψειω, ψειω, ιγιαται, indeque ψειω, ιγιαται, ιγιαται, &c. Κρίων, κρίων, κρίων; κρίων, indeque κρίων, κρίων, κρίων, &c. \\

QUANTITY.

31. As in, t, final are short; as α, δ, ἄνω; ειδή, ἐπιθάνον;

1. Except that α as is long in circumflexed words, and in oxytons masculine; as ἀπὸς, Τίτας.

2. These adverbs, αὐτός, ἑαυτός, ἑαυτῷ; and the accusative of the first declension, whole nominative is long; as Αἰδοίς, φιλία.

3. It is long in words of two terminations; as ἀδύνατος

4. Ποίευς and Ποίεσθε when circumflexed; οἱ ὄντες ἐν Ὀρεί.

Ποίεσθε is sometimes long in Homer.

5. Nouns in τοῖς, as περιήγησα, lengthen w final.

6. οὐ is long in words of two terminations; as ἃπειρος and ἀπηχθεί.

7. Accusatives from οὐ long; as ἀπειρος, with οὐ; though in the exclamative is short; as οὐ τε φύσι.

8. The imperfect and second aorist of verbs in υμι, as ἵππος, ἱππότης.

32. ήι final is short, ήι final long; as Νικήτης, αὐτεύς; ἕως.

Except that γάρ and αὐτή are sometimes long in Homer.

33. άς, ες, ος, final are short; as λαμπρός, μέγας, πολύς, ὁδός, ἐβολή.

1. Except that κό is long in the nominatives of participles; as νόμος: in all cases of the first declension; as ἀνίομεν, ταῦτας. Οἰκίας, μοῦ, except the Doric accusative; as νόμος; in plural accusatives in κό from the long κ in the accusative singular of nouns; in νι, and in nouns in κατο, as Αἰας; with παλαιος.

2. Also οὐ is long in words of two terminations; as ἀθλεῖει and ἀθλέται; in nouns in οὐ increasing long; as ἀθλεῖας, κριτικος, κτλ., κτλ.

3. And οὐ is long in words of two terminations; as οὐκετος and οὐκετος; in monosyllables, as μετώ, with οὐκετος; oxytons making the genitive in οὐ pure; as περιίκος; οὐκετος is common. And in verbs in υμι, as ἵππος, κτλ.

On Quantity in the Latin Language.

As the prody of the Latin language is considered to form an essential part of a classical education, we shall, therefore, devote the more peculiar attention to this part of the subject. In the course of which some rules will be given on the quantity of syllables usually said to be long or short by authority; which, we believe, have never yet been collected by any writer, ancient or modern. Perhaps, therefore, in particular for this, and for such other reasons as the sound of impartial discernment shall discover, we shall not incur the censure of having been too languidious, should we have indulged the hope of being enabled to offer the most complete system on Latin prosody that has hitherto been presented to the public.

GENERAL RULES.

A Vowel before a Vowel.

1. One vowel preceding another, in the same word, is short; as puer, egregius.

O Molibae, Deus nobis hae ota fecit. Virg.

2. The same happens, though an h intervene; as nihil, ãnehus, dénibus.

De nihilò nihil, in nihilò nil posse reverti. Perf.

Note.—H is generally considered only as a note of aspiration or breathing; though some ancient grammarians considered H as a constant, and ranked it with the finals in syllables. See Terentianus Maurus, de syll. 511.

1. Except
QUANTITY.

1. Except the i of fio is long, when it is not followed by e and r; as fiam, fiebam, fiat.

Omnis jam short, tibi quae possit negabem. Ovid.

2. The e of the genitive and dative of the fifth declension, when it comes between double i, is long; as faciel; but it is short in spei, and long and short in rei and fidei.

Ventric erat ad Velle quarum jam parte cli. Hor.

Etquae feminas, nee te dicit fili. Seneca.

Ilius recto ratione rediretque possit. Lucret. *

Curum mea qui dixerat sequerit rcl. Hor.

Ille vir haud magna cum re, sed pleno jflati. Enn.

Unum rectus habent, fideque immutabile vinculum. Mand.

* Lucretius furnishes five examples of rcl; Plautus two. These cases appear to have been analogously written both as and as, which accounts for the variation in quantity.

3. Genitives in in have the i long in prose, though in poetry it is common; as unus or unius, illius or illiis; except the i of alius, which (formed by means from alius) is always long, and the i of alterius, morel short.

Navibus, infandum: unius, nullius ob iram. Virg.

Partiue movent quibus semper et exiret. Ovid.

Tu poscis alterius studia horerete Minervae. Claud.

Max dum alterius * obligabur bona. Enn.

* Alterius is three times long in Terentianus; de syllab. 172, de metr. 52, and 464.

4. The penultimute is long in aura, auris, and other antique genitives of the fifth declension, and in such vocatives as Pompei, Caio; because these were originally written with a double i; thus, Pompei, Caio.

Etherum fenny, acque auris simplicis ignem. Virg.

Accep Pompei, deducere curnam ab illo. Ovid.

5. In obe, in io (whether interjection or proper name), and in Diana, the first syllable is common.

Obe! jam facis el, 'lice libelle! Mart.

Ruribus, io, magnis clamat tibi Roma triumphus. Mart.

Quae ferebat ductor Sidonius, is.—Conslamentum. Sil. Ital.

In, veris caput, primum multofera amos. Propert.

Quae tua nume turgid quis Io freta longe reveras? Ovid.

Exspecta eum nonum morem utrumque Dianae. Mart.

Junus, Veius, Ceres, Diana, Minerva, Venus, Mars. Enn.

6. Aci, Diius, eheu, have the first syllable long.

Proximus eft ob illi levitate, locoque. Ovid.

IIlades: quas ipso decus fdi dier Camilla. Virg.

Eheu, quid volo minister! illius Autrum. Virg. &C.

7. In many Greek words a vowel is long, though immediately followed by another: as Achai, Achei- lous, Laertes, Laodic, and other words compounded with lco; Latous, Enyo, Panchaia, Thriecis, T Hgetus, Tros, Trout, Gathia, &c.

Eranth Mavros, avergadque rite Enos. Claud.

8. Those words which are written in Greek with the diphthong i, and in Latin with a single e or a, have that e or a long, as Aeneas, Museum, Darius, Thalas, Choi, Elephas, Orscades, &c.

It pacuca potosa, et Thesala centuriae. Lucan.

9. Most adjectives in ces, formed from Greek proper names, have the e long; and it continues so, when resolved into ei.

Oppida femo Peleusia mare vigeat. Claud.

Note.—1. Thoù which contain a diphthong ("ei") in the two syllables immediately preceding the penultimute, are more frequently formed, for the convenience of furnishing a diphthong, with the penultimute short; as Hecub, Neliorus, Antonius, Antoneruc, &c.

2. In imitation of the fpeech, we see in Status, the adjective Tiberialus.

10. Names of towns, temples, or monuments in ces, ius, or erus, formed in the Greek manner, from the proper names of persons, most commonly have the penultimute long; as Laodicia, Apamea, Carthai, Alexandria, Antiochia, M afololum.

Terrarum medius Apamea marius clara. Præ.

11. Academia, Chore, Platea, Malea, have the penultimute common.

In Latium Libera Academia migravit Athenia. Claud.

Poros furat plateau, nihil ut meditantibus obtet. Hor.

Aphirce per hincus plaus Romula fuscatur plateas. Prudent.

12. Greek genitives and accusatives from nominatives in ces have the penultimute short, according to the common dialect, only according to the Ionie.

Rionia petit centuri, levaeque hereditum. Virg.

Of Diphthongs.

3. A diphthong is long; as aerum,乏ncus, audic, subst, pantic, &c., long, until, Luces, luis, Gratias, Catus, Pompeius, Procurileus, &c.

Theocritus, ignotum argente pondos et auri. Virg.

1. Except pra, immediately before a vowel in a compound word, is generally short.

Nec tota tenac ille prior pre cupid naris. Virg.

Note.—Pre, originally being pra or pre, by the elision of the latter vowel before a following one, the words became preplus, pre- iument, &c. Status, however, (Theb. 6. 519.) and Sidonius Apollinaris (carm. 23.) prefer the e long.

2. A diphthong is often short in a line of Virgil, out of composition, thus,

Infudit Ionio in magno, qua di Seminar. Virg.

3. The ces of Greek proper names in ces (genitive eor) becomes a diphthong.

Paro dilexit spatio Minoa Thracas. Propert.

Conditus raimines arcanae mole Tyliscis. Lucan.

4. Yi is also a diphthong in Greek names, such as Orthiula, Illithya, Harpya, Agi, &c.

Orthiulaeanus fulvis amplecitari alis. Ovid.

Et parvo inmente Harpyias paleire regno. Virg.

A Vowel before two Consonants.

4. A vowel is long by position, when it immediately precedes two consonants, one or both of which being in the same word with it; as arma, Errabat silva in magna.

Pucre opertet ovar, reddat duplicare cernat. Virg.

5. Also, a vowel is long by position, when it immediately precedes a double consonant (X or Z), or the letter J; as axis, patrizo, cius.

At nobis, Per adus, venit, spectacum tento. Tibull.

It Stenobis, quos quod Mavroria vider Atropodus. V. Flacc.

Ca usa parceo non bona piper cit. Ovid.

Note.—In reality the J or Z makes a diphthong with the preceding vowel; viz., major, peor, are from maior, piier—and so in Maxim, Maxim, Briti, Troiae, Alas, enault, Cais, Caius, and Grail, ablative. Hujus and cius were, like illius, originally triflagites, of which the first two, by syneresis, coalesced into one.

Except the compounds of jugem, which have the i short before j; as bijius, quadrjugus.

Martis eia Hijys, et magnum currit Achillius. Virg.

Note.—The word which in English we pronounce jugum, is in reality I jugum or jugum, as the Germans at this day pronounce it. And in the meeting of two vowels, the former is tacitly elided, leaving the words jugum, quadrjugus.

6. If
6. If the former of two words end in a short vowel, and the next begin with two consonants or a double letter, the vowel often remains short.

Tuo poteris viriles penes hecatere molaregudos. Ovid. 
Jae medio appareat fluctu nemorosius Zygurus. Virg.

Note.—Virgil, however, who has adopted such licences as fuhris Hyacintho, and qui amant, has lengthened the short syllable but in one line; † Ferte citis ferrum, datel dedit, Eumidite mores. Many of these vowels, which at the end of a word are found long before two consonants beginning a following word, are lengthened by the author; as Occidetis sola, and plures de pace triumphos.' Juven.

Of a Vowel before a Mute and a Liquid.

7. A vowel naturally short, followed by a mute and a liquid, is common, though always pronounced short in prose: as agris, parcerta.

Natum ante ora paupertis, pateraque obstrucit ad ara. Virg.

Nec tenetras proboet, Phoebus fugat inde tenetras. Ovid.

Note.—1. To produce this kind of position, three things are requisite.
1. That the mute precede the liquid. 2. That the mute and the liquid be both in the following syllable; or otherwise this rule cannot take place; as in asulus, where the two consonants cannot be found in the latter syllable. 3. That the vowel preceding the mute and liquid be short by nature. Hence the a in acris and mattris is always long, because the a in acer and mater is always long.

2. In Latin words, l and r are the only liquids preceded by a vowel and a mute; in Greek words, l, r, and also m, n, have the same effect as Cyclopes, Te-mecisfta, Da-plane.

3. H is not, neither in this, nor the foregoing rule, to be deemed a consonant. Joined with any of the consonants, it has not the power of lengthening a preceding short vowel; nor even with two consonants (i.e. a mute and a liquid,) in the next syllable; as Dic Pellae us proboeff. Philipp.

Cernitur egregius laps hic, cui nomen abetates. Prsd.

Hic Philius myrto, hic purpureus amphilthys. Ovid.

Arbor habet frondes, pabula sperat humus. Ovid.

Of Crafts, or Contraction.

8. Every syllable formed by the contraction of two syllables into one, is long; as cogo for co-a-go, the genitive alius for allius.

Tityre esse pecus, tu pot certa latebas. Virg.

Obcura fretis patres amabilissim easse. Erat.

Note.—This is a rule of very extensive application. We are told that the ancients expressed a long syllable by a reduplication of the vowel; thus vixit for the perfect vexit. And it will be found that in many words the long syllable arises from the contraction of two syllables. Thus we write titican for titican; ambaeis for ambages; biceps, triceps, for biplices, triplices; junior for juvenior; bous for boubus; it for iit; mi for mihi; and mulo for magis volo.

Of Derivatives.

9. Derivatives usually follow the quantity of their primitives; as animus, anima, animal, animillis, animophus, animare; from lego; legem, legerem, legam, &c. but from legi; legeram, legerem, legero, &c. totalis from totus, and totus from tot.

Nec tuta pars, homo terrae quota totius unus. Lucret.

1. Except defferative verbs in aris, which have the a short, although formed from the participle in urus, that has a long; as nupturio from nupturis.

2. Frequentative verbs, formed from the second person of the first conjugation, by changing a into i, have the i short; as clamito, volito.

Pearl montes, naetor ridiculus mus. Hor.

In felix tua tecta super rotterato alis. Virg.

3. There are other long derivatives formed from short primitives, and short derivatives formed from long primitives.

Note.—1. Of the former, the following is nearly an accurate list; como from comis; femenis and fomentum from favo; hymenius from homus; jucundus and jumentum from juto; melibus from mero; regula from rego; regula from rebo; voto from voto; vox-voxibus from vox; dini from decem; tutpio from spina; sexus from sexus; penuria from penus; hurner from hurnus; jurtum from jutum; micerco from micer; place from plecso.

2. Of the latter, the following are the principals; arenis, areis from are; disces from dicis; differtus from diffis; ductis from dicis; fides from fida; friger and frigis from frango; lucerna from lucene; driso from disis; mixo from miso; nito from nito; nato from nato; promus and promba from nuto; quitius from quito; ritus from risius; abibus from abam; soror from soro; liquida and liquidal from liquides; sigis from sigos; videm from vide; arupes from atra; ambitus, ambitus, ambitio, from ambitus.

3. Some of these anomalies have, perhaps, arisen from the influence of the Greek and Oscan. Thus melibus from meosco, may have been mobiles; momentum, momentum; motum, motum; femum, femum; femur from foem; istum, istum; and jumentum, jumentum from juto. Sometimes the derivative becomes short by dropping one of the consonants which rendered the word whence it is formed to come, long by position; as differtus from dilfero; matmulis from mula; voltem from velo; solutum from solu; trigalum from trigal; patol from patim. When the primitive is unnecessarily short, by one vowel's preceding another, the derivative sometimes becomes long, by the addition of a consonant; as in hibernis, hiberno, hibernacula. Liquidus is supposed to have its first common (as it may be derived from the depenent liquor, or from the neuter liques,) on the following authority.

Cratique conveniant liquidis, et liquidae graffis. Lucret.

Compound Words.

10. Compound words have the same quantity as the simple words from which they are composed; as perlego from lego, perlego; perlego from legi; improrus from probus; perjuros from per and juro.

11. The quantity of the primitive word is generally preserved in the compound, notwithstanding the alteration of a vowel in the latter; thus accido from cadto, accido from cadto, acquiro from quero, queus, obliquus, antiquus from aquus.

Multa ramententur, quae jam cediderunt, cedentes. Hor.

Except 1. The following are short compounds from long primitives: nihilum from hilum; dejero and pejero from juryo; caudicibus, fatidicus, maldecus, veridicus, from disco; semiosopus from sopitus; cognitum and agnitionem from nootum; hodie from hoc die.

2. Imbécillius from baccillus has the second syllable long: comitium from numo has the a common.

Porto meo, nullo dextrae subestante baccilo. Juven.

Imbecillius, iners, & quid vis? adde pejor — Hor.

Cunabulo jugum irabilis, propriumque dacabo. Virg.

12. Prepositions, in composition, have generally the same quantity as out of it; thus ōmito and dedito have the first long, because a and d is, as a final and monosyllabic c are long. Aboleo and perimo have the first short, because ab and bér, as b and r final, are short.

Expediam, primâ repetens ab orignis, famam. Virg.
Nee poteris ferrum, nee edas ubolere venas. Ovid.

Note.—1. A preposition ending in a vowel, although out of composition, it may be long, becomes short by the first general rule, if followed by another vowel; as descelis, prohibeo. And if a short preposition ending in a consonant, and be followed by another consonant, it becomes long, by the second general rule; as ōmitto, pribeca.

2. Sometimes the preposition, instead of becoming long by position, leaves in final consonant, and remains short; as ōmito, opero.

Except 1. Di is short in dirimo and differtus: as Hane Dies et melior item natura dilectis. Ovid.

Caudo, inquis, agam Cicereon differtus ipso. Mart.
QUANTITY.

1. Pro is short; as rémitto, répello, référo. But re (which here is supposed to be the ablative of ret) is long in the imperfect verb réfère, it concerns.

Propellit Boraeus; alius et unde réfère. Ovid.
Præterea eum ut haurat pabula réfère. Virg.

13. Pro, when used as a Greek preposition for ante, is short; as prōphēta, prōlogus, prōpontis: but prō a Latin preposition, is generally long; as prōdō, prōveho, prōmitto.

Virg.[various]ubicunque theiæ Ovid, supposèd Hor.

Neapoli consider, Ovid, of but Ovid as the propagō, as anni of Mart. that Ovid; as (liort.) thus Thofe is the fometimes Hor. Captes in Greek as Alfo mnft is (hort. Mart.) introdiico, The Juven. Or

Note.—Notwithstanding such diſhinitions, propra, whose signification is always radiating the same, may be considered among the dooubt-able; to which elas procumo is likewise added by some. But when the remarkable irregularity of pro is considered, without the slightest apparent reason to determine why it should be short in one word, long in another, and common in a third, it seems most probable, that it was in reality everywhere where common, and that we should, doubtless, find it so, had we enough of the ancient poetry extant. The word being evidently borrowed from the Greek, in which it was written with an βίβλιον, we might for that reason expect to find it invariably short; but the Latin final o being in other cases more generally long, we might, on this account, as naturally expect to find pro usually made long, by those at least who were unacquainted with Greek. The poets seem to have avoided themselves of this convenient ambiguity by making pro long or short, as proved most feasible to their purpose.

Of the final Vowels of first Words in Composition.

14. If the first member of a Latin compound word end in A, that vowel is long; as trádo, trána, quaí, quaípropter, quæsumus: but in Greek compounds the A is sometimes short; as ἄδιππος, sometimes long, as Νέαπολις.

Except eādēm, unless it be the ablative.

Non eādēm arboribus pelest viandia nutris. Virg.

15. If the first member of a compound word terminate in e, that vowel is short; as in the final syllables of neáfas, néfandus, nēque, trédicem, trécenti; in the second of valediço, mádefácio, flüpēfácio, tremfácio; and in the third of hjufjucemódii, eujufémōdi.

Except 1. The E is long in words compounded of se for sex or for femi; as sédécim, fémeltri, fémmodi; (but in felifra it is short.)

2. It is long alfo in nēquis, -nēquīquam, nēquam, nēquitia, nēquando, vidēlicet, and venecius.

Nēquīquam term exreddit nōctu cantus. Virg.

3. Liquefacio, tepefacio, and patefacio, have the e of the second syllable chiefly short, though sometimes long: rarefacio and rarecho have the e generally long.

Ex: nem perpetuis ligamenti pectora culi. Ovid.

Tvī ligamenta, tendit is lēdor pulsa. Ovid.

Ex rarefactus calóris munito, vacēre, etc. Ovid.

Intraeckt, mutuoque tenēbat aquārum. Ovid.

Arte patefacto, quæ ante ob lectō atēr—

Note.—Vollus observes that Virgil shortens the e in such words, and that Lucretus and Catullus lengthen it, the former without cautel. Indeed it is probable that in these words it was generally considered common.

16. If the first member of a compound word terminate in e, that vowel is short; as bivium, trivium, treecip, siedquid, fatidicus, agricola, vaticinem, signifiço, architecutus, dimeter, trimeter, Iphigenia, &c.

Jane bivius annu tacite libenti origo. Ovid.

1. Except those compounds in which the i is changed in declining; as quidam, quisivis, quilibet, quantisivis, quantiuecumque, tantidem, unueique, eadem, republieque, qualiqueque.

Juve nihil invicem quies, ha te quoque amicum. Hor.

2. The final i is long in those compounds which may be separated without destroying the fene; as ludîmagister, or ludî magister; parvipedâ, or parvi pedâ; lucrfacio, or lucri facio; siquis, or si quis.

3. Those words which in joining undergo a crasis or syncope, are long; as thibien for thibien; bige, trige, &c. for bijige, trijige, &c.; ilicet for ire licet; licelicit for sine licet. but tubtecin, which has suffered neither, is short by the general rule.

Rerum ignis edax summa ad fallaciam vento. Virg.

4. Idem mafeuline is long; but in the neuter it is short. Identidem has the penultimate short.

Omnibus idem animus, fedetera exedere terræ. Virg.

Instar qui facrot, idem fact occidenti. Hor.

Qui fuedens aedexit identidem ei. Catul.

5. The final i of the former compound word, is long in miminur, ubique, utroboique, ibidem.

Dixi equidem et dico. Captus aetatis ubique. Hor.

6. As the i is common in ubi; so it is in ubicueque and ubivis.

Servum, ubicunque est: uni mea gratia servus. Ovid.

7. The compounds of dies have the final i of the first word long; as biduum, triduum, meridies, pridie, postridie.

Si solus ibi tribuo legatur. Mart.

Note.—1. Pridie and postridie are long by exception 3, being prior dies, and posterior dies.

2. Quotidie and quotidians are said to have the i sometimes short; but this is not satisfactorily ascertained, since the lines added in proof may, by the figure synizesis, be differently measured: thus Conjugis in culpa ·· bragavit quotidianās.*

Catul. * Or quotidiam-āvāt. It must be confessed, however, that thus read the line is harsh, and is unnecessarily rendered ··.

3. Triginta, triecipium, tridecim, tricenti, are not considered as compound words, in which the tri is short, as it is in all the real compounds of tri, víc, treecip, trítrítrí, tríecip, triecip, triencest, &c. &c. for triginta cannot with propriety be called a compound word, since ginta is only a termination. At all events the tri in triginta, &c. is ever long.

17. If the first member of a compound word terminate in o, it is short; as Argōnauta, Aréctophylax, areopagus, bibliotheca, philopothos, facerōfactus, duódecim, hōde.

Non nāce potus vos, sed Argoñautas. Mart.

Non dies hōdie, quārum hac tam paucis tandem—Hor.

1. Except words compounded with intrō, retro, contro, and quando; as intrōduco, intrōmitto, retrócedō, controverfus, quandōque, &c.; but quandōquidem has the o short.

Ipse retrōceó iudicium potest ad o. Ovid.

2. Allo aliōquin, utroque, exaterēquin, utroboique; and
QUANTITY.

and the compounds of quō: as quōmodo, quæcumque, quœminus, quœcīrqa, quœvīs, and quœque the adjecti;
but quōque, the particle, has the short.

Mendōs ad natura, aliique recta, velut il. — Hor.

3. Those words which in Greek are written with an
ο-nega, have the o long; as γεωμετρία, γεωγραφία, miniatūrus, lāgopus.

Si measurātī gaudēs lagōpōde Flaccus. — Mar.

18. U and Y terminating the first member of a compound
word, are short; as in Θρασύβουλος, Εὐρύπυλος, Πολύπυς, δακτύλιος, δυσπόδιος, κατάπτυχος, Τρομβίγενα,
corrupta, Πολύδωρος, Πολύχειμος, &c.

Nam fuit hoc virōs: in hora tāte dācuta— Hor.

Nam quis quintusque cavo Polypēnum in intro. — Virg.

Except jūdicō, which in its first syllable is, by syncope,
long.

Et tāpi, et mecum Lcit, et Jove jācēv, acqu. — Hor.

Of the first Syllable of Diffyllabic Preterites.

19. Preterites of two syllables have the first long; as
vēnī, vidi, vīcī.

Vēnit fūmās dies, et ineluctābile tempus. — Virg.

Except bibi, tāli, dēdī, Reti, Rīti, fctdī from scindo,
(for abscindi is long from abscido, and abscondī short
from abscindo,) fidi from Findo, (for Ridi and considi
from fido are long.)

Aut fēdīs, et medias fectūs libera terras. — Lucan.

Of the two first Syllables of Reduplicated Preterites.

20. Preterites doubling their first syllable, have that syllable
and the following both short; as tētīgi, pēpūli, pēpēri,
dīcīdi, tūdīdī from cade.

Si mēnīnt fuerant tibi quatuor, Ἐλξα, denter. — Mar.

Littera, qua cornu pādélti Saturni suinus equino. — Val. Flac.

Except ceōdi from cēdo has the second syllable long;
and likewise those preterites, in which that syllable
is followed by two consonants; as fēlīti, mō-
mōrdi, ṣpōpōndi.

Ebrīus et petulans, qui nullum forte coečīt. — Juvan.

...... Vatum śpōpōndit: nulla proper ma serco. — Senece.

Quae Deās ipse viris interamina foribus śpōpōndit. — Prud.

Note.—From the authorities here quoted, it is evident that śpōpōndi
is the elative orthography, not śpōpōndi, which would have the first
syllable long by position, before ṣp, as we may invariably observe
in compound words; as ṣpēnūs, ṣpēnū, ṣpēnū, ṣpēnū, ṣpēnū, ṣpēnū.

Of the first Syllable of Diffyllabic Supines.

21. Supines of two syllables, and the perfect participle
formed from them, have the first syllable long; as vīfum,
mōtum, bservable, lūfum, vitus, mōtus, &c.

Terribiles eʃa formae, letenque, lahorque. — Virg.

Quos ego — faecūs praetā concomere fācūs. — Virg.

1. Except the first syllable is short in dūtum, rūtum, fūtum, ìtum, lūtum, quītum, sītum, rūtum, and fūtum,
from the oblique fo, whence we have futūrus.

Cui dūtus harebrem culus, curficaque regebam. — Virg.

2. Cītum from cico of the second conjugation has the i short; but cītum from cico of the fourth conjugation
has it long.

Corripit cīse, et tečīs cīteus eŭtīt ali. — Virg.

Unde raunt tāx o concaeta percula mundu. — Lucan.

3. Statum is common: hence we find ñāturos,
confāturos, obtāturos, ñāmen, ñātus-um, ñātus-ūs,
Vol. XXIX.

praetūtum, ñātio, ñātuo, ñābilis, ñābulum, ñātor, ñātm,
&c.: the former of which are said to come from ño, the
latter from ñīto.

He ñātus in ōdio multos permansit in annis. — Ovid.

dānūs multο ñāturos amāne Martem. — Mart.

ßullūtor imperii, cuio famo os honorum. — Claud.

Non ñaetūs ñē ñatras natura solē usus. — Prop.

Conñūlens auri. Megalaus purpurea centum. — Mart.

Of the first Syllable of Polyfyllabic Preterites and Supines.

22. Preterites and supines of more than two syllables
have the same quantity in their first syllable as the preterit;
thus vōcari and vocātum have the first short, because the first
of vōco is short: clāmavi and clāmatum have the first long,
because the first of clāmo is long.

Si vōcāt officium turbā cedente velutum. — Juvan.

Induit, implerebat mero, divōte vōcāt. — Virg.

Except pōsui, pōsitum from pōnō; gēniī, gēnitum
from gignō; pōtui from potīum; sōlitum, sōlūtum
from solō and volō.

Saxula? quī tanti talem gēnēre parentes. — Virg.

Of the Penultimate of Polyfyllabic Supines.

23. Supines of more than two syllables, in ìtum, ìtum,
and ìtum, lengthen the last syllable but one; as amātum,
declētum, minūtum.

24. Supines in ìtum, from preterites in ìvi, also have the
penultimate long; as cupiūs, cupitūm, petiūs, petiūtum;
quēsīvi, quēsītum; poliūs, polītum; but the compounds
of co, ambo excepted, have the penultimate short.

25. Supines in ìtum, from any other preterites, shorten
the penultimate; as cubiūs, cubitūm; moniūs, monītum;
aboluūs, obolītum; agnovi, agnitum; creditūs: recensitum
of recensio is long, on account of its origin from the ob-
jective cenōs, cenīvi.

Namque servum fūtī Cœnō Paaesths amātis. — Virg.

Dōlēs Volcōrum acies, cœdider Caium. — Virg.

Saecula erētās vincula ad fidera palmās. — Virg.

Uplēs ineratūs prorās, gladiātī petiūs. — Claud.

Cedēmus Phoebō, et mōnēti meliora fæcūrī. — Virg.

Pēles recensitus evoluit fūcē latī. — Claud.

Of the Penultimate of Participles in RUS.

26. Participles in rus always lengthen the last syllable but
one; as amātīrus, habitūrus, lectūtus, auditūtus.

Tōrēs venit, fērīs fācērā nepōtībus umbram. — Virg.

Increment of Nouns.

Note.—1. If the genitive case singular do not contain a greater number
of syllables than the nominative, that noun has no increment, as
dēnis, dēnus, caro, carnis. But if the genitive contains more
syllables than the nominative, the penultimate of the genitive is the
increment; and whether that syllable be long or short, it preserves
the same quantity in all the oblique cases singular and plural. If
būbō or būbūs be an exception, we should recollect, it is so by syn-
cope and crafts from būvīus. Autōnus, contrary to the practice of
better authors, has an example of būbūs short, as if it had been
formed by simple syncope without crafts. See Aufon. Epig. 62.

2. Nouns seldom have more than one increse in the singular: et
Jesus, (when its genitive is jecinōra,) fupellēx, and the compounds
of caput, ending in ius, have two increments. The active and ablative
of the third declension have two; of the aforementioned
words, three increments. They are reckoned in the retrograde
order, beginning with the penultimate, for the last syllable is never
considered as an increment.

QUANTITY.

Of the Increments of the Singular Number.

Of the first, second, fourth, and fifth Declensions.

27. In the first, fourth, and fifth declensions, there is no increment in the singular; except the antique increment of the first declension, by the resolution of the diphthong & into ai, in which the a is long; as

Dives equans, dives pietatis velis et auri. Varg.

28. The increments of the second declension are short: as

pueri, viri, faturi, tenieri.

Oueri! ne tana animis affligaste bella. Varg.

Except Iber, Iberis, and its compounds Celtiber, Celtiberi, which lengthen the penultimate; as

* Increments of the third Declension.

29. Nouns in A shorten the genitive penultimate; as dogma-atis.

Non quiis idem immutat poena judex. Hor.

30. Nouns in I, compounds of meli, shorten the genitive penultimate; as hydromelici, hydromelitis.

31. Nouns in O, increasing ininis, shorten the genitive penultimate; as cardo, cardinalis; imago, imaginis.

32. Enis and onis, from o, are long; as anio, anicing; sermo, sermonis.

1. Except gentiles in generally shorten the increment; as Macedo, Macedonis; Saxo, Saxonis. To which add Lingones, Scounes, Teutones, Vangiones, Vafiones. Some lengthen the penultimate; as Subeiones, Vetttones, Burgundiones, Eburones. Juvenal shortens Britones; Martial lengths it.

2. Nouns in ae, from the Greek, which sometimes drop the n, preserve in Latin the same quantity which they have in the original; as Agamemnon or Agamemo, Agamemnonis; Demophon or Demopho, Demophilis.

Sanguis phlebas venas, etinge ceras. Virg.

Quae nec terrilibies Cirbri, nec Brittonum unquam— Juven.

Quam veteres brevitas Britonum: pauperis et quam— Mart.

Quo seris judice petit Agamemnonis. Ovid.

33. Nouns in EC lengthen the genitive penultimate; as halec-ecis.

Halecob fed quam protinus ipsa vort. Mart.

34. Nouns in D shorten the genitive penultimate; as David, Davidis.

Erecto inducet Davidis origine lumen. Juven.

Note.—Ecclesiastical writers often lengthen the penultimate of David.

35. Masculines in AL shorten the genitive penultimate; as Hannibalalis; fal-alias (masculine or neuter).

36. Neuters in AL lengthen alias; as animal-alias.

Vasa debeat loric, et sanae silex veri relict. Virg.

Pomum comque pingue assidue caro terra. Ovid.

37. SOL lengths alias; and also Hebrew nouns in EL lengthen the genitive penultimate; as Daniel-ecis.

Regia siles cras felibus alias columnis. Ovid.

38. All other nouns in L shorten the genitive increment; as vigil-aliis, confu-lalis, exul-aliis.

Aut ursum, aut fugilis, ha min plebeius pudet. Hor.

39. Nouns in EN shorten the genitive penultimate; as criminals-inis, flumen-inis.

Quocumque magis mirum el, auditores crimenis hujus— Mart.

40. No certain rule can be given for the quantity of the increment of nouns ending in ON. Many lengthen the genitive penultimate; as Chiron, Demophon, Agon, Helicon, Lacon, Seycon, Simon: many shorten it; as Actaeon, Agamenmon, Amazon, Jaron, Memnon, Philomen, Orion, Sidon, Simon: and Egeon has the penultimate common.

Credit, et exclusit ianos Heliaca poetas. Hor.

Et velut aitente certamin Allequina elamant. Ovid.

Aegaeo duros lautanem Aegaeon nexus. Ovid.

*Adogaeonius in immanis terga lucertis. Ovid.

41. All other nouns in N lengthen the genitive penultimate; thus Titan-aris, Siren-ecis, delphin-inis, Phorcycnis.

Conicit iratus validos Titanes in armis. Ovid. Hor.

Orphus in sylios, inter delphinus Asis. Virg.

42. Neuter nouns in AR lengthen the genitive in ariis; as calcari-aris.

Seu fumantis eique foleret calcari-ecis armis. Virg.

But these neuters shorten ariis; bacchar, jubar, consectetur-aris. To which add par-paeris, and its compounds; as impar-imparis, dilipar-disparis, etc.; also hepar-atis.

Pugnavere pares; succubuerue pares. Mart.

43. But masculine nouns in AR shorten ariis; as Cæsari-aris, Hamilar-aris, lar-laris.

Etce Dionis prorectis Cæsaris alnum. Virg.

Except Car and Nar; as,

Laudus immodicus Circes in alta fertat. Mart.

Sulures potuit siprimas Naris ad undas. Enn.

44. Greek nouns in TER lengthen the increment; as crater-eris, character-eris, spinther-eris; except ether-eris.

Indulgent vino, et vertunt craterer-eris. Virg.

Quaequeque illis lemen fuissent facta etherei pennis. Virg.

45. Nouns in OR lengthen oris; as amor-oris; timor-oris.

1. Except neuter nouns; as marmor, sequor-oris.

2. Greek nouns in OR; as Hecotor, rhetor-eris.

3. Arbor-eris, and memor-remeris.

4. Ador forms adoris or adonis, whence adores in Virgil, Horace, and Claudian.

5. Except neuter nouns; as marmor, sequor-oris.

6. Greek nouns in OR; as Hecotor, rhetor-eris.

7. Arbor-eris, and memor-remeris.

8. Ador forms adoris or adonis, whence adores in Virgil, Horace, and Claudian.

46. The following nouns lengthen the increment; fur-furis, ver-veris, Recimer-Recimieris, Byzer-Byzzeris, Sers-Seris, Iber-Iberis, (as well as Iber of the second declension.)

Volfenque ut falsis desipit templa Sers. Virg.

47. Other nouns in R, not mentioned, shorten the genitive penultimate; as aer, aetris; mulier, ceris; cadaver-eris; iter, itineris; verbis, verbis; vultur, ariis; murmum, uris; furor, jecur, ebur-eris; martyr-yris.

Si nigrum oblunio comprehendit irea corna. Virg.

Alpere, venti recteundit murmurera auro. Virg.

48. Latin nouns in AS lengthen the increment; as pietas-atis; Maccenas-atis; vas, vasis, a vesel.

Insigne pietatis virum tot adire Libores. Virg.

Except
QUANTITY.

Except anas, anatis; mas, maris; and vas, vadiis, a
security.

Tyrraёмque marès animalis in martia bella. Hor.

40. Greek nouns in AS shorten ádis, átis, and ánisis; as
Pallas, lampas, ádis; artocreas, átis; Melas, ánisis.

In hac montis equum divina Palladis sorte.

50. Nouns in ES shorten the increment; as miles, militis;
seges, segatis; praefes, praesidis; obies, obidis; Ceres,
Ceréris; pes, pédis.

Maturis fer quemque suo modulo ac pédé, verum et. Hor.

Except locuples, quies, manifes, étis; heres, mer-
cos, édis: alfo Greek nouns which have étis; as
lebes, Thales, tapes, magnes, étis.

Africanum furgentem, et ípes harbélis Iuli. Virg.

51. Nouns in IS shorten the increment; as lapis, Phyllis,
idis; cinis, éris; fanguis, insis.

Immatet et ponam federe ex fangúle fumis. Virg.

1. Except glis, gálris, and vires the plural of vis,
which lengthen the increment.

Sonnícululos ille porriqüis glítres. Mart.

Sic fatus validis ingentem viribus faétam— Virg.

2. Latin nouns which have ítis, as dis, dtítis; lis,
ltítis; Quíris, Samnis, ítis; but Charís, a Greek
noun, has Charítis short.

Inqueque tenan hunc, et Íte mararis iniqua. Hor.

Tres fuerant Carolis, fed dura mea Lothia vixte— Aufin.

3. Crenis, Crenidis; Nefis, Nessidis; Pfolpis, Pfo-
phidis, lengthen the penultimate; but Pfolpis shortens
it once in Statius.

Sylvaque, que faxam pelago Nesída coronat. Stat.

Úfque sub Orcheinomena, Ófphídiqale Cylenénque. Ovíd.

4. Greek nouns in ís, which also the termina-
in; as Salamen, or Salamin-ínis.

Tiburis umbra tui, Teucer Salamína pærenique. Hor.

52. Nouns in OS lengthen the increment; as nepos,
ótis; flos, flóris; os, óris; cuftos, cuftódis; rhinoceros, ótis;
Tros, óis; heros, óis.

Qui legítis fórtes, et humi axcentia fraga. Virg.

Égregií stipét, pectantur Trós arcu. Virg.

Except bos, bónis; comos, impos, ótis; which in-
crease short.

Perpetui tergo bónis, et luftraibus exís. Virg.

53. Nouns in US shorten the increment; as lepus, corpus,
órís; velúss, éris; tripus, ódís.

Ut canis in vacuo lúpém cum Gallicíis arvo. Ovíd.

1. Except those nouns which have udis, urís, or
uítis; as incus, incúdis; tellus, tellúris; falsus, falsútis.
But these are short; Ligúris, from Ligur or Lígus;
pecúdis, from the obfolète pecus; and intercúdis, from
intercus.

In medit: facri trípódes virideaque corona— Virg.

Pax et Írás fancit: rivos deducere nullum— Virg.

Non ego te Ligúram duxor fortissime bello— Virg.

2. Comparatives in mé lengthen the genitive pen-
ultimate; as melius, melóriás.

Perge, decer, farum mísceás melióra sequantur. Virg.

54. Nouns in YS shorten the increment ydís and ydós,
and lengthens ynís; as chlamys, ydí or ydós; Tráchys,
ynís.

In medio, chlamýde, et píctis conféctus in armis. Virg.

Herculis Tráchýne jubes, sub imagine règis. Ovíd.

55. Nouns in S, preceded by a consonant, shorten their
increment; as celebs, ibís; ítlps, ítís; Lælops, ápis;
Cecrops, Dolops, ópis; aucups, cúpis; hiemis, ónis; also
anceps, biceps, cípitis, and similar compounds of caput,
in which both increments are short.

Ad matres primo uncipites, oculitique malignis— Virg.

Hic Dólipum manus, hic favus tendebat Achilles. Ovíd.

Except Cyclops, òpis; féps, fépis; gryps, ýphís;
Cecrops, ópis; plebs, píebis; hydrops, ópis; and
genitives long by position; as excors, excords, pars,
parts.

Fortunam, et nates antique plélés, et idem— Hor.

Antiphates memores immutabilis Cyclopis. Ovíd.

56. Nouns in T shorten the penultimate of ítis; as
caput, ítis; fúcicup, fúcicípitis; occípit, occípitis.

Magna fuit quondam capitis reverentia cani. Ovíd.

57. A noun in X shortens the vowel before gís; as har-
pax, ágís; gres, grégís; aquilex, lègis; biturix, ígis; Styx,
ygís; Allobroíx, ògis; conjuç, ògis; Phryx, ýgis.

Quinde grégès ills balantum, quina redibant. Virg.

Ad Ægesta Ténariæ et natus decendere porti. Ovíd.

Except lex, lègis; illex, exlex, lègis; rex, règis;
coccyx, ýgis; maltfav, ígis; and frugís, from the
obfolète frux.

Omnia fúb lèges mors vocat atra fux. Ovíd.

58. A noun in EX shortens ícis; as vertex, ícis; pon-
tíexus, ícis; ícis; vibex (rather vibix), ícis excepted.

Qualem virgíneo deeme fúllce fórem— Virg.

59. But EX having ícis, lengthens the increment; as
vervex, écis.

Verúscum in patria, crastíque sub ære naci. Juvén.

Except nevé, nécís, vicís, and précís, wanting nomi-
natives; also facníex; reflex, écis; and supplexus, éctílis.

Quam vicés artificis are porie fua. Ovíd.

60. And all other nouns in X generally lengthen the
increment; thus nouns in as; as pax, pícis; formax, ácis.

Except abax, smílaq, Atrax, dropax, fáx, Atna,
climax, panax, opponax, flýras, colax; the com-
 pounds of phyllax and korax; as Areóphyllax, Nomó-
phyllax, nycticorax, phalacrocórax, icís.

Fraterque fidem pácem petítuque díntaque. Ovíd.

Diasa fílices animae tuque, optimae vates.

61. Thus words in IX; as radix, felix, cicatrices, nutrix,
viétex, altrix, perdix, coturnix, pernix, lodix, icís.

1. Except appendix, chónix, coxendix, cílix, calix,
formix, fílix, hlírix, larix, pix, félix; varix, ícis, and
flírix, flírigís.

2. Nix, nísis; maltfax, íchis, a gym.

Eccé coturníce inter tua praemia vivant. Ovíd.

Et fílice curvaevis in fímad pácifam arátas. Virg.

Et flírigís inventa per butia jacta pluma. Propert.

Jam fatís terris nívia atque dixér. Hor.

Contritumque simul cum màstico confert amethum. Seren. Summ.
62. And words in OX; as vox, vocis; velox, oecis. Except Cappadox; precos, oecis.
63. In UX; as lux, lucis; Pollux, lucis. Except dux, crux, nux, trux-lucis.
64. In YX; as bombyx, yecis. Except onyx, ychis; Eryx, yecis; calyx, yecis; Naryx, yecis. But Sandyx and Bexyhx have the increment common.
Nec sequa Abaricio lucet bombyxque puella. Illaque plebem, vel le faniiciis amitut. Propert.
Of the Increments of the Plural Number.
65. The plural increments, A, E, O, are long; as musarum, ambibus, animabas; rërum, rebus, hörum, quorum, regnorum.
Tuque, bïrum intreperc curium, et conicia, Juno. Virg.
Scollet in nobis rërum natura mutata est. Ovid.
Rébus in adquid facile est contemnce vitam. Mart.
66. The plural increments I and U are short; as quibus, tribus, montibus, vertibus, facibus.
Except hibus or hóbus, which, on account of its contraction from sóvibus, as already explained, is long.
Necre tribus nodis ternos, Amarylli, colorés. Virg.
Non opibus mones hominum curaque levantur. Tibull.
Pars in frutus locum, verba quæque trenuentes locunt. Virg.
Cunm fæber edcit, lactues demittit: at ilidum — Ovid.
Et totum libert curvatis arcibus orbem. Manili.
Et Tiberis nostris advena ñobis orat. Propert.
Increment of Verbs.
Note—1. When any part of a verb exceeds, in the number of syllables, the second person singular of the indicative present, active, the exceë is considered as the increment. As in nous, the last syllable is never reckoned the increment; so allo in verbs; and, therefore, when there is only one increrae, it must be the pro-

2. Thus amat, amant, ama, amem, amans, containing, like amam, cally two syllables, have no increment. A-mam, a-mam, a-tis, a-ci, a-res, a-mam, have one increment, because they ex-
ceed, by one syllable, amas, fies, ñis, and was. A-mam-mas, a-ma-tis, have two increments, because they exceed amas.
A-mam-mam-mam has three increments. A-

3. But in any other increment do, like its compounds of the third conjugation, is long; as dábamus, dederitis, circumdábamus, cedamus.

67. A is long in the increments of verbs; as flábam, ñàres, properámus, docebámus, audiebámus.
Serius aut cibus fedem properamus ad unam. Ovid.
Papiláriam armis, qual se fábricaverat aúos. Hor.
Et condore pares, et repindere patriis. Virg.
Cunctamplorat stem, cun té nas pluris filios. Ovid.
Except that do, and its compounds of the first conjugation, have a short in their first increment; as damus, dóbam, dåré; fi circumdámus, venundabó, &c. But
Section II.—On the quantity of the penultimate and antepenultimate syllables, and on the quantity of such as are usually said to be long or short by authority.

Note.—It is very well known that the profodul rules, hitherto esteem'd, determine not the quantity of every syllable of the Latin language; but of such only as are more commonly aftenom'd from the circumstances of position, division, preterites, futuris, transirets, and final coniunctives. For in the smaller number of instances, the inquiries of the student are at a stand until he can appeal to that observation, which would be more happily employed in confirming his previous acquisitions. And this with but partial instead of complete information, he arrives to the same results, the truth of his prejumt, at the time when he unquestionably might achieve the secohd, the satisfactory and practical illustration of his previous attainments. If we depend on practice for the best principles of our knowledge, we live its belt and happiest effect. Practice will always advance its most prevalent efficacy, when its office is alone to refer the superstructure on the base of regular syntax and theory, and not to attempt the casual and fortuitous talk of laying a tranitory foundation, and that too on a vacuum, the baseless texture of ignorance, not admitting that analogy and arrangement, that reciprocal and corroborative illustration, which to essonally aid the intellectual faculty with its true and permanent improvement. The part which follows is an attempt to supply this defciency. It was obtained by four consecutive analyses of the language, in which every word and syllable poised under minute and decisive consideration. This investigation was undertaken in conformance of its being suspected, that since it is a general rule in the predlty of the Latin language, that a vowel before two consonants, &c. is long, that a law exists, directly the reverse of this, and of not less extensive influence; viz. that a vowel before a single consonant is short: though each of these general and very extensive rules, may have, in special cases, their exceptions. The result justified the expectation and proved, that principally with the addition of another general rule, the profodural system might become comprehensive, as to include and provide for the whole language; and consequently, for all those syllables usually said to be long or short only by authority. The exceptions to this general principle are chiefly included in the rules for the penultimate and antepenultimate syllables. And though some of these have appeared in former treatires, yet from their enlargement, the addition of others, the general rule, and its more special exceptions, which have arisen from the repeated analysis we have undertaken, it will be easy to perceive, that we have in this part some claim to originality. In the preceding rules, and in such as shall follow on final syllables, in justice to the subject and our readers, we have felt it indispensably incumbent on us to avail ourselves of the valuable researches of preceding and contemporary preoducing. And the originality of this section places us under the obligation of devoting our attention to the most demonstrative part, that every rule and exception, which we now first offer, might not appear to rest on our bare assertion, but on the only legitimate warrant, poetic function. And thus, perhaps, we have now the opportunity, for the first time, of offering the only complete collection or system which determines the quantity of every syllable, at least of pure and Augustan Latin, that has hitherto been presented to the public.

1. Masculine patronymics in ades or iber usually shorten the penultimate; as Prasides, Atlantides.

Atque his praisiudum lamarum corpora teneo. Virg. En. 6. 494.

1. Except those formed from nouns in sus; as Pelides.

2. Amphiaraiides Naupiaca Aceheko. Ovid. Fab. 2. 43.

5. Quinque Lycurgides fictus, et arboru nauum. Ovid. in lb. 525.

2. Patronymics and similar words in airs, erys, and ertis, lengthen the penultimate; as Achais, Ptolemais, Chryseseis, Anes, Minos, and Latios.

Except 'Thebaie and 'Phocais: 'Neris is common.

1. The-
Words ending in *icus, idus, and iudus, short the penultimatum; as *Egyptiacus, *aromaticus, *callidus.

2. Allo *nudus, *sideus; *fidos, infudus; but *pervidus (from *per and *fido), follows the general rule.

3. Words ending in *imus or *ymus, shorten the penultimatum.

4. Thus animus, decimus, firmus, ocimum, anonyrnum, callionymus, and all adjectives and superlatives in *imus shorten the penultimatum.

5. *Teleuten quotunque meridius repertor uus.

6. Continui moxet, nulli教授urca optica.

7. Effi magnus, Thelefine, vestis anunus —

8. Ducere apricus in collibus uis colorum.

9. Et tu facies in fronte integriter crines —

10. Cum me fucus at, cum parca dulcibus uvs.

11. Nec mendicus far barbati prandi udi.

12. Ocupit caco, puiffe occurrit fannuz.

13. Perdi poterit tam frugi tamque pudeus.

15. Et tu patruus cumbna, cum pulcros uae.

16. Ore furat, ducem sitis inuitatus ecan.

18. Fortunata donus, modo sit fibus animus.

19. Diffimulare etiam ipedis, profilo tanurus.

20. And two superlatives, *imus and *primus.

21. Tum vitulos, binae curvum, jam cornua fronte.

22. *Limus ut hic durecit, huc ut his cere licefast.

23. Scribere hic et illas imitantur terror mus.

25. Deponio quadrinum Sabina.

26. Ex summae aestimatur sime virgulta cappella.

27. Quae, velut lati eis quam campano campis —

Note. — The quantity of the penultimatum of patrinus and matrinus is indeterminate: Faciolatus, the Italian lexicographer, says "lis ut inter grammaticos de quantitate eorum penultimatus, quae adhae est ubi juvace, qui habet certi adhuc potequendum.

5. Other vowels before final *mus or *num are long; as ramus, rémus, pónum, dünus.

So amonnum, cámus, cardamónum, cinnamónum, dénum, extrémus, fiumus, grúmus, hámus, pótrémus, prónus, raceónus, suprémus, volémus.

Syllepses: rare spuit labrca racina.

2. And words ending in *drenus, from the Greek *dronos; as epidromus, homodromus.

1. Parvum ferie conflant connum *áthormus.

2. & 3. Bulánnum qui fesum, cinnamónum sere fempor érret.

4. Non aequum gravis sé dénum mili dexta redit.

5. Ut vindus fínum convivus Pyrrhia laru.

7. Æásius, Albaneum nes, te pyáma prdes.

8. Pot ubi jam fhalémis te composuere, filetur.

6. A vowel before final *le, *lie, or *ile, is long; as mone, amánis, mêles.

So ancel, bovile, bùle, caprile, cr. ile, fócule, fæne, ile, incile, mantèle, manitile, omile.

And âles, anulis, aprílis, civille, cardéulines, curúlis, crándes, conúgalis, dotali, exitis, fidelles, herilis, miles, patriélius, proles, quinétilles, stubtiles, estéllis, fectilis, &c. with many others.

1. Et opportunum se bovili condidit.

2. At qui umbrata gerunt civilci tempora quercus.

1. Except *verbaal nouns or adjectives; as agilis, amabilis, facilis, insile, misfilis, misfile, utilis.

2. And all adjectives in *atilis; as aquatilis, fluviatilis, plicatilis, voltatilis.

Note. — The penultimatum in Poliénus, Afincoth, as well as every other author, which is long. Faciolatus, however, gives this quantity, as derived from多方, a tree, it certainly should have.

7. Adjectives in *imus derived from nouns signifying *trees, *plants, and *stones; also from *adverbs of time, or from subjunctives signifying the four seons of the year, shorten the penultimatum; as faginus, hyacinthinus, adamanthius, craflius, diutinus, perendinus, cimerinuus, annotiuns, hortinotus: to which add bombyculus, elephantinus, which seem rather to refer to the silk and ivory, than to the animals themselves.

1. Trudit et sico radix oleaginis ligno.

2. Grandia tolluntur crysallina, maxima ruribus.

3. Mvrhinus, deinde damas notatimus.

4. Et lux cum pinnem terras et crinis reddet.

5. Delicias et panicibus bombyclicus unit.

1. Inque repentinus convivis verba tumulat.

2. Motulina parum catuum jam frigores modest.

3. Nec sejprinus circumcederius ovile.

Note. — The penultimatum of malinus, Afincoth, as well as every other author, which is long. Faciolatus, however, gives this quantity, as derived from malius, a tree, it certainly should have.

8. All other adjectives and words ending in *imus lengthen the penultimatum; as caninus, bimas, trimus, feminus, Latinus, mediafinus.

Vix primus luxigina quiex laesurus arsus.

1. Suadebat Amsn fuga, ne potest capi.

3. Tum caput ipsi affert dominus, tamuncumque relinququit.

6. Quicumque mundi terminus obtinet.

9. Other vowels before final *mus and *num are long; as urbánus, plèanus, domum, múnum.

So ahénus, fánum, prénus, prünus, férénus, vènum,
Quant. numeral, and other numerals in eni; fo finis, ascinis, inclinis, inanis, communis, immotis, communis, immotis, &c.

2. Bis sinu Iatro taximus robore naves. Virg.
4. O curas hominum! O quantum est in rebus minae! Peri.

Except 'bene, sine, 'pene, 'cenis, 'cinis, 'ju-venis; and nouns derived from materia, as hippocrines, trichomanes.

1. Visur parvo bene, cui paterum— Hor.
5. For 'cenis, 'ese veri 3. under the above rule. Hor.
7. Hippomanes, quod farpex male legere nocever. Hor.

14. A vowel before final 'nea, 'neta, 'nia, 'nina, 'nus, and 'num, is long; as linea, cano, mino, pino, favo, ferminium.

So aranea, ganeo, declino, delineo, linea, cicione, insania, Iriona, colonia, alcedo, lacrima, quermionia, deloxio, extinxio, fino, insania, minio, confinium, patrimonium, vadimonium, and many others.

1. in foribus luxos sustinet artibus caelis. Virg.
5. Primo restitute vere Faustio. Hor.

3. Quam finis? Aut quod me munit stipendium. Hor.
4. Inclinita minent in eadem prassa partem. Lucret.
5. Aliquid moneat, ut illa, quae se creas, nocescas. Ter.
7. Multa gemens, ignunam, plagae superbi. Ovid.
10. Quin lument mundum; tanta et discordia fratrum. Hor.
11. Momento cito mors venit, aut victoria ieta. Hor.

15. A vowel before final do is long; as vado, cedo, for- mido, rudo, tefludo.

So rado, credo, alcedo, culcado, cupidio, crepido, nodo, cudo, ludo, altitudo, beatiudo, and many others; for the nouns and verbs comprised by this rule are very numerous.

Posse putas illos fcco freta rudder paulli. Ovid.

Except 'cado, 'divido, 'trepido; and 'rudo, which is common; and 'edo, to eat: edo, to declare, public, &c. (the preposition 'e being long) follows the above rule.

1. Multi renfentur, que jam cecciones, cedenturque. Hor.
5. Inclusumque causo fuso, atque infesta rudentur. Virg.
6. Ut vero expia certis quies; futur arder edendi. Ovid.

16. E before final rust, ra, rum, is short; as murus, be- dera, catenum.

The nouns and adjectives comprised by this rule are numerous.

Ite domum fature, venit Hebestitus, ite capella. Virg.
Cerum est, in sylvis, inter spicis faram. Virg.

1. Except
QUANTITY.

1. Except "auterus, galerus, iplerusque, sērus, fevērus, vērus; pērā, cēra, and sēncerus, from fine cēra.

2. And though of anthēra, aenōthēra, flatēra, there is no poetic function, they are long by derivation from othēra, ἀνθῆρα, et genēra, fo panthera (Virg. Æn. 8. 460.) from 4ēra.

17. Other vowels before final rūs, rūm, are long; as cărūs, mīrūs, mōrus, mūrus; hārā, fōrā, orā, natūra, lūrūm, &c.

So værā, rārā, rārā, hōrā, àrrōrā, lārā, māntīcōra, prōrā, captūrā, figūra, censūra; also the nouns, adjectives, and participles in rūs, &c. are very numerous.

2. Vela legunt fōci, et prāsās ad littera torquent. Ovid.
3. Puniceo tendenti mūnē color.

1. Except "barbārus, cammārūs, camūrūs, canthērūs, chōrus, hellebōrus, īnīrūs, oppīpus, sōvārūs, iērūs, Tartarūs, tōrūs. Ovid.

3. And the following in rūm; "forum, "suppārum, 25 gārum, 2 pārum. Ovid.

4. And the "compounds of vērā, as carnivōrās, omnīvōrās; those ending in "phōrās and "phārās, from 4ēgēs, as amphōrās, caephōrās, ephēphōrās, phsphōrās, ecbiltōphōrās, &c.; and the derivatives of 4ēgēs, as hydrāgēs, lithārgyōs.

20. Words ending in "atūs, "atūs, "atūs, "atūs, lengthen the penultimate; as probātus, cētus, tōtus, tūtus.

So grātus, faciōs, bólices, póteros, argūtus, aētītus, brūtus, hircūtus, mytus, and many others; also participles in "atūs, "atūs, "atūs, and "atūs, as mandātus, decretātus, nōtus, minutus, metātus, constrictātus, volātus, &c.

1. O fortunātus nimium, fui sī bona mortātus!
3. Facēr omnes, cum valorem, reēt conās, cēgōs, damārōs.
4. Tūtā māntēs; mediis Tānāvēs fumāvit in undās.

1. Except "cātūs, "lātūs-ēris, "fātūs-ūs; "impētus, "mētus, "vētus; and "antīdōtus.

2. "Venētus is short by derivation from Venētīs; "quōtus from quōt; "tōtus (fo great), from tōt, for tōtus is long; and "arbitūs from arbor-ārōris.

3. Of dicētūs, and automatūs from automatōn, there is no poetic authority.

4. Except the plural genitives of nouns ending in ma-mātis; as poeta-ma.

5. And the participles dātus, rātus, sātus, fātus; for which see the rule concerning dissyllabic fuses.

1. Me ēbus fātus quam vīr, dédērīm volōs cōnsumīrātum. Plaut.
3. Erēs in vērōbōrum tūnūm cēplūnum in me et fātīsum. Plaut.
4. Ēquārā; ec illum fēt impētūs iēple volantem. Virg.
5. Norōm ētīlō dolor, ìdēm ēgōs miōs inuctā amēn. Lucan.
8. Sēs fecēttās ëllōs, ëllōs, Britēsus Britannīus.

9. nec ētīlō nos rumam terram, quīēlās tōtūs unūs. Lucrat.
10. Inferiōr verō ex fētīs nācīs arītus horridā. Virg.
11. Words ending in itus lengthen the penultimate; as aurītus, crīnītus, invitātus, perītus.

Fac ēm tu, praece, nunc omnen aurītus populam. Plaut.

1. Except
2. Allo *all adverbs in *ita; as humanitus, penitus.
3. *Blitum is not derived from the termination *itus, but from *beta, and therefore shortens the penultimate.
4. *Aplly polyphallic participles in *itus, not derived from preterites in *i; as habitus, exercitus-a-um, and nouns derived from them; as habitus-ās, and exer- citus-ās.
5. And the participles from the verb eo, and its compounds; as transitus-a-um, and their derivatives; as transitus-ās; the participle ambitus is, however, long, and the noun ambitus-ās short.

12. Dena perpegnim minimus *cend研究表明.
QUANTITY.

3. Except alio "verbs in ulo or uer, which are generally derived from diminutives in ulus; as circuleo, circulare, from circulus.
1. Tuitus et geminos aitiam mater dicit.
2. Et color extremus primo cum frigore mistus.
3. Mille tribus varios adverbio sole color.
4. Filla uccum, trivago gerunt in bella uffices.
5. Materiemque diabeto, levare sc traduce tigam.
7. Molestus uque in pittus; vampullandum; habendus
9. Cætere; alteres Muses meminem viueant.
10. Irenem Trojanum, et Velut eòdit Alba monorem.
11. Et color vagos indutis abest amnis.
12. Utique; id oro te, in commune ut consiliis.
13. Vec Papes spectare perit; volubilique gignit.
15. Lift superbus ambulas pecud.

Note.—Antievst has tombbo, which should be bembont. See Facibus.

27. A vowel before final 'ber and *ger is long; as nubis, ambages.

So labes, tabes, pubes, compages, impages, ftrages, fruges, &c.
1. Sub pedibus uietis addes et tidera Daphnis.
2. Jan evertum dat fimenque uqui agent ipsas.

Excep 'des, *indiges, 'leber, *seges, and *tages.
1. Utique 'beret pecus tantummodo contulit iebi.
2. Dii patris indiges et Romane Vellaque mater.
3. Terris dona fact gemina ex pia libet.
4. Illa siles demum votis respondeat avari.
5. Initial hyberus *tibiis, nivique cadere.

28. A vowel before final 'des and *pers is short; as fides, tapes.

So analesides, anterides, hydes, pleides, sudes, and all mafecule patronymics, according to the first rule; so allo aperes, daypes, tripes, and the following compounds of pes, bipes, tripes, quadripes, centipes, antipodes, ceripes, graciles, alipes, levipes, fupipes, cornipes, ignipes, longipes, loripes, palipes, foidipes, exrapes, &c.
2. Infratras uito alpedes periquic *tibiis.

1. And though we are without poetic authority for caretudes, caiudes, horminodes, yet their penultimate is evidently long from the Greek a; so epides; as aper; *sper, *axiodes, *gemines, *frenides.
1. Clesbuses usitum nocturneque præcium arma.
2. Doct ad infernas per multa fletia aedes.
3. Illi, velut pelagi rupes immensa refinit.
4. 'Exendix ripes citam, et præm unce tenendum est.
5. *Splebitus duum adhibet 'rubricque praecur.

Note.—The classical evidence of triades feoms not to be satisfactorily proved: Ainworth and Facibus cite one authority, Tert. Ann. 1. 49, where commentators propose sudes, as a better reading.

29. A vowel before final 'dex, *dex, *lex, *mex, *nix, or *rex, is long; as codex, radix, lex, cimex, jumex, carex.

1. Hade poex ad petaue, acque ad robustum cedem.
2. Praebat ab aereis ecosse redeo reminus.
3. Prudentum prece, sacra ista facturis idex.

4. Cui demus et doles latebro do pumices vidii.
5. Quam mon horrum ad flabrum jades recipiat fe ac

6. Et Calamum cosit vixitio miror velut.

Except 'culix, *silex, and *rumex.

1. Tota abit hora. Maii cihes, ranque palutes.
2. Spem gregis, ah! *silex in nudis comnis requit.
3. Apponunt 'rumices, brasiliam, betam, bluim.

Note.—Alex, in the book authors and editions, is read idee, and is therefore no exception to this rule.

30. A vowel before final 'per and *ter is short; as siper, arbiter.

So per, caper, ter, later, accipiter, diameters, patre, Jupiter, Diospiter, and all adverbs in ter; as atlas, ampler, acrifer, celerer, and many others.

1. Dum juga montis ipper, fluvius dam pisces, amabit.
2. Non locus efflu late maris arbiter, aufer.

2. Uter-trata-trum follows the general rule; but 'uter-tris, a bag, lengthens the penultimate.
3. Alto 'soner from sero, of which the poets give no example, except through its derivative soteria.

1. None haec refulit nuper ad me epicodom.
2. Calebs inimicitie dimitter ad in uram.
3. Cui velut, importumus ebor; frater, pater, addes.
4. Cui mater mede facit ultima olyva.
5. Tum patre Anchises magnus celeris coronis.
6. Nam diceronis omnes femes licentia.
7. Fater ut immunda comis abire odor.
8. Mochus in parte unius faler per odes.
9. Nam quoque furgis, siteras peces amicos.

1. Liquitur, et Zephyro patris et globus tecum.
2. Linquium, infant riderces praxima fera.
3. Sumum materiam vestris, qui feraebis aequam.
5. Ilu abante, et illis ducere caedem haec lux jubet.
7. Cedenda est horcis erato cæpa mea.
8. Hac tobi brumulad gesture frigore râpa.
10. Qui hac legitum condili, et data ocello est, rapi, &c.

Note.—Cûpa, 'râpa, et 'pâpa, are sometimes more properly spelled cupa, fluppa, papua; since this latter orthography designates their quantity, and is more convenient with their derivation from vox (Venus cuppe), *sper, &c. Cûpa and cêpo seem corrupted readings for cupa, which the more accurate editors substitute.

32. A vowel before final 'ga is long; as ëgaga.

So argula, biga, quadriga, collea, saga, pyga, rûga, fanguiga, folipiga, &c.

At Novis coligae gradu pul me fedo uo.

Except 'caliga, 'offiragra, 'tûga, and the 'derivatives of fûga, as fûga, perfûga, lucifûga, lucri-fûga.
33. A vowel before final go is long; as inago, origo, infigo.

So aringo, urigo, aurigo, furigo, compago, cartilago, confiligo, caligo, figo, sigo, keperfigo, sigo, suffrago, &c.

Adjectrice meae, primaeque ab origine mundi.

1. Except 'ego', 'fago', 'harpago', 'ligo' (noun or verb), 'rego', 'figo', 'vigo', 'strico', 'telo'.
2. Allo 'congrego' is short, from grex-gregis; and 'jugo', from jugum.

3. Lego-are of the third conjugation shortens the penultimate; but lego-are, of the first, lengthens it.
4. Except allo 'ago', and its 'compounds; as nogo, navigo, litigo, mitigo, &c. It is to be observed, however, that when the 'compounded' has been formed by ynceo or carminis, the penultimate, according to the rule for contracted syllables, becomes long; as fatigo, from fatum or affatin and ago; nado, from indo and ago; farrago, from farre and ago; vertigo, from vertendo and ago; calfigo, from catium and ago; dago, from de and ago, &c.

2. Trans pontum fugit et terris immittit apries. Virg.
4. Longis purpure golvus aura. Ovid.
5. Difhola levis concordi pace fugavit. Ovid.
7. Prata fugit his interdum, campiique redundat. Latrec.
8. Sacerdos, id faecat; atque aqua hinc de proximo rigo.
15. Hor etiam fevas paffam nattitum iras.

34. A vowel before final 'gu', 'gum', or 'giam', is short; as pelagus, jugum, navigium.

So alpargus, catalagus, confirgus, naufragus, olftragus, dialogus, epilagus, ethlagus, eligrus, lucifugus, indigus, conclugus, mages, magus, the noun sages or sagem; conjugium, elogium, fortellegium, naufragium, prodigium, diffagium, perfigium, horugium, remigium, facrillegium, aquillegium, confegium, &c.

Materiae tanto in pelago, turbulente aliena?

1. Except 'fagus', 'fragum', 'frigus', 'pagus', and the adjective 'sagus'.
2. Allo 'contagium', 'faltigium', 'uffragium', 'vetigium'.
3. And 'choragus', 'choragium from ɔχρος', 'χρος'; &c. &c.; and 'pedagigus from ɔυς'.

14. Libera si dentur populo fageira, quis tam, &c.

35. A vowel before final 'a', 'e', 'i', 'o', 'u', 'ae', 'ae', is long; as clava, proclive, dives, civis, pavo, rivus.

So cea, conviva, diva, gingiva, pava, prærogativa, uva, xilva, oliva, conclave, nève, clavis, fulvis, názis, rávis, acelvis, declivis, proclives, vivo, pravo, rivo, nivo, privo, xilvo, ilvis, ignávis, xilvis, divum, óvum, právis, and all adjectives ending in 'uus', which are numerous.

2. Currere per tumum prudens felicem magisque. Hor.
3. Divis aetas, dives politos in feram nummis. Hor.
5. Ubereas os, silent virtutis, eleusico fecundar. Virg.

1. Except 'avis', 'brevis', 'gravis', 'levis', 'ovis'.
2. Allo 'cavo', 'gravo', 'juvo', 'lavo', 'levo', 'novo'.

36. A vowel before final 'a' is long; as ipica, forica, fullica.

So antica, apica, cloaca, carrùca, currucca, erica, mica, myrica, lactuca, lectica, noctilucia, rica, rubrica, loricca, pica, patina, phoca, fambica, sita, urtica, vetica, &c.; and several ending in 'eca, from as apotheca, bibliotheca, oropotheca, &c.

Parena nam exemplo est, magni fornicar laboris. Hor.

Except 'alica', 'brazica', 'fulica', 'mantica', 'perrica', 'tunica', 'falarica or phalarica', 'dica.

1. Nos aliam, nullam poterit tibi metteriore dives. Mart.
4. Monetica cui labios ancora utere, atque aequares. Hor.
5. Perticem dat plenis inquit vulnere ranis. Ovid.

Note.—1. Aphasia is rather aphasia-ae from ἀφύαι, and therefore does not relate to this rule.
2. And since adjectives in 'ica' shorten the penultimate; wherever the termination 'ica' is derivable from an adjective in 'icu', though the adjective itself be not in 'icu', the penultimate is short by derivation as: 

Piraeus from piraticus; i.e. as pirato piraticum.

Fabrica from fabricus; i.e. as officina fabri fabrica.

Flaminia from flaminus; i.e. as flamina flaminica.

Manica from manus; i.e. as vetus manica.

Pedicula from pedicul; i.e. as cutana pediculosa.

Lucanica from Lucianicus; i.e. as Laciumber lucanica.

Bucidae from bucolicus; i.e. as carmina bucolica.

Basilica from basilicus; i.e. as ult. basilicas basilicul vel basilica.

Arithematica from arithmeticus; i.e. as τινης άριθμητική.

Memoriae from memorialis; i.e. as τινης μνήμη.
37. Words ending in 'aris or 'are lengthen the penultimate; as alaris, altaere.

So agricultura, peculiaria, naris, arceare, capillare, plantare, quiare, and many others.

1. Suisicus, partius capitalis narius aurus.

2. Suisicus except us latum plantarius horst.

Except biliarius, bimarius, cantharius, capparius, mare, and dare.

1. Oderant bilhiare tribus, tribunique peculi.

2. Ant Ephidius bimius Cottarius.

3. Cantharius facies, dante parentis, bibis.

5. Ante mare et tellus, et quod rogat omnia eadem.

6. Sec. for dare, the verbal is accentuated.

So cruella, carduellis, patuellis, candelé, loquella, quercella, corrupetula, cicendela, clientela, maidella, eterella, Philemela, parallellus, polyemelis, areuwis, fulces, formelis, futoce, perneucis, nidas, cridas, lidus, and many others.

1. Numquam et fidelis cum potentia societas.

2. Et erat puella venlora turra phelis.

3. Quisqu publicae morum Phebus stab umbra.

6. Quod Nero tam xevia, erat que tyrainde fecit?

Hic hilar fa rey enem fronta tur ad aureas.

8. Nee fales faet; siutis tamen est fepia.

— Her.

39. Words ending in 'uber, 'uber, or 'aver, lengthen the penultimate; as October, faluber, vapaver.

So fuber, tuber, uber, uber, tuber, cadaver, &c.

1. Te beae, Octuber fenet dixit agnos.

2. Quique frequent herbes et ferulis orbere campus.

3. Lilla purpureis mille paupaver.

Except coluber and ruber.

1. Inque prunulo coluber differentiar ino.

2. Crime ruber, uiger ore, brevis pede, inactive larus.

Mart.

40. Adverbs in 'im lengthen the penultimate; as oppidatum, viriditum, tributum; except statim.

1. Et velut absentee est et causae, Actuum clamat.

2. Nec sparsit aeris, nec tamen erat etat.

Phaed.

41. Words ending in final quae are compounded with quas, and therefore lengthen the penultimate; as antiques, inquires, obliquus.

Terra antiquus, poena amis atque ubert gelse.

Verg.

Except religius, which is not derived from aqua, and is therefore excepted.

1. Exsatur religius trica palata tuba.

Mart.

Note.—Though the real cause of the penultimate of inquiis, antiques, &c, laying long, is the contraction of the e, of inquiis, from which they are derived, into i, which is therefore long, according to the rule, we have given another contraction; yet more the above may be a more obvious distinction than a Latin cause, we have not thought it improper to add it. And since this remark is applicable to some other terminations and examples, occurred in this analysis, it is sufficiently here, once for all, to give this general notice.

42. Words ending in poli, or pelium, being derived from polius, lengthen the vowel before l; as bibliopola, cenophilum.

So myropola, myropomum, propola, pharmacopola, &c.

1. Sed qui me vendit Bibliopola potat.

Plaut.

2. Nam omnes pleras percepserunt, gymnas et myropola.

Plaut.

43. Words ending in 'ares, 'ares, 'uarius, 'uarius, 'uarius lengthen the antepenultimate; as parco, cibarius, acerarium, meliorum.

So aro, clereo, hordarium, stium, librum, mercurarium, herbarium, capitulum, dicarium, cecilarium, nectarium, phalerarium, adulatorium, cenarium, and many others.

1. Yno gemmim feuit, poteque incerta duibus.

Ovid.

2. In hinc diem iam tus sum mercurios.

Plaut.

3. Omnibus arbilis, diciera dicis in omnes.

Mart.

4. Quem es eram mi neo ferio.

Mart.

1. Except clereo, varius, and nectareus, from nectar-aris.

2. Allo defidarium, from defidéro, magitarium, from magit, and minitialium, from minifit.

3. And the derivatives of genitives increasing in short oris, as aquorius, arborius, caloreus, corporeus, choroerous, marmoreus, lercorius, roborum, from aquor-iris, orbor-iris, cator-iris, corpus-iris, choro-iris, marmor-iris, lercor-iris, robor-iris.

4. Except allo fome derives from o (omereon), as boreus, anthorbeus, hyperboreus, from sigeis.

1. Silect et maribus, defidare corvis.

Juv.

2. Et aures aquis, melius aquaeris.

Verg.

3. Ancis ituribus utibus melis famem.

Verg.

4. Roma, domumque sed, defidaremqve locorum.

Ovid.

5. Viante, id factum, ut, et magifero tuo.

Ovid.

6. Fels magistarius mineus, reparata lboris.

Ovid.

7. Arborer frondes uno radiante nixitis.

Ovid.

8. Vos posuas patria pergantis sab ace Ercia.

Ovid.

44. Words ending in 'aeris, 'aerius, 'aeret, 'aerius, 'aerius, 'aerius, 'aerius, lengthen the antepenultimate; as tellaece, ciferius, subfuerius, aheneus, idoneus.

So arenaceus, hederaceus, hordaceus, refinaeac, ceteriu, araeus, conditeius, rejeceius, collectacius, bipedanius, and many others.

1. Hedora strome acericeus terra.

Var.

2. Ficus et irrigus, pone effer eth annius arbii.

Verg.

3. Nee nebulas nevus, necene arantius semitula fals.

Luctet.

Hor.

5. Opponeris ne at fesse et indicene.

Luctet.

1. Except cattaneus, from cattanea.

Cattaneocyis nices, mores Anaaris annanat.

Verg.

45. Words ending in icus, icium, or icus, shorten the antepenultimate; as patricius, edificium, ealditium.

Patricius omnes opibus eam provocat unus.

So gentilicius, tribuniciius, adventicius, fæcitius, aulicius, judicium, artificium, arulicius, maleficium, beneficium, officium, extulicium, harrulicium, fecricium, indicium, officium, paneficium, and many others.

1. Except novicius, or novitius; and those which come from long sapines; as effrutitis, from eflitius, ire, ivi, itum.

2. Allo coticivium, licium, and nutricium, from nutric-icis.

1. Jam fecer in ripa tertumque nubibus heret.

Juv.

2. Nunc in me dolce contrahere lyre lingue.

Ovid.

3. Et prosellos, damnsare boves, et trina tela.

Verg.

4. Ostiumque infiamat matri nutrici turbas.

Mond.

46. Words
QUANTITY.

46. Words ending in 'aticus, 'atilis, 'etudo, 'atis, 'uito, lengthen the antepenultimate; as aqt挤ticus, aqtqilis, valçtudo, secrinatio, locutio.

So pluvialis, pliucalis, defunctudo, crematio, balbunio, and many others.

1. Calceola pedis, noscibilis aquaticus Aucter. Ovid. 2. Labiur oculat, fallacique colatima ris. Plaut. 3. Gratia, fama, vallfscco contagious ambiata. Hor. 4. Seclolia nee raa aed. impa ebi habitatio. Plaut. 5. Badioctum securum, praxat lausum male vulnus. Hor. 6. Except some ending in milticus, from neuters in mii-ali; as aromaticum, from aromaticum; rheumaticum, from piqiarites; grammaticum, from eajo-pqaroites; and hepaticum, from hepaticis.

Grammaticum animile tribus, et pilica digito. Hor. 7. Abilis lengthens the antepenultimate; so does bilis, when from long preterites in ivi; otherwise it shortens it, as ambilis; expetibilis, from expetio, itiv, itum; terribilis, from terreo, ivi, itum.

Accipiam, euclidiqué meum lotabilis actu. Virg. Terribilis squalor; qui prius mesto—Plaut. 8. Abulum, 'callum, ecula, lengthen the antepenultimate; iculum, icula, shorten it; as pabulum, gubernaculum, apècula, ridiculus, curricula.

1. Pilibe pra legegns, miliqilque lequebus aedes. Virg. 2. Omnis transformat bebo in meculam terum. Hor. 3. Aut urum, aut pugile, ibis nain pleclrodeo genet. Hor. 4. Quem ex horre'scido contundas iunrere. 1. 8. 12. 3. 4. 5. 

Humannus genus est avidum minus australclut. Lucert. 5. Except 'periculum, and 'some long by derivation; as haceldum, from hedile; rediepointulc, from redieo, ivi, &c.; loricula, from loricis, pollculcum, from politkis; nutricula, from nutrieulc. 6. Sed tibi vestrum per modus periculam vitre. Prop. 7. Et unice manubis et habent rediecula utie mira. Virg. 8. Words ending in 'tulum, 'dilus, 'fertilis, lengthen the antepenultimate; as mendacium, pittacium, contumelia, multifurtum.

1. Impreduta per mendaciu virende labum. Ovid. 2. Quod quins indicatam conti contumelia. Plaut. 3. Ut diarhium bibi non hic ile. vivam. Plaut.

50. Numerals ending in 'ius, lengthen the penultimate; in 'gintis, 'qintis, 'gires, and 'fintis, the antepenultimate; as bini, sini, viceni, deceni, viginti, octoginta, nonagies, octogies, vigesimus, multiesimus.

So quinque, septeni, octo, novem, undeni, duoden, tredecen, &c.; quadrangins, quinquaginta, &c.; quatercentina, quadragesimus, &c.; quateragesimus, vigintosim, multiesimus.

51. Words ending in 'ates, 'ites, 'ites, 'eta, and 'eta, lengthen the penultimate; as vates, vitiis, catyotis, diotia, meta.

So crites, penates, mitis, chalectis, pleuritis, amplitis, arthritis, capitis, mephitis, cariotca, ecrorisa, bêtes, créta, cosmetis, contems, poeta, secta, &c.

52. Lastly; the following final syllables lengthen the preceding vowel; 'nur, 'cal, 'gal, 'ral, and 'tal; as laciti, pulvinar, cervicis, vectigal, Bacchana, munita, and some others.

53. Allo, whatever terminations are naturally derivable from any of the preceding final syllables, lengthen or shorten, according to their primitive termination, their penultimate, or antepenultimate syllable; as mascelines ending in 'arisus, may form feminines in 'aria, and neuters in 'arien; fo 'aribus, 'aria, 'arium; 'etis, 'eta, 'etum, &c. as 'ararius, belonging to copper or brass; 'araxis, a copper mine; 'ararium, a treasury; hence rosarium, pomarium, mufcarium, meridarium, quercetum, rosctum, palmctum, &c.

Note.—1. And it should be recollected, that since compounds and derivatives follow the quantity of their primitives, the compounds and derivatives of such words as form exceptions to any of their rules, will follow the general rule for the quantity of derivative words. 2. And it may be here necessary, finally, to remind the young student of the time rule, since the quantity of many vowels is explicable fully by this law, and requires no other direction; as additious from additio; algesiculns from aliens; contraclis from contrarius; altheimotes from aliquis, &c. Hence adjectives ending in 'eas-'eas form derivatives in 'eas-'eas, as exas 'eas, exas 'eas, exas 'eas, exas 'eas, in the same manner genetives increasing short, shorten the corresponding vowel of the derivative; as carislaginis, carislaginum, carislaginosus. Thus preterites and supines having their penultimate long, lengthen accordingly the derivative vowel; as dormito from dorminio-'eas; condito, conditos from condito-'eas; fo condito, conditos, conditor from condididion 'eas; hence arantes, arantes, audito, audito, et exes 'eas-'eas, &c. Thus words ending in 'als may form derivatives in 'als, 'als, 'eter, 'alts, 'alts; hence cercals, ecartiligenus, carislaginosus, arantes, audito, et exes 'eas-'eas, &c. Hence words ending in 'als have their derivatives in 'als; as 'albus,'albus, 'albus, 'albus, 'albus, &c.
QUANTITY.

55. Y before or after R, is long; as Butyrum, collyrium, papyrus.

4. And the derivatives of 'pyrus; as hydragyrus, lithargyrus.

3. See the 3d exception to the last rule.

1. Et lacrymis furgunt ranuntius ora genueph. Lucret.
2. Sit mbi Musyra toler, et cantor Apollo. Hor.
3. Neve inter veres corrylum fere; neve flegia. Virg.
4. Ebrias incintis philrylaeora capillis. Ovid.
5. Inre he nuce, Nibiliae, pyrus sine ordine vites. Virg.

At vero Zephyrus cum luna vacatis visis—

56. U before or after R, is long; as bruidus, бро., ruumor.

1. Neplies bruma slis innsufrurgris. Hor.
2. Quæ ves ad ulis omeris rannre uncundo. Hor.

2. Except allo i inter 'generis, increasing short in 'isus or 'iris, and their derivatives; as crux-crucis, trux-tricus, augur-uris, murmurur-is, sulphurur-is, which give crucio, tricidio, mürmuö, augurium, sulphureus, and the like.

3. Alto, 'meditative in 'ura and 'luxurio; as 'saurio,
" other verbs in urio follow the general rule; as ligurio, facturio.

4. U before final r, and r following by a vowel, are regulated by the rules for those circumstances; as augur, factur, ruo.

1. Pretor adeo vacueque loco effossi uritus. Lucan.
7. Et manquum querellis eceus doloris accret. Ovid.
8. Quem flaxico Chareis 1110d habendo quadam. Hor.
15. Vultus in unum me frutes. Hor.
17. Tractavit celeme manibus, dum parata libit. Hor.

57. 'O and 'U, before m are long; as vómer, bátmalus.

1. Ingerente, et solvm atrites utente fere vincer. Plaut.
2. Quale solé sfysis briandati fugacé viícac. Plaut.
3. Except to before m,'cómata, 'cómedo, 'ómitto, 'tómaculum.

2. Ato álmos, domus, glómus, tómus (for which see sec. 2, rule 2); coma, chores (for which see sec. 2, rule 23); dòmo, homó, and vómo; (for which see sec. 2, rule 25.)
4. Alto, columna, documentum, molinum, tr-

gümen (for which see sec. 2, rule 22); humus, postulmus (for which see sec. 2, rule 5); cucumis (for which see sec. 2, rule 23); and autum (for which see sec. 2, rule 25.)

5. For circunceto and cercitame, see the rule for 'm final.

1. Quod sum velt, homo, crinemam fili de colla dissolute. Plaut.
2. Exannimatum in códum omnium in spectus sustinere asse. Lucan.

58. U before e is long; as búcui, dico, caducus.

Adveegabo aites rœs, et tétu caduce. Prop.

2. And in 'generis increasing short in'isus, and their derivatives; as dux-dux, crux-ducis, trux-ducis; hence crucio, tricidio, &c.

1. Quod puré tranquillo; hómen, au ducce licellum— Hor.
3. M. Hic est, nequeque jubet, ducceque phlactatas. Mart.

59. Syllables indifferently spelt with one or two confoants are long; as litera or litero, litus or litus, cupa or cuppa, püpa or puppa, flüpa or fluppa, fícroma or fícrom, flópus or flòopus or flóopus, cólphium or cólphium, which should invariably retain the double confoant, since it is by position alone that they are long, by the confoant, and not by the word, reduplication.

60. Syllables indifferently spelt with a single vowel, or a diphthong, are long; as teda or teda, prélum or prelum, which latter orthography, the most expressive of the vowel quantity, it is better to retain.

61. Vowels derived from r, s, t, s, are long, as hircús, silus, músa, from ἄρης, στῆς, μῦς, μῦδος.

Note.—Many of these are already compiled under the preceding rules; the principal words referable alone to this rule, are cetum, creta, hépar, hépero, lechus, lechum, lichen, àde, ñetor, flepsul, flepsules, þéatons, ñer, ñeris, ñother. To these we may add over 200 words of very rare occurrence, chiefly signifying plants, herbs, flòes, minerals, &c. &c. as ambrosias, alicypus, aphelon, &c. Of these we would here insert our manuscript list, but since they are principally confined to such authors as Pliny, Celsus, Tertius, and Frontinus, they are matter rather of occasional reference, than of any grammatical rule.

62. Some words alike in orthography, differ in quantity only according to their signification; as

1. Populus aor
2. Efi; notar et populus
3. Plèbem, Silus aës ët pro
4. Prae; nequeque plum
5. Numa; melina melina
6. Stripes intimate pollin.
7. Melis; excticum duplum;
8. Mela; ponum.
9. Facitis paláide; et ñeré
10. Stagnum hészpe; at non tamén díc.
11. Plátos notán swind. Nitor, ninedfque,
12. Prosthenque ater et melinaeque,
13. Ab eo swind. Plágas notáce
14. Retis etraæ corrputit; licet
15. Venéris aut vice vulneris, tu
16. Extremita; in plágem.
17. Centralitapalis; rale
18. Denotari, por rage pñlum; nmne auge pilus
19. Aceti ferem àulique;
20. Ex pilum quoque, mallumque d;on.
24. Citelre apuros arc dicemus; id led colora oris, fana.

Note.
QUANTITY.

Note.—The above verbs not only furnish the words relating to rule 62, but also, to unite two objects in one; they at the same time afford a specimen of all the Horatian metrical, which, to the classical student, may prove a useful compendium. The following is probably, only the second production of the kind in print. The first is quoted by the two editors of Horace, Cruquius and Buxtorf, and, had its fulget been as eligible as the design, the present would have been superseded. For a definition of the Horatian metres composing this specimen, the reader may consult L convinced of Horace, Livy's Libri Poeticos, (ed. 17th. p. 242.) or VERSIFICATION, in the sequel of this work. The following, however, are the Horatian metres, as exemplified in the above lines: 1. An Adonic; 2. A dactylic pentameter; 3. A Pheroean tripodia; 4. A Glyconic choriambus; 5. Dactyle tetrameter; 6. An hemistichus; 7. Lambechus ae duplo; 8. Iambic dimeter; 9. Lambic decamerataetieca; 10. Lambic trimeter tetradactyle; 11. Lambic trimeter; 12. An aulidian; 13. A Sapphie hendecasyllabic; 14. A great Alcaic; 15. A small Alcaic; 16. Alcaic choriamboc; 17. Choriambic dimension; 18. Epelicuriametric tetrameter; 19. Ionic trimeter hexameter; 20. Sapphie line; 21. Ionic a minor tetrameter; 22. Dactyle hexameter; 23. Fifth elegiacal Archilochian; 24. Second elegiacal Archilochian. The remaining words alluded to by rule 61, are comprised by the following hexameters.

General Rule.

65. A vowel before a fingle confonant, not affected by any preceding or following rule, is short; as sapio, siliqua, graciillitas.

Note.—To confine the preceding rules to limits as short as possible, 17, the preceding rules and their exceptions relate only to words of pure or Augustinian Latin. 2. Some terms of very rare occurrence, chiefly the names of plants, herbs, flowers, folios, &c. near 500 in number, are omitted, as matters of occasional reference, rather than of constant attention or grammatical rule.

2. We have now, after four confluent analyses of the language, for the more complete information of the student, accomplished a task, perhaps never achieved before, nor, so far as we are acquainted, offered to the public, in any profuse system. And we can venture to affirm, that any words so acquired, compared with common proedly, and the rules of this definition, will not, within the precedents of Augustinian Latin, find a single word, except the few of rare and unfrequent occurrence mentioned above, whose quantity is not regulated or accounted for by the rules now given. Thus, for the first time, we have reduced that, the majority of Latin quantity, by all preceding probations referred to a course of observation and practice alone, to a regular classification and system. Would our limits permit, we would here, for the sake of explanation, take the words compiled by any letter of the alphabet, and account for the quantity of each by the principles and exceptions we have here considered.

3. It is almost necessary here to add, that the quantities of syllables are marked with very frequent inaccuracy in most of our common dictionaries. The poete are the only satisfactory tell.

SECTION III.—On final Syllables.

1. A final, in words declined by cafes, is short; as fama, regna, lampada. Anhore de prora fulce: tant littere puppues.

Virt.

1. Except the ablative singular of the first declension; as lice, musu, hoe aenea.

2. The vocative singular from Greek nouns in as; as O Polli, O Atli.

Virt.

Non hec, O Polli, dederas profius parent; Virt.

2. A final, in words not declined by cafes, is long; as ama, ulrire, praeterea.

Virt.

2. Littus, mania, et lera, brizant fine palpulae coeunt. Virt.

2. Incorritis many nuceri matrure pantos. Virt.

2. Except iti and eia short, and poetæ common.

Virt.

2. Quin is generally short, but since Phadrus lengthens it, we may pronounce it to be common.

3. Some profudians quote puta, with the short, from Perius, 4. 9. But the well editions have puta, a reading evidently preferable, in point both of sense and grammar.

3. Though numerals in ginta are sometmes found short, approved authors lengthen the as; yet it may well to recollection, that the Greek termination KONTA, whence the Latin ginta is evidently borrowed, has the final vowel short; as

Tas V apue retucha KONTA µai̇naus eis ilvros. Hom. [See many other instances in lliad B.]

QUANTITY.

3. E final is short; as nate, patre,jure, nempe, ante.

1. Except that final E in all cases of the 1st and 2d declension, is long; as Calliope, Tydides, Anchises, Æneas, also famé, originally of the 5th. Thus also, rēs, istic, and their compounds quārē, hōdē, priōrē, postōrē, quotidiēnē.

2. Alto in all nouns wanting the singular; e.g. cētē, melē, tempē, pelagē, Greek neuter plural.

3. The second person singular of the imperative of the 3rd declension, has the E long; as doce, mont; but cae, vale, vide, respondē, and 4th, have e common.

4. Monophthongs ending in E are long; as, me, tē, nē, nē (leat or not) except 4th and 5th, and ordinary adjectives; as, quē, tē, pē, rīs, lōs, as neque, quōque, fuātē, ē pocum, tēte, &c.

5. Adverbs in e coming from nouns of the second declension are long; as placē, pulchē, valide, or validē, &c. Except when bene, malē, superē, inferē, magē.

6. Ferē, 'fere, and ohē, have e long.

1. Hanc tuam Peneophen lesto tibi mitis, Ulyssēs.

2. Et quamquam tibi pariter raptōque, Peneophen.

3. Quæ meæ e hôdere, cur eam nec non iuicerit?

4. At pelagē melē, et late fulmenta videamus.

5. Vade, rēs, carē na timēre, manēsque, tēsque, ēs, lōs, &c.

6. Inde, quod non ēst, factum, rēs dicere fāltem.

7. Repōnē, quibus amīllis separae quaeque res.

8. Si quando veniet? dicet; repōnē, postā.

9. Quōd idātae vinum, nisi quodque decoris ipse.

10. Pārēs, ne dubio, cumque compurgam tibi.

[See all Por. I. 187.]

12. Salēs, pares haeger nobilis undā.

13. Vera, inquit; neque me Argulīa a gente negābo.

14. Pencē, cum ēmāteō trabēābus contesctō acernā.

15. Nō bene cum facies, fās atque omnēs homēs.

17. Mobēs et varia e,f erae natura mārum.

18. Anque feri, fido, fabulae littōre puppēs.

19. Imperātūm, amīt Ludērī? det is etis eam.

I. Final is long; as dominī, chafis, fieri, doceri, audī, i. Ilii.

Off respondet rex Albae Longās. Enn.

1. Except the i of Greek vocatives: as Alexi, Amaryllī, Thētī, Pāri, Daphni; but Simōi, or such as belong to nouns having etsas in the genitive, are long.

2. Greek dative singular of the third declension, from nouns increasing, are varied. Minōiōi and Tēthi in Catullus, and Palladi in "Statius, are short. Thētīdī in Catullus, and Parīdī and Tyndarīdī in Propertius, are long; but Greek dative formed by contraction are always long; as Demosthenēs, metamorphōs: also those which come from the first declension in Greek: as Orellī, Euripīdī.

3. Nuntiōs in i are also short; as umbri, melī, fāmplī.

4. Datives and ablative plural of Greek nouns in i (in before a vowel) are short: as hero, Trasō.

5. Mīhi, tībi, ubi are common. Allo ibi, nīhi, ubi and quā. but thesē hār are more frequently short.

*Note. — These may be long by poetic license, or by position; for the i of Greek cases, is naturally short. Orphē may be considered as a dative in Virgil, Ecl. 4, 551; and by Lucrētīs, it is a dative in the Georgēs, 4, 533 and 553.
1. *Indi manu validas poës est moderanter habebas.*
2. *Nimic quemque rapidi contra confidere leones.*

7. Y final is short; as *Moly, Tiphys, Chelys, Tethys.*

*Moly vacant superi.*

Except when y is a contraction, as in Tethys, instead of Tethyi, the dative, it is long by the general rule for crasis.

Quam Tethy longiusque dies, Glaucocyope repollan. *Val. Plac.*

8. Latin words ending in B shorten the preceding vowel; foreign words lengthen it, as ab, ob, Job, Jacob.

Magma ob integro faciorem mataitur orda. *Virg.*

9. Final C lengthens the preceding vowel; as ac, sic, hic, (adverb), dic, illuc, &c.

Sc sedulus, sic ille manus, sic as ferocet.

1. Except that nec and donec are short, as allo the imperative fac.*

2. Hic and hoc of the nominative and accusative, are common.

* Two passages quoted from incorrect copies of Ovid, to prove for long, in better editions appear *facie and face*; so that, according to the opinion of Alvarez, it is safer to consider fac as short.

1. Parve, nec immo, fine me, liber ibis in urbem. *Ovid.*

10. Final D, in Latin words, shortens the preceding vowel; in foreign words it lengthens it; as quid, ad, apud, illud, sed, David.

 Ips decet quid agam. Fas eft et ibi hodie doceri. *Ovid.*

11. Final L shortens the preceding vowel: as mel, fcl, pol, fimil, femel, nihil, consul.

I nocui variant: *procul hinc, procul impius eft.* *Ovid.*

1. Except that Hebrew words are generally long; as David, Nabat, Saul.
2. Sol, fol, and nil, are long.

1. Non aut, oxymorum extrae.
2. Ommia sub pedibus, quas aut utrumque recurrens. *Stat.*
3. Nil opus externae cupiens, nil indigas laudis. *Claud.*

12. Final M was, anciently, short, and was not, as now, elided when followed by a vowel.

Ingigna feri tum millia miliim odo. *Enn.*

13. It is short in circum, in composition with words beginning with a vowel, as *circumene,* *circumige.*

13. Final N lengthens the preceding vowel; as en, splen, quin, non, sin, ror, Pan, Salami, Orion, Titan.

Meret et ardentem Orim aurum ignis. *Manil.*

4. Allo an, in, forsa, forritan, tamen, attamen, veruntamen, vide, fatin, have no short.

1. Addunt et titulum; titulus breve carmine habebas. *Ovid.*
2. Naudhab ant claram Bhuton, aut Milaen. *Hor.*
3. Tantaque nos animi eft, ibi hic accedisse, dixit. *Virg.*

14. Final R shortens the preceding vowel; as vir, puér, tére, timo, calcul, Hamilcar, anamur, audiuntur.

Tun poter omnipotens missa perfregit Olympum. *Ovid.*

1. Except 1 Greek nouns, and 2 such as have eric, long in the genitive; as crater, Ratér, vér, Recimér, Iber-eris; but Celtiber, the compound of Iber, has the penultimate common.

2. Allo hic and eter, though they increase short in the genitive.

3. And ñ, far, lár, nár, 11 cùr, 11 for, and 11 pär, with its 11 compounds, compar, impár, diápár.

2. Ser erat extrum, placidique tepentibus aures. *Virg.*
5. Ducit ad auriferas quod nec filio Caeliter eras. *Mart.*
6. Inde mare, inde ars, inde eter iger ute Virg.*
7. Fer erat, et puri lucida mica tales. *Ovid.*
10. Multa quidem dict, eter excedant aliter. *Hor.*
12. Ludicr õr, impl, inequate in aruidus longa. *Hor.*

15. Words ending in AS, lengthen the final syllable; as màs, vás, crás, fás, amás, farás, piétas, Thomás, Maías.

Hst autem terris, itaque hanc vitrientur oram— *Virg.*

1. Greek nouns in as are short, which make the genitive in adas or adis, as Arcas, Pallas, Lampas, Ílias; to which add the noun Annás, and Latin nouns in as, formed after the manner of Greek patronymics; as Appías.

2. Allo the final as of Greek accusatives plural of the third declension is short; as crateras, lampadas, Trolis, Cyclopás, heroas, heroïdas, Heétoras, &c.

2. Et pietis annus enovata pennis. *Petron.*
3. Appis expresx-eru pulsat aquis. *Ovid.*
4. Nubes his venae, que nonquum erufere pollet— *Ovid.*

16. Words ending in ES lengthen that syllable; as rés, spés, vulpes, quiés, heres, cfés, Anchises, toties, locuples.

Pulpes ad extam dicitur deoctam. *Phaedr.*

1. The nouns and vocatives plural of Greek nouns increasing (not in es) short in the singular, are short; as Amazonés, Arcades, Delphínés, Náladés, Gyphnés, Phrygés.

2. To which may be added Greek vocatives singular in es, coming from nominatives in es, not formed from en, of the Doric dialect, and having their genitive in es; as Demothenés, Socrates.

D d

3. Es,
QUANTITY.

3. * Er, in the present tense of *jum*, and its compounds, is short; as *ades, abes, prodés, potes*, &c.; and in the preposition *en*.

4. Latin nouns of the third declension, in *er*, increasing short in the genitive, are short in the final syllable; as *hebès, alès, pedès, limès, obsès*. But *er* is long in these following; Cerès, paries, aries, abies, pes, and its compounds, as *bipes, tripèse, alipes, founpèse*; to which some add *prepèse*, a derivative of *prepeto*.

2. *Quaquis er, anfifio hine jam obl桓fifico Graia*. Virg.
4. *Ovino*.
5. *Aviun eras rapris non hajfis ab hospite tuus*. Ovid.
8. *Defuer Aurore dexter ãtis immnent alter*.
9. *Sta fœnipes*; et frons fœnum vumpantia mundi.*

*Note.*—1. Though *er* in the present tense of *jum* and its compounds is short, it is not in any other tense, nor in the final syllable of *gifs*, (as has been afoferted;) as

*Poîfes in tuto vivere magis?* 

*Epès boni facta puellas maris.* Propret.

2. Whenever paries, aries, and abies are found long, there happen to be a cætura; and perhaps Ceres and pes are long by dialetto: Auctorum florissent bipes and triges; and Probus observes that alipes and fonipes are likewise short; though the contrary appears in Virgil, Lucan, and Horace, yet some of the above-mentioned words could not be introduced into bis verse without the influence of a heurz to lengthen their final syllable. Prapes, which comes not from pes, but from *eporess* is short in Virgil. (*En. 5. 554*) Tigres, ascribed to Ovid, is, by the bell critics, rejected.

17. IS final is short; as *bis, is, quis, cis, magis, turris, militis, creditis, Theis*.

Tom *bis ad occasum, bis fe convertit ad ornum.* Ovid.

1. Except *plural cafes in is; as nobis, vobis* ("quis for quibus"); musis; the plural accusatives *oamis*, *uris, &c.*

2. The nominative in *is long, when the 3 genitive ends in *itis, inis*, or *enîs long; as is, Samuis, Samulis, Saimis, Simeois.*

3. *I* is long in the adverbs *gratis and foris*; in the noun *glis*, and in *vis*, whether noun or verb.

4. All *2nd perons singular in *is* are long; when the 2nd persons plural have *etis* long; as *cis, fis, is, abis, audis, velis, nolis, pois*, &c. *Ris* of the perfect is commonly considered short, of the *1 future*, common; so are the penultimates of *ausis and faxis*; *ris and ritis* of *ero* and *potero* are more frequently short.

1. *Indoezquac et; dos adis vitel munus* Mart.
2. *Qua quic et qarmus Patroon Trogue ibam munis abis* Virg.
3. *Non omnis arbulis juvent, humifieque myricas* Virg.
7. *Luna cætura et fine pondero cæl* Ovid.
10. *Ouvar eripere normus & collas verbam* Hor.
11. *Qua qem gentes ibam, aut quis non aevaeur urbem* Virg.
12. *Da minis putiondum; deduxis in carmine visce* Virg.
13. *Fortunata puer, tu mi hori fter abit* Virg.
14. *OS final is long; as ros, vos, nos, mos, floe, trus, arbis, bonos, cepus, nepis.* Ovid.

*Et hominis subline dedix, coelique turri.* Ovid.

1. Except *Greek genitives in *er*; as Arcades, Te- 

2. Alto compus, impos, and *ôos-offis, with its compounds exos, has the final syllable short.*

3. *Greek nominatives and vocatives of the second declension have *er short; as Claros, Tenedos, Lefbos, Artops.* But those nouns of the Attic dialect, having their genitives in omega, are long, as *Androgeôs, AThôs*; also nouns of the same dialect, which have changed faur (*Xeit*) into *fer* (*Xeit*), as *Peneleôs, Menelaôs.*

4. *Greek neuters in *er are short; as *Argos, epox, 

5. US final is short; as tenus, littos, pentus, intus, Ambobus, Montibus, Ambamus.*

Inque: *ponentes servabat Tityuebas haedon.* Virg.

1. Except *monosyllables in *er; as grâus, plûas, rûas, thûas, jîus.*

2. *Alfo the *genitives of feminine nouns in *er; as Clîis, Sapphûs, Mantûs.*

3. *Genitives singular, and nominatives, accusatives, and vocatives plural of the fourth declension, (all being contracted,) have *er long; as fructûs, manûs.*

4. *Alfo nouns increasing long in the genitive; as palûsûdis, virtûsûdis, tellûsûdis, Opûsûntûs.*

5. *Ur* is long in the *3 compounds of *are; (forming the genitive in *odis or *podos,) as *Tripûs, Melampûs, Zedûps, Polypûs.*

6. *Alfo those nouns which have *er in their vocative; as Pantûs, O Panthu.*

7. *Finally, *Is* has the final syllable long.*

1. *Romûs tus opes, abstem munus urbem.* Hor.
4. *Ridet aper; neque adue; et iles in tridibus ulta et.* Ovid.
7. Et *cæs et *eris veneeram omnem *fius.*

18. *YS final is short; as Capûs, chelys, chamûs.*

At *Gyptûs, et quorun molis fuentia mentis.* Virg.

*Except nouns which form the nominative in *en also; gortûs, Phercûs. To these add contracted plurals; as Erynnûs, for Erynnyês, or Erinnyês.*

21. *Final *er shortens the preceding vowel; as capûs, amit.*

Venam hor sanctum alius inter; capûs *eautul urb.* Virg.

*Except when final *er is long by *crasis; as redit for redit or redvit.*

22. The last syllable of every verbe is considered common; that is, if the syllable be naturally long, it may be accounted short; or, if it suit the verbe, *vire *verûs.*

Genûs inanitus mihi *Tyrrheenis navigat epûs.* Virg.

Credît occulta quid *abev arîs.* Hor.

*Note.—1. In the first of these examples, *er* naturally short, forms the second syllable of a *qondens*; in the last, a *Sapphûs verbe, the word *er* which is naturally a *qondere, forms a *troechee.*

2. *The *er genitives which differ from *er in *er, by saying that the last syllable of a verbe is common, only mean, that the local quantity superficied the natural quantity of *er syllable.*

For the last principal head of profosdy; see *Vereification.*

QUAN-RTSOM, in Geography, a town of China, of the third rank, in Pe-teche-li; 32 miles S. of Chunte.
QUANTUM Meruit, called also an affumpfius, in Law, an action upon the cafe, grounded upon a necessity to pay a man for doing any thing so much as it deferves or merits.

This valuation of his trouble is submitted to the determination of a jury; who will affefs such a fum in damages as they think he really merited.

QUANTUM Valebat, or an implied affumption, is where goods and wares fold, are delivered by a trader at no certain price, or to be paid for them as much as they are worth in general; then quantum valebat, or an action on the cafe, lies, and the plaintiff is to aver them to be worth fo much; fo where the law obliges one to furnish another with goods or provisions, as an inn-keeper his guests, &c.

QUANTZ, John Joachim, in Biography, chamber musician to Frederic II. king of Prufia, to whom he had been flute-maifer before his accession to the crown. Quantz was born at Oberfcheiden, a village in the electorate of Hanover, in 1697. His father, who was a blacksmith, obliged him to work at the anvil before he was nine years old; which mufh have afforded him an early opportunity of making the famous Pythagorean experiment, mentioned by Jamflchus (de Vit. Pythag.), and by all the musical writers of antiquity. Indeed, the ear of our young Ardalus had been already formed, in his excursions with his brother, a village musician, who ufed to play about the country on holydays and feftivals, whom he accompanied upon these occasions, on the fafe-viol, when but eight years old, and without knowing a note of music; but this performance, bad as it was, pleased him fo much, that he determined to choose music for his profeflion; though his father, who died when he was only ten years of age, recommended to him, on his death-bed, to continue in the honourable profeflion of his ancerlors.

Quantz, after lofing his father, had no other friends to depend upon for counsel and protection, than two uncles, who lived at Merfburg in Saxony; and thence, from and for him, gave him the choice of their several profeflions, the one being a taylor, and the other a kunfpfeifer, or town-wait. Upon this occasion, the passion for music in the young Quantz overpowered all other conderations, and, preferring the fiddle-thick to the anvil or hearth, he bound himself apprentice to his uncle, the musician, for five years; but this uncle dying three months after, he was transferred to his fon-in-law, Fleifchhack, who was of the fame profeflion; and it was under him that he firft practifed the violin, an instrument to which his inclination at this time impelled him, preferably to any other.

Soon after this, however, he practifed the hautbois, and the trumpet, with which instrument, and the violin, he chiefs filled up the term of his apprenticefhip; but as a true town musician, in Germany, is expected to play upon all kinds of instruments, he had been obliged, occasionally, to apply himself, during this period, to the fackbut, cornet, fafe-viol, French horn, common flute, balfoon, viol da gamba, and the lord knows how many more. Thofe were in the way of business, but for pleafure, he now and then took leffons on the harpsichord, of the organifft Kiewefett, who was likewise his relation; by which he laid the firft foundation of his knowledge in harmony, and love for compofition.

Luckily for Quantz, his maifer, Fleifchhack, was not, like other country musicians, fond only of old, dry, stiff, and taffeful compositions, but had fufficient deferement to choofe his pieces out of the newest and best productions of the times, by Telemann, Melchoir, Hofmann, and Heinichen, which were published at Leipfic; from the perufal, and prattife of which, our young performer derived great advantage.

The duke of Merfburg’s hand not being very numerous, the town-waits, at this time, were often called in, to affift at the musical performances, both of court and chapel. Here Quantz frequently heard foreigners play and sing, in a manner far superior to any profeflors whom he had hitherto met with, which excited in him a strong defire to travel. Drefden and Berlin were at this time the most renowned cities in Germany, for the cultivation of music, and the number of able musicians. He eagerly wished to visit one of fuch cities, but was deftitute of the means. However, he now began to think of himself, and trufting to his feet and his fiddle, he boldly set oft for Drefden.

It was in the year 1714 that he arrived in that city. His firft entrance was not fpacious, being wholly unable to procure employment; on this account, he made an excursion to Radeburg, where a journeyman fiddler being wanting, he entered into the service of the town musician, Knoll; but alas! he was soon driven from this poll, by the fatal accident of the town being burnt down by lightning. Again reduced to the flate of a fugitive, and a wanderer, he levied contributions round the country by the power of his violin, which was now his principal instrument, till he reached Pirna.

Here, defirous fll to be ferois fervorum, he could procure no other means of exercising his profeflion, than by accepting the office of deputy to a fick journeyman musician of the town. It was during this time, that he firft faw Vivaldi’s concerto’s for the violin, which were fo congenial to his own feelings and ideas of perfection, that he made them his model as long as he continued to prattife that instrument.

Still regarding Drefden as his centre, he eagerly accepted an offer that was made to him, of being temporary affitant there, to one of the town-waits, who was then ill; an employment which he preferred, for the opportunities it afforded him of hearing good music and good musicians, to the more honourable poll of being the bell of bad musicians at Berenburg, where he might have been appointed firt violin, with a good falary.

His second arrival at Drefden was in the year 1716, where he soon discovered that it was not fufficient for a musician to be able to execute the mere notes which a composer had set on paper; and it was now that he firft began to find the feeble of the existence of talent and expreffion.

Augustus II. was at this time king of Poland, and elector of Saxony, and the orchestra of this prince at Drefden was in a flourishing condition; however, the style which had been introduced there, by the concert-maifer Volmir, was French; but Pfenfel, who succeeded him, introduced a mixed taffe, partly French, and partly Italian, which he afterwards brought to fuch perfection, that Quantz declares, he never heard a better band in all his future travels.

No orchestra in Europe could now boaft of fo many able profeflors, as that of the elector of Saxony, among whom, were Pfenfel and Veracini, on the violin; Pantalcene Hefenfreit, on the pantalone; Weifs, on the lute; Richter, on the hautbois; and Buffardin, on the German flute; not to mention several excellent performers on the violoncello, balfoon, French horn, and double-bafe.

Upon hearing these great performers, Quantz was filled with fuch wonder, and polledled of fuch a rage for improvement, that he laboured incessantly to render himself worthy of a place among fuch honourable associates.

For, however prejudiced he may have been in favour of his own reputable calling of kunfpfeifer, he began now just to think it poible for him to be prevailed upon, to relinquish that part of it, at leaft, which required him to play
country dances, though in itself so jovial, pleasant, and feftal an employment.

He continued, however, to be the kumpeifer's delegate in this city, till the death of Augustus II.'s mother, in 1717, at which time, the general mourning proffering the use of every species of convivial mufic, he again, in his usual manner, commenced traveller, and fiddled his way through Silefia, Moravia, and Austria, to Vienna; and in the month of October, of the fame year, returned through Prague to Drefden; which journey, he thinks, contributed more to his knowledge, in practical geography, than in any other art.

The jubilee of the reformation, brought about by Dr. Luther, happening to be celebrated soon after his return, he was called upon, among others, to perform a part upon the trumpet, at church, where the chapel-maifter Schmidt having heard him, offered to prevail on the king to have him regularly taught that instrument, in order to qualify him for the place of court trumpeter; but Quantz, however ardently he might have wished for an office at court, declined the acceptance of this, well knowing that the good taste to which he aspired, was not to be learned upon that instrument, at least as it was then played in Drefden.

In 1718, the Polish or royal chapel was inilituated; it was to consist of twelve performers, eleven were already chosen, and a hautbois player, only, was now wanting, to complete the number. After undergoing the severe trials, and giving the requisite proofs of his abilities, he had the happiness to be invited with that employment, by the director, baron Seyferitz, with a salary of 150 dollars, and a lodging.

This was an important period in his life, and in the exercise of his profession. The violin, which had hitherto been his principal instrument, was now laid aside for the hautbois, upon which, however, he was prevented from distinguishing himself, by the scarcity of his brethren. Mortified at this circumstance, he applied himself seriously to the German flute, upon which he had formerly made some progress without a matter; but his motive now for refuming it, was the certainty of his having no rival, in the king's band, as M. Fries, the first flute, had no great talent for music, and readily relinquished to him his place.

In order to work upon bare ground, Quantz took lessons at this time of the famous Buffardin, with whom, however, he only played quick movements, in which this celebrated flute-player chiefly excelled. The scarcity of pieces composed expressly for the German flute, was such, at this period, that the performers upon that instrument were obliged to adopt those of the hautbois, or violin, and by altering or transposing, accommodate them to their purpose, as well as they could.

The intimated Quantz to compose for himself; he had not as yet ever received any regular instructions in counterpoint, so that, after he had committed his thoughts to paper, he was obliged to have recourse to others to correct them. Schmidt, the chapel-maifter, had promised to teach him composition, but delayed keeping his word from time to time, and Quantz was afraid of applying to Heinichen, his colleague, for fear of offending Schmidt; as their matters were upon bad terms together. In the mean time, for want of other affinities, he diligently studied the scores of great masters, and without stealing from them, endeavoured to imitate their manner of putting parts together, in trios, and concertos.

About this time he had the good fortune to commence a friendship with Pfändel, now appointed concert-maifter, in the room of Volmirer. Quantz is very warm in his praises of Pfändel, whom he calls a profound theorist, a great performer, and a truly honest man. It was from this worthy concert-maifter that he learned to perform an adagio, and to compose in many parts. Pfändel had in his youth been taught to fing by the famous Pitiochi, and had received instructions, on the violin, from Torelli; however, having travelled through France and Italy, where he had acquired the peculiarities in the taste of both countries, he fo blended them together as to form a third genus, or mixed style of writing and playing, which was half French and half Italian.

Influenced by his example, Quantz declares, that he always preferred this compound style, to that of Italy, France, or the national style of his own country.

At the marriage of the Prince royal of Poland, in 1719, several Italian operas were performed at Drefden. Lotti, the famous Venetian maestro di capella, together with the most celebrated fingers of Italy, male and female, were called thither upon this occasion; there were the first Italian operas which Quantz had heard, and he confesses, that the performance of them gave him a very favourable idea of the genuine and sound Italian mufic, from which he thinks later times have too much deviated.

After describing the talents of the fingers who will have their place in our alphabet, he informs us that this famous opera at Drefden was broken up by a quarrel between Heinichen, the king of Poland's chapel-maifter, and Senefino, who this same year, 1719, went to England for the first time.

Nothing very interesting occurs in the life of Quantz from this period, till 1723, when he took a journey with Weifs, the famous lutinist, and Graun, the compiler, to Prague.

Quantz, not long after the coronation of Charles VI. at Prague, went to Italy in the suite of count Quevaceo, with the consent of his royal maifter, the king of Poland. He left Drefden in May 1724, and, when he arrived at Rome, he found that Vivoldi had fully introduced the Lombard style in that city, with which the citizens were so captivated, that they would hear no other.

During his residence at Rome, he took lessons in composition of the famous Gasparini, who was at that time twenty-two years of age; and after studying counterpoint with him, which he calls music for the eye, he went to work for the ear, and composed solos, duets, trios, and concertos; however, he confesses, that counterpoint had its use in writing pieces of many parts; though he was obliged to unlearn many things, in practice, which theory had taught him, in order to avoid that dry, and stiff style, which too close an adherence to rules is apt to produce; upon this occasion, he very judiciously observes, that invention is the first requisite in a composer, and that it behoves him to preserve a friendship between harmony and melody.

In 1725 he went to Naples, where he met with his countryman Haffe, who then studied under Alex. Scarlatti. Haffe had not, as yet, distinguished himself by any compositions for the stage; however, it was at this time, that a consider able Neapolitan banker employed him to get a serenade for two voices, which he did in the presence of Quantz; the fingers who performed it, were Farinelli and Pesè. Haffe gained so much reputation by this production, that it paved the way to his future success, and he was soon after appointed composer of the great opera at the theatre royal.

Quantz intreated Haffe to introduce him to his master, Scarlatti, to which he readily consented; but upon mentioning him to the old composer, he said, "my son, you know I hate wind instruments, they are never in time." However, Haffe did not cease importuning him, till he had obtained the permission he required.
In the visit which he made to Scarlatti, M. Quantz says, that he had an opportunity of hearing him play on the harpsichord, which he did in a very learned manner; but observes, that his abilities on that instrument were not equal to those of his fon.

Before his departure from Naples, M. Quantz frequently heard concerts at the Duke of Lichtenstein's, in which Haafle, Farinelli, Teiri, and Franciscoelli, were employed.

In 1726 he was at Venice, during the performance of two rival operas, "Siface," composed by Porpora, and "Siroe," by Vinci; the latter was most applauded. The Cav. Nicollini, a contralto, La Romanina, a deep sopranio, and the famous tenor, Paitsa, were the principal singers in these dramas.

San Martin, the celebrated performer on the hautbois, who afterwards established himself in London, was now at Venice, as was Vivalli.

At Turin he met with Somis, under whom, Le Cloire was at that time a scholar on the violin.

From Turin he went to Paris, which, with respect to music, was going from one extreme to another.

His character of French singing in the former part of the last century, is very just and characteristic.

"I was displeased with the French style now," says M. Quantz, "though I had heard it formerly with patience. The old, worn-out, first-hand thoughts, and passages ill-expressed, disgust me now, as much as a float dith warmed again. The resemblance between recitative and air, with the affected and unnatural bowing of the fingers, particularly the women, shocked my ears."

M. Quantz was the first who applied an additional key to the German flute, in order to correct its imperfections; and it was in the course of this year, 1726, that he made the discovery.

In 1727 he arrived in London, where found the opera in a very flourishing state, under the direction of Handel. The drama of "Admetus" was now in run, of which, he says, the music was grand and pompous. Seneforo performed the first male part, and Cuzzoni and Faustina were the principal women.

He then gives a character of the fingers, flutes of the opera, and of music in general in London, very correctly.

Upon his return to Dresden, he was established in the king's chapel, with an addition to his former salary of 250 dollars a-year. He now entirely quitted the hautbois, supposing it hurtful to the enjoyment of the flute, which, from this time, he made his sole study.

In 1728 he went to Berlin, with baron Seyfertiz, in the suite of the king of Poland; where he was obliged, at the command of the queen of Prussia, but with the permission of his royal master, to remain for some months. Pifendel, Weis, and Buffardin, were, by the same order, called thither. After he had had the honour of playing before the queen two or three times, he was offered a place and pension of 800 dollars a-year. He was very willing to accept of them, but the king his master would not grant his consent: however, this prince gave him a general permission to go to Berlin as often as he desired.

This year, 1728, the prince royal of Prussia determined to learn the German flute, and M. Quantz had the honour to teach him. On this account, he was obliged to go twice a year to Berlin, Rappin, or Reinsberg, the several residencies of his royal scholar.

After the death of the king of Poland, in 1733, his son, Augustus III. not choosing to dismiss M. Quantz, raised his appointment to 800 dollars, and confirmed the permission which had been granted by his royal father, for his going occasionally to Berlin.

In 1734 he published his first folio; but he does not acknowledge the Ionatas, which were printed under his name, in Holland, about that time.

In 1739, M. Quantz finding a great scarcity of German flutes, undertook to bore them himself for the use of his pupils; an enterprise which, afterwards, he found to be very lucrative.

In 1741 he was again invited to Berlin, in order to enter into the service of his royal scholar; then king of Prussia, with offers of an annual pension of 2000 dollars for life; a separate payment for compositions; 100 ducats for every flute he should deliver; and an exemption from playing in the orchestra, or any where else, but in the king's chamber, as well as from dependance on any other commands than those of his majesty; which terms, as the king of Poland was too gracious longer to refuse his dismissal, M. Quantz was unable to refuse.

In 1752 he published his "Art of Playing the German Flute," and it was this year that he invented the new joint for the upper-piece of the flute, by which means, without drawing out the middle piece, and without hurting the tone, the instrument may be raised or lowered half a note.

And now, having traced our indolent musician through the troublesome mazes by which he arrived at the temple of fortune, we have hopes that we should have left him to the enjoyment of that reputable cafe, that sym. cum dignitate, to which every artist in years aspires; but alas! this eminent musician and worthy man died at Potsdam in less than a year after we had seen, heard, and converted him in that sumptuous residence of his royal disciple and patron! A complete list of his works is given in Gerber.

QUANUSE, in Geography, a town of America, in the Tennessee government. N. lat. 35° 12'. W. long. 84° 28'.

QUAPA, a town of Louisiane, at the confluence of the Akanfia with the Mississippi. N. lat. 33° 48'. W. long. 91° 23'.

QUAPACTOTOTIL, in Ornithology, a name under which Nieremberg has described a bird, which, he says, imitates the human laugh. He says its body is eight inches long, and the tail as many; the beak of a blueish-black, and bent and crooked; the breast grey, and the belly black; the tail of a brownish-black; and the wings, neck, and head, of a yellowish-brown.

This is the Cuculus ridibundus of Gmelin, the Cuculus Mexicanus of Brisson, and the Laughing cuckow of Latham. It is found in New Spain.

QUAPIZOTTI, in Zoology, the name given by Hervas to the Tajo of Malagrave, the Pecari of Buffon, and the Mexican hog of Pennant. See Sus Tajafr.

QUAPOA, in Botany, Aubl. Guin. v. 2. 897. t. 343, 344, a barbarous Caribean name. See XANTHE.

QUAR, in Agriculture, a term occasionally employed, in a provincial manner, to signify a small fort of quarry of any kind, but more especially of the lime-stone, free-stone, flag-stone, or slate-stone nature. It is much used in some of the more northern districts of the country. See Quarry.

QUARANTAIN, in old Law Books, written Quarentani, and Quarentinus, denotes the space of forty days.

"Quarantina in Lomoun, ponitur pro respectu habend. 40 dies poul munimentonem per breve regis, ut confonunt, etc. si viderint expedire." MS. de Temp. Ed. III.
The term is borrowed from the French quarantaine; and is sometimes used for the time of Lent.

Quarantine of the King, in France, denotes a truce of forty days appointed by St. Louis, during which time it was expressly forbidden to take any revenge of the relations or friends of people who had fought, wounded, or affronted each other in words.

Quarantine, or Quarantines, is more particularly used for the term of forty days, which vessels, coming from places suspected of contagion, are obliged to wait in certain places appointed to air themselves before they come into port.

By the Act 26 Geo. II. cap. 6, explained and amended by 29 Geo. II. cap. 8, the method of performing quarantine, or forty days probation, by ships coming from foreign countries, is put in such a more regular and effectual order than formerly; and matters of ships coming from infected places, and disobeying the directions there given, or having the plague on board, and concealing it, are guilty of felony without the benefit of clergy. The same penalty also attends persons escaping from the lazaretto, and officers and watchmen neglecting their duty, and persons conveying goods or letters from ships performing quarantine. See Plague.

In cases of insurrection, before the risk on a ship can be said to be completely ended, the mast not only have been 24 hours moored at anchor in her port of destination, but the mast have been during that time in good safety, in the fullest sense of those words. If, therefore, the ship be obliged to perform quarantine, this does not end the voyage. The voyage only ends when the ship is arrived at her port of destination, and is there moored 24 hours in good safety. Accordingly, if the ship, before the 24 hours are expired, be ordered to the proper place for performing quarantine, the risk continues, though she do not leave her moorings till long after the 24 hours are expired. See Risk.

Quarantine also denotes certain duties imposed upon ships, for the purposes of quarantine.

Quarantine, Quarantine, or Quarantine, Quarantina, in Law, denotes a benefit allowed by the laws of England to the widow of a man dying feized of land; by which the law challenges to continue in his capital fief, or chief manor-house (so it be not a castle), for the space of 40 days after his decease; during which time her dower shall be allowed. The particular lands to be held in dower must be alligned by the heir of the husband, or his guardian. Co. Litt. 34. 35.

If the heir, or any other person, attempt to eject her, she may have the writ of quarantina habendi; which lies for a widow to enjoy her quarantine.

Quarantine is also used for a mere piece or extent of land, containing 40 perches.

Quarantaria, in Geography, a high mountain between Jerusalem and Jericho; which, as tradition says, is the mountain to which our blessed Saviour was taken by the devil, when he tempted him with the visionary scene of all the kingdoms and glories of the world. This is, as St. Matthew styles it, an exceeding high mountain, and not only difficult, but dangerous, of ascent. It has a small chapel at the top, and another about half-way of its ascent, founded upon a prominent part of the rock. Near this latter are several caves and holes in the side of the mountain, made use of by hermits, and by some in later times, for places in which they kept their Lent; in imitation of that of our blessed Saviour. In most of these grots, Maundrell found certain Arabs quartered with fire-arms, who obstructed his ascent, demanding 200 dollars for leave to go up the mountain. He and his companions, says the traveller, departed without further trouble, not a little glad to have so good an excuse for not climbing so dangerous a precipice. Maundrell's Journey, &c. p. 80.

Quarantine, in the Venetian Polity, a court of judicature composed of forty judges.

The Venetians have an old civil quarantia, a new civil quarantia, and a criminal quarantia.

The criminal quarantia takes cognizance of all crimes except those against the state, which belongs to the council of ten. The new civil quarantia judges of appeals made from sentences made by judges out of the city; The old civil quarantia takes cognizance of appeals from sentences of hubsters judges in that city.

Quarantine, in Botany. See Myrodia.

Quaere clausum frigeti, in Law. See Clausum frigeti.

Quaere eject infert terminum, a writ which lies, by the ancient law, where the wrongdoer or ejector is not himself in possession of the lands, but another who claims under him. As where a man leaves lands to another for years, and, after, the lessor or reveriesenter entereth, and maketh a feofment in fee, or for life, of the same lands to a stranger; now the leeshee cannot bring a writ of ejectio fines, or ejectment, against the feoffee; because he did not eject him, but the reveriesenter; neither can he have any such action to recover his term against the reveriesenter, who did ouf him; because he is not now in possession. And upon that account this writ was devised, upon the equity of the statute Welfm. 2. c. 24; and so in a case where no adequate remedy was already provided. And the action is brought against the feoffee for forcing, or keeping out, the original leeshee during the continuance of his term; and herein, as in the ejectment, the plaintiff shall recover so much of the term as remains; and also shall have actual damages for that portion of it, whereas he has been unjustly deprived. But since the introduction of fictitious ousters, whereby the title may be tried against any tenant in possesion, (by what means ever he acquired it,) and the subsisting recovery of damages by action of trespass for mense profits, this action is fallen into disuse. See Ejectione Firma.

Quaere impedit, a writ which lies for him who has purchased an advowson, against him that disturbs him in the right of it, by presenting a clerke to it when the church is void.

It differs from the affize of darren presentment, ultime presentationis, which lies where a man, or his ancestors, formerly presentated; this other lying for him who is the purchaser himself. Where a man may have the affize, he may have this writ, but not contrariwise.

In contested presentations, upon the first delay or refusal of the bishop to admit his clerk, the patron usually brings his writ of quaere impedit against the bishop, for the temporal injury done to his property, in disturbing him in his presentation. And if the delay arises from the bishop alone, as upon pretence of incapacity, or the like, then he only is named in the writ; but if there be another pretention set up, then the pretended patron and his clerk are also joined in the action; or it may be brought against the patron and clerk, leaving out the bishop; or against the patron only. But it is most advisable to bring it against all three: for if the bishop be left out, and the suit be not determined till the six months are past, the bishop is entitled to present by lapce; for he is not party to the suit: but, if he be named, no lapce can possibly accrue till the right is determined. If the patron be left out, and the writ be brought only against the bishop and the clerk, the suit is of no effect, and the writ shall abate; for the right of the patron is the principal question in the cause. If the clerk be left out, and has re-
received institution before the action brought, (as is sometimes the case,) the patron by this suit may recover his right of patronage, but not the present turn; for he cannot have judgment to remove the clerk, unless he be made a defendant, and party to the suit, to hear what he can allege against it. For which reason it is the fader way to inflict all three in the writ.

The writ of *quaere impedit* commands the disturbers, the bishop, the pseudo-patron, and his clerk, to permit the plaintiff to present a proper person (without specifying the particular clerk) to such a vacant church, which pertains to his patronage; and which the defendants, as he alleges, do obstrue; and unless they so do, that they appear in court to shew the reason why they hinder him.

Immediately on the suiting out of the *quaere impedit*, if the plaintiff suspeets that the bishop will admit the defendant's or any other clerk, pending the suit, he may have a prohibitory writ, called a *ne admitterat*; which recites the contention begun in the king's courts, and forbids the bishop to admit any clerk whatsoever till such contention be determined. And if the bishop doth, after the receipt of this writ, admit any person, even though the patron's right may have been found in a *jure patronatus*, then the plaintiff, after he has obtained judgment in the *quaere impedit*, may remove the incumbent, if the clerk be a stranger, by writ of *feire facias*; and shall have a special action against the bishop, called a *quaere incumbravit*; to recover the presentation, and also satisfaction in damages for the injury done him by incurring the church with a clerk, pending the suit, and after the *ne admitterat* received. But if the bishop has incurred the church by ininitating the clerk, before the *ne admitterat* issue, no *quaere incumbravit* lies; for the bishop hath no legal notice, till the writ of *ne admitterat* is served upon him. The patron is, therefore, left to his *quaere impedit* merely; which now lies (since the statute of *Welfm. 2.* as well upon a recent usurpation within six months past, as upon a disturbance without any usurpation had.

In the proceedings upon a *quaere impedit*, the plaintiff must set out his title at length, and prove at least one presentation in himself, his ancestors, or those under whom he claims; for he must recover by the strength of his own right, and not by the weaknesses of the defendant's; and he must also shew a disturbance before the action brought. Upon this the bishop and the clerk usually disclaim all title: save only, the one as ordinary, to admit and inmitate; and the other as patron of the patron, who is left to defend his own right. And, upon failure of the plaintiff in making out his own title, the defendant is put upon the proof of his, in order to obtain judgment for himself, if needful. But if the right be found for the plaintiff, on the trial, three farther points are also to be inquired: 1. If the church be full; and, if full, then of whole presentation: for if it be of the defendant's presentation, then the clerk is removable by writ brought in due time. 2. Of what value the living is; and this in order to affe9s the damages which are directed to be given by the statute of *Welfm. 2.* 3. In case of plenary upon an usurpation, whether six calendar months have palled between the avoidance and the time of bringing the action: for then it would not be within the statute, which permits an usurpation to be directed by a *quaere impedit*, brought above six months after the vacancy happens; as it was universally by the common law, however early the action was commenced.

If it be found that the plaintiff hath the right, and hath commenced his action in due time, then he shall have judgment to recover the presentation; and, if the church be full by ininitation of any clerk, to remove him: unless it were filled *pendente lite* by lapse to the ordinary, he not being party to the suit; in which case the plaintiff loses his presentment *pro hac vice*, but shall recover two years' full value of the church from the defendant, the pretended patron, as satisfaction for the term lost by his disturbance: or, in case of infolvency, the defendant shall be imprisoned for two years. But if the church remaind still void at the end of the suit, then whichever party the presentation is found to belong to, whether plaintiff or defendant, shall have a writ directed to the bishop *ad admittanceam clericum*, reciting the judgment of the court, and ordering him to admit and institute the clerk of the prevailing party; and, if upon this order he doth not admit him, the patron may sue the bishop in a writ of *quaere non admitterat*, and recover ample satisfaction in damages.

Besides these possesory actions, there may be also had a writ of right of *advowson*, which resembles other writs of right: the only distinguishing advantage now attending it, being, that it is more conclusive than a *quaere impedit*; since to an action of *quaere impedit* a recovery had in a writ of right may be pleaded in bar.

There is no limitation with regard to the time within which any actions touching advowsons are to be brought; at least none later than the times of Richard I. and Henry III.: for by statute 1 Mar. l. 2. c. 5. the statute of limitations, 32 Hen. VIII. c. 2. is declared not to extend to any writ of right of advowson, *quaere impedit*, or affile of *darrain presentment*, or *just patronatus*.

In a writ of *quaere impedit*, which is almost the only real action that remains in common use, and also in the affile of *darrain presentment*, and writ of right, the patron only, and not the clerk, is allowed to sue the disturber. But, by virtue of several acts of parliament, there is one species of presentations, in which a remedy, to be fixed in the temporal courts, is put into the hands of the clerks preferred, as well as of the owners of the advowson. We mean the presentation to such benefices, as belong to Roman Catholic patrons; which, according to their several counties, are vested in and secured to the two universities of this kingdom. And particularly by the statute of 12 Ann. l. 2. c. 14. § 4. a new method of proceeding is provided; viz. that, besides the writs of *quaere impedit*, which the universities as patrons are entitled to bring, they, or their clerks, may be at liberty to file a bill in equity against any person presenting to such livings, and disturbing their right of patronage, or his *eijusque terrae*, or any other person whom they have cause to impedit; in order to compel a discovery of any secret truits, for the benefit of Papists, in eva9ion of those laws whereby this right of advowson is vested in those learned bodies: and also (by the statute 11 Geo. II. c. 17.) to compel a discovery whether any grant or conveyance, said to be made of such advowson, were made bona fide to a Protestant purchaser, for the benefit of Protestants, and for a full consideration; without which requisites, every such grant and conveyance of any advowson or avoidance is absolutely null and void. Blackl. Com. b. iv. Quaere

*Quaere incumbravit*, a writ which lies against the bishop, who, within six months after the vacancy of a benefice, comers it on the clerk of any one, while two persons are contending at law for the right of presenting. This writ lies always depending the plea. See the preceding article, *Presentation, Assise of darrain presentment, &c.*
QUA

Quare non admissit, a writ which lies against the bishop, for refusing to admit his clerk, who has recovered in a plea of advowson, on pretence of lapse, &c. See Quare imped.

Quare non permitis, a writ that lies for one who has a right to present for a turn against the proprietary.

Quare obfrustri, a writ that lies for him, who, having right to pass through his neighbour's grounds, cannot enjoy the same, because the owner has fenced it up.

Quarentine. See Quarantine.

Quarera, or Quarantia. See Quarry.

Quaritz, in Geography, a town of Sieïna, in the principality of Globug, 8 miles W. of Gross-Glogau.

Quarken, or Querken, a cluster of small islands, in the gulfs of Bothnia, near the eait coast. N. lat. 65° 16'. E. long. 21°.

Quarles, Francis, in Biography, an English poet, born in 1592, near Rumford, in Essex, was son of James Quarles, esq. who held an office at the navy board in the reign of queen Elizabeth. The subject of this article was educated at Chrift's-college in Cambridge, and was afterwards entered a student in Lincoln's Inn. He obtained the place of cup-bearer to the queen of Bohemia, daughter to James I.; and upon his return, he was appointed secretary to archbishop Uher in Ireland, from which country he made his escape, on the breaking out of the rebellion in 1641, after the los of his property. He had before distinguished himself by some works, chiefly on religious subjects, in consideration of which he had a pension from Charles I. About this time he had the post of chronolger to the city of London. On the commencement of the civil wars, he gave great offense to the parliament by a work, entitled "The Loyal Convert," and when he actually joined the king at Oxford, he was plundered of his estates, books, and manuscripts. These loss he did not long survive. He died at the age of 57, in 1644. Of his numerous writings, as well in prose as in verse, the most celebrated, and indeed by which he is almost entirely known, is his "Emblems," a set of defigns exhibited in prints, and elucidated by some lines attached to each. A considerable part of the work is borrowed from the "Emblems" of Hermannus Hugo, but his verses are his own. For a considerable time they excited a large portion of public admiration in the religious world. They then fell into contempt; but we believe a new edition has of late years been given to the world. Quarles is thus characterized by an able critic: "He is by no means without his beauties; and his verses, which are generally smooth, afford occasional bursts of fancy, and strokes of pathos, which are not genius, though overrun with fäls talk. Mr. Jackon of Exeter, in his "Letters on various Subjects," endeavoured to recall the public attention to this neglected poet, and pointed out with much feeling some of his brilliant passages; but though curiosity may be amused by hunting for his scattered beauties, he can never regain a place among the English classical poets."

Quarlesville, in Geography, a post-town of America, in Brunswick county, Virginia; 204 miles from Washington.

Quarnamela, a town of Sweden, in the province of Småland; 23 miles S. of Wexio.

Quarnero, or Conxero, Gulf of, a part of the Adriatic, between Itira and Morachia, anciently called "Sinus Fanaticus." It is subject to sudden storms and hurricanes, which render its navigation dangerous.

Quarrel, Fr. In old French munie, B quarre was the term for B. See Quadro.

Quarré les Tombes, in Geography, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Avallon; 6 miles S. of Avallon. The place contains 2007, and the canton 7287 inhabitants, on a territory of 1924 square kilometers, and 9 communes.

Quarrée, in the old French time-table, implied a breve, or square note, equal to two semi-brevi. See Time-table.

Quarrel, Querela, in Law. See Querela.

Quarrel seems properly to relate to personal actions, or to mole to mixed ones, wherein the plaintiff is called querus; and in all declarations of trefpat, it is said, queres.

Yet if a man release all quarrels or quarels, (a man's own deed being taken mole strongly against himself,) quarrel includes all actions; and accordingly all actions, both real and personal, are hereby released.

Quarrels or affrays in a church or church-yard are esteemed very heinous offences, as being indignities to him to whole service those places are consecrated; therefore mere quarrelsome words, which are neither an affray nor an offence in any other place, are penal here. See Affray.

Quarrel between the French and Italian singers at Rome, in the time of Charlemagne; for which we refer to our article Charlemagne. See also Rossina's Dict.

Quarrel, in Armory, a bolt, or square-headed arrow, to shoot out of an arsbiil, or cross-bow.

Quarrel of Glass. See Querry.

The word is formed, by diminution, from the Latin quadratum, or the French quarre, square; or, perhaps, immediately from the Italian quadrato, little square.

Quarry, in Agriculture, the common name of an opening, pit, drift, or shaft, which is dug into the earth or ground, and from which are to be raised ores of various kinds, different sorts of stones, flaves, and other materials of similar natures. It is remarked by the writer of the work on "Landed Property," that the more useful and advantageous materials and substances that have at different times been dug and raised out of quarries in this country, are chiefly those of the iron ore kind, lime-flone, and other calcareous matters, materials for building, such as flates, flags, liones, and substances of other sorts, matters for the constructing and repairing of roads, as sand, gravel, and others of the same nature, earthy substances for the purposes of different manufactures, such as clays, &c. moulds and vegetable earthy matters, and coals, with other articles for use as fuel. There are, however, occasionally raised from openings of this nature, a few other kinds of substances, such as will be noticed below.

It has been further supposed by the above writer, that the substances which he has here mentioned, may with truth be said to be of more real use and value to mankind than all the mines of precious metals in the world; that the eyes of the managers of landed estates should constantly be turned towards and fixed upon the discovery of the hidden valuable treasures and productions of this nature, wherever there is a probability or likelihood of their being to be met with. It is also supposed, that it would be highly beneficial and advantageous if mineralogists, and those who are acquainted with such substances, were to turn their attention towards the appearances or accompaniments which point out such useful concealed matters; as it might greatly facilitate the search for them, and frequently lead fortuitously to their discovery. The methods which are practiced in searching for and ascertaining the presence of different sorts of materials
QUARRY.

Iron-stone is likewise met with in Sussex in large quantities, imbedded with lime-stone and sand-stone, that which lies near to the surface being the best, the other having a coarser and more dull appearance, working heavier in the furnace. The very belt is frequently intermixed with thin stripes of soft marly matter. Iron-stone, to a great extent, exists on the elates of lord Dudley, and many others in Staffordshire, and contributes much to the employment and prosperity of the inhabitants. But, in the northern part of Lancashire, in the district of Low Furness, stone and one of this fort are perhaps found in the largest quantity, of the belt kind, and in the most general manner, of any where in the kingdom. There are numbers of shafts, quarries, and pits for working them from, on Lindal Moor, Whittittig Moor, and Crofs Gates, in the vicinity of Dalton, as well as in some other places. In the former, the working is usually effected at the depth of from twenty to forty-five feet, but it has been done at lees as well as greater depths. The whole of their cavities are chambered with wood, and coll from 2 guineas to twenty-five shillings in fencing each fathom, without the wood. The ore runs in veins or seams between the rocks on the north and south, being in breadth from about forty to sixty yards. And it constantly dips towards the south-east at the rate of about a foot in five or six. The belt ore is that which has the most greasy appearance, and it is raised with less difficulty, working less hard, requiring less flux, and forming a more soft iron. It is raised from the shafts or pits by machinery of the gin or windlass kind, the men employing picks, pincers, and hammers in digging it up. It was formerly got, in some places, by driving levels into the sides of the hills, and conveying it out on railways, in small waggons; but now the other way is mostly employed. Four men get about fourteen tons in the day, in some situations; but in others, double the number are required for getting the same quantity. It is wheeled to distant heaps, from which much of it is sent in small carts to the port of Old Barrow, from whence it is shipped to different parts of England, Wales, and Scotland, at the expense of from fourteen to thirty shillings in freight; and the rest converted into pig-iron by the furnaces in the neighbourhood. Iron-stones and ores are also met with in some other counties more to the north of the kingdom, where there are pits and quarries for raising them from.

Lime-stone is a very general sort of stone raised from quarries and pits in many different parts of this country, as in Devonshire, Sussex, Kent, &c. towards the south, where it lies in vall beds, from which it is dug for use; in the more midland counties, as in Gloucestershire, Shropshire, Derbyshire, Staffordshire, and others, where it exists and is employed to a still greater extent; but by far the most extensively in these farther to the north, as Lancashire, Wellmoreland, Yorkshire, Cumberland, and some districts of Scotland. In many parts of the county of Lancaster it is dug and raised from quarries, where it lies in a stratified manner at no great depth from the surface, being got up without much difficulty or trouble; while in other places it is forced from the solid rock, with great labour and expense. This is likewise the case in many other districts. Wherever it is met with, it is almost constantly a quarry material of great value, and which affords much employment to labourers.

In the county of Kent, the banks of some of the large rivers are scooped out into stone quarries in a remarkable manner, some of them worn out and disused, others in the state of being wrought. It has been observed, that this is the nearest stone country into which water-carriage can penetrate from the metropolis; and that the original London
was built, as well as the modern one chiefly paved, by materials from this district, such as the rag-flone, and the large pebbles gathered on the sea-flones, before the Scotch granite came into use. In the neighbourhood of Maidstone there are the appearances of many abandoned and neglected quarries of this nature; but the most considerable ones, which were lately wrought in that vicinity, are those of Farleigh and Fanti. In each of these, blocks of flones, of different kinds, and of every form and size, are met with, being separated by seams, and large irregular masses of earth of various qualities; among the rest, brick-earth of the belt quality. In some places, the flones are buried several feet under these earthy materials; in others, the rock rises to the surface. After this, the quarrymen worm their way; following it, with irregular windings, leaving behind them retreats in greater quantity than the useful materials which they raise.

The flony subflances which are principally met with in them, are of two very different kinds: the one hard, and of a strong contexture, provincially denominated rag, or Kentish rag; the other of a soft crumby nature, provincially termed haffack. The quarrymen are in the practice of dividing the first into two kinds; what they call the common rag, and the cork-flone, the latter being their principal object in these immense works. It has in its general appearance much resemblance to the strong grey lime-flones which are found in different parts of this country; but when minutely examined by means of a glafs, its fracture and contexture have the characters of the Devonshire marbles; except that the grain of this fort of flone is somewhate coarser. In colour, too, it differs from these flones, having a greater resemblance to the Yorkshire lime-flones. It is used for different purposes; much of it is sent to the neighbourhood of London, where it is burnt into lime, for the use of the sugar-bakers; who, for some reason or other, chiefly employ lime, burnt from this material, or flone, instead of that of chalk. It is likewise made use of as a building material; and, particularly in peddcrails, for the polls of cattle-feeding and other farm-offices. It is hewn with flone-masons’ axes, working with tolerable freedom.

It is very durable, as some part of the basement of Wealmington Abbey appears to have been built with the flone from these quarries. In this case, it seems to have been dressed smooth; and the surface still remains with little alteration; having withstood the attacks of time with great firmness; it being even now difficult to detect a loosened plintcr in the work.

The common rag-flone comprehends all the different kinds which are met with in these quarries, except that of the above, and that which is of the hafsocky nature; though the true unmixed rag is a difficult fort, having characters different from any of the others. In the colour, it inclines more to the red or liver colour, than that of the cork-flone, but otherwise resembles it considerably. Viewed with a glafs, its grain is finer, and the fracture flint-like.

Its uses are, however, but few. Some of the best and most regularly-faced flones are sometimes laid aside for paving materials: but the large pieces are mostly reftored, in order to be lent by water to the district of Romney Marsh, for the purpose of forming the hard materials of the embankments and jetties, which are there made against the sea. The smaller forts are, in general, converted to use as a road material.

The hafsocky flone appears to the naked eye to be of a soft, white, fangi quality; and its fracture is the same but under the glafs, its grain is fine, its contexture uniform, and so thickly interfileed with small fcll-like granules, of a dark or black colour, as to give it a grey appearance. Sometimes bearing evident imperfections of shells. Its texture is loose and brittle; crumbling easily between the fingers into a coarse faud-like powder. It will not burn into good lime, although it is almost wholly calcareous.

Its principal use is that of forming a loose friable fort of rubbly sub-foul, in some places, which is admirably suited to the growth of sainfoin, and some other crops of the plant as well as the fruit-tree kinds.

The quarries in several other counties contain flony materials of these different kinds, which are wrought and applied to a variety of different uses in these and other ways.

Quarries of marble are wrought in several districts in different parts of the country, and afford great advantages in various ways. In Suffolk they have a marble, which, when cut into slabs, is used for ornamenting chimney-pieces, and many other purposes. It is equal in quality and beauty to moth forts when highly polished. For square building and paving it is also a material fearcely to be exceeded. By burning, it likewise affords a very valuable manure, equal, and by some thought superior, to chalk, being cheaper to those who are near the places from which it is dug. It is found the most perfect about Kirdford, at the depth of from ten to twenty feet underground, in flaks nine or ten inches in thickncrs, and called the Petworth marble. It was much employed in building the cathedral at Canterbury, the pillars, monuments, vartnts, pavement, &c. being formed of it. And the archbishop’s chair is one entire piece of it. Marble is gotten in some of the counties in the middle of the island, as Derbyshire, Nottingahnire, &c. At Beacon-hill, near Newark, a romantic flone for hearths is got, which approaches to marble, and is capable of burning into lime. And in the country of Derby much good marble is raised in different places. In Lancashire there are quarries of fine black marble, and of flones, which approach to, and take on the polish of marbles. In many of the western and northern parts of Yorkshire, marble of various kinds is found, some much resembling, and others superior, in clofenefs of texture and dimenfions of colours, to that which is wrought in Derbyshire. Alto a flone, which greatly resembles the marble of that county, and which is capable of receiving much such a polish, and is nearly of the same colour, mixture, and appearance. On the side of the river Kent, near Kendall, a vein of beautiful marble has been lately discovered in the property of D. Wilfon, eq. of Dallam-Tower; and a main quarry opened upon it. Marble has also been met with on the oppofite bank.

In the country of Inverness, likewise, marble of the greatest variety of colours, and of the most beautiful thades, has been met with in Benvois, on the property of Mr. Camerton; and inexhaustible quarries of it lie untouched in the islands which belong to it.

Besides, this fort of material exists in immense quantities, in quarries, in many other parts of the kingdom.

Chalk is a material which is raised from quarries and pits, mostly in the southern parts of the country, as in Suffolk, Surrey, Kent, Essex, Berkshire, Hertfordshire, &c. It exists in vast ranges and tracts in mulf of thefe districts, whence it is dug up from quarries, at different depths, according to circumstances, exposed in sheds to dry, when wet, and then converted into lime for various uses, by means of fire, or employed in its broken and powdery flate, without undergoing the above proccfses, by merely digging it out of such places. In some parts, as in Kent, and the neighbouring districts, it is often dug and raised from con- siderable depths, from beds of very great thickncrs. And near Reading, in Berkshire, there is a flratum of this flone,
flance, which is thirty feet in thickness. It is there used and dug out for manure, and occasionally as a building material, for the latter of which purposes it is very durable. The remains of the abbey of Hurley, and of the ancient chapel, now the parish church, built wholly of chalk, in the reign of William the Conqueror, are, it is remarked by the writer of the corrected Agricultural Survey of the district, still as fresh and found as if they had been the works of the last century. Chalk, when once induced by the air, has a remarkable property in retarding the action of the weather.

Granite is a ffonny substance, which is found to exist in some of the southern parts of the country, as well as in those of the north, but it abounds more much in the latter.

In the western parts of Cornwall it is in great plenty in the districts of Penwith and Kierir, presenting itself in large flabs on all the rocky hills or tors, as well as in the wattle moors and valleys; and appearing in detached spots, even in the shelly flat tracts. It is of different colours and textures, being adapted to a great variety of uses and purposes, as those of building, and being wrought into column masses, eight or ten feet in length, for supporters to sheds, out-houses, &c.; and as gate-polls, and bridges over brooks, rivulets, &c.; as well as in the forming of rollers, malting, faling, and pig troughs. It is also an article of commerce to different parts. It is supposed to be exactly of the same nature with the original granite; and there are five to six of it, which are distinguished by their colours, the white, the dunce, or dove-coloured, the yellow, the red, and the black, most of which are charged with a brown and bright silverly matter.

The county of Inverness has a great deal of this sort of stone, and there are numerous quarries in it for raising and working of it. The common granite abounds in all the different districts of it. In many places the whole rocks are composed of this kind, which is uncommonly useful for all ordinary purposes. By natural fissures, which run in straight lines, and generally at right angles, it is formed into all sized portions and shapes, having uniformly a plain surface. And, by means of cutters or transverse lines, these stones are easily quarried, and found in the greatest plenty every where. They are remarkably beautiful, being almost as smooth and regular as hewn stone, and of course well suited for various sorts of building work. The best buildings of the county-town are of a dark kind of granite, which is very hard and durable, but which has few or no fissures. It is generally found in large blocks, and in many of these parts, there is no other material for building or adding ornament with. The manner of giving it the polish it admits of at the quarries, is by means of small picks, or pick axes, which are, in fact, hammers with sharp points at each end, in the manner of those employed by millers in preparing their grinding stones. It is a very heavy, compact stone. There is a mixed sort, denominated peaty granite, which consists of white, black, and grey spots, that sparkle beautifully in the sun, and is very ornamental, as well as much used for different purposes, as floors, doors, and windows. Though this is very solid, and almost without natural fissures, it splits very straight, by means of iron wedges, set in a line, and struck alternately, with a hammer of great power.

A great deal of this kind of stone is imported into the metropolis and other large towns, for paving the streets, &c. It is on the whole a very advantageous sort of quarry material in various parts of the kingdom.

Quarries of free-stone are wrought in a great number of different places. In the more southern parts is found the Portland stone, which is so famous and useful in building. A fort of this kind of stone, which much approaches it in quality, is also met with in Cornwall. Some likewise exists in Devonshire and Gloucestershire. The Cotswold quarries in the latter, afford free-stone of an excellent quality, particularly those at Painwick, Lodbury, Lockingham-hill, &c. It abounds more, however, in Cheshire, Lincolnshire, Wiltshire, Cumberland, and some of the still more northern districts. Several excellent quarries of free-stone are carried on in the firth of ffeve, as those at Runcorn, Manley, &c. where much valuable stone of this nature is raised. The second county also affords equally valuable quarries in many different places, from which vast quantities of the stone are raised, and employed, or sent away to a distance. Thofe about Ormskirk, Up-Holland, and Wiggen, as well as thofe on the eastern fide, are in general of a very good quality. And in the vicinity of Lancaster there are some excellent ones; that on the moor or common, close to the town, is very extensive, and affords a free-stone that admits of a fine polish. In this district, this fort of stone is met with of a whitish-brown, yellowish, and reddish, but the fife is by much the moft esteemed. In the eastern parts of Wiltshire, as about Hutton Roofe, and fome other places, a good fort of free-stone is dug up from pits and quarries formed for railing it. This fort of stone exists and is quarried almost all over the counties of Cumberland and Northumberland; and prevails occasionally in others, where it is wrought to advantage. A grit-stone, somewhat of this nature, is met with in fome districts, as in Shropshire, &c. which is raised from quarries, and used as a building material. And a sand-stone exists in considerable extent in others, as in Suffolke, &c. that is sometimes dug up, and made use of for common buildings, &c. In Cheshire, on the hills near Macclesfield, about Kerridge, a fort of sand-stone is met with, which is particularly well suited to the making of flags, and whetting tools, as well as sometimes to the forming of fletes, for which it was formerly much employed. Near Pott-Shrigley, also, a fine sand-stone is found, that admits of a good polish. The quarry has not, however, been wrought for fome late years, as from the extreme hardness of the ftono, the expence of getting it is very considerable. There are fome other quarries of excellent free-stone wrought in the fame neighbourhood.

There has been great abundance of free-stone wrought, time immemorial, in the low parts of the county of Perth, and quarries of a greater or smaller grained stone of this fort appear almost in every place, with the exception of the carfes. In the lowlands, and near to the eaftern fea, the pores and grain of it are greater; but as the mountains are approached, the pores are fefs, and the grain finer, by which thefe ftones admit a smoother polish. The quarry of Tul-lylan parifh, called Long-annan, affords a ftone of a very excellent quality. It has a white colour, admits of a smooth polish, and refists the influence of the weather. Some of the principal houses in that part of the country, as well as fome of the most magnificent public buildings in the capital of Edinburgh, as thofe of the Exchange, the Infirmary, and the Register-office, confift partially of this ftono, and thofe found at hand. And farther, in fome inftances it has been carried to the continent. But the quarry of Kingoodie, in the carfe of Gowrie, belonging to Mr. Mylne, of Mylnfield, is unquestionably the fmeft of this kind of any in the county. Altemining blocks in great number are raised there, fifty feet in length, sixteen feet in breadth, and three feet in thicknes. Such is the demand for this ftono, both at home and abroad, that four vessels are employed in exporting it from this quarry. The work is, however, on the de-
Quarry.

cline, occasioned by the act of 1794, which imposed a duty on flates, which, although trifling in itself, causes much grievance, vexation, delay, and trouble, in procuring coal-diffatches, &c.

Flag-stones and quarries for the working and preparing of all sorts of flags, are met with in all those situations where free-flag is found, and where it exists in rather thick flata, or layers of some depth, which are capable of being separated by hammers, wedges, or other means. In many places in the southern parts of the island, the flags raised from such free-flag quarries are of an extremely good quality, being used in very large quantities for many different purposes. Those of Cornwall, and Devonshire, in some counties, afford a good sort of flags. The flag-stone quarries of Shropshire, as at Grinfield, near Shrewsbury, about Bridgnorth, and at Corwudon-hill, near Bishop's castle, as well as in the Swinney mountain, &c., where alternate beds of fine white and red flate of this kind, of very superior quality and thickness, exist; that in the first of these situations, being twenty yards thick, affords flag-like, which are of a very useful nature. Free-stone flags too, of useful sorts, are met with in the quarries of some of the midland counties. And they abound much in many of the free-stone quarries of Lancashire, Yorkshire, and some of the other more northern districts of the country.

The quarries of this kind become flag-stone, and furnish the white, grey, and brown flate, wherever the flate lies in thin layers, or flata, which are able to be raised and separated from each other with convenience and facility. They exist in most of the above tracts, and are plentiful in some of them, especially those towards the north. The Lancashire and Yorkshire quarries, in many places, supply the white and grey forts in great abundance, and of good qualities. Those of Welfmoreland, Cumberland, and Northumberland, also afford them in many instances of a valuable nature. And they are equally good in the full more northern districts. There are numerous quarries of different colours of them in Clydefdale, Perthshire, Argylshire, and the county of Inverness, from which vast supplies are constantly raised for home and other uses. This sort of flate has, however, moystly the disadvantages of being very porous, heavy, lees durable, and of requiring more and stronger timber to support it, than some other kinds; being only fit for exposed climates and situations.

The quarries of the lighter and thinner kinds of flate, of the blue, green, purple, and other colours, formed from other sorts of flate, only exist in some particular districts. As those of Wales, the northern part of Lancashire, and the adjoining counties, and in a few places in Scotland. The flate quarries of the Welsh districts supply several kinds and colours in large quantities, and of good qualities, but the dark and lighter flates are the most prevalent sorts in most of them. In Lancashire the quarries of this kind are very numerous in the part to the north of the fands, as about Gouthwaite-common, Kirby-moor, Comiton-hills, and Tilberthwaite-fells, &c.; and from which very large supplies of the blue, green, and the dark purple sorts of flate are raised, and sent away for exportation, or consumed at home for different purposes. They are wrought, and the flate prepared in somewhat different manners in different places. The Gouthwaite quarries have the flate dug out from the side of the hill, and carried away. But in some on Kirby-moor, a level is driven through the ground from below, the metal being conveyed away by small four-wheeled wagons on iron rail-ways. Those about Comiton are mostly worked into the hills, and the metal raised and carried out from them. Some of the Tilberthwaite quarries are wrought by blisting the flate-flone, and collecting and carrying it out of them on flating roads, in small carts or trucks constructed for the purpose, the levels being below the hills, but not nearly so low as the bottoms of the quarries. Others are wrought by draught roads from the bottoms of them. One man will raise eighteen or twenty hundred weight of flate in one day, where the metal rises well, but lees in other cases. In some it is dug out by one set of men, split another, and formed into flates by a third, for which purposes, flat crow-bars, flate-knives, and axes are employed. The flate is divided and diffufered into three sorts, as flirs, second, and thirds, or London, country, and tons. In the first, or Gouthwaite quarries, the flate has a darkish purple, or black cast, and is worth from forty to forty-four shillings the ton. In the Comiton quarries it has a fine blue and green appearance, and is much thinner and lighter than the other sort. The Tilberthwaite flate, in some instances, splits very fine, thin, and light, but does not cover so far as the Gouthwaite and Kirby quarries. This flate is worth from forty-eight to fifty shillings the ton. In some quarries a sort of rent is paid per ton, on the flate which is raised, as ten shillings for the first, eight shillings for the seconds, and sixpence for the thirds. In others a certain rent only is paid for the liberty of the royalty, and not a tonnage duty. Those rents or duties on the workers of theses quarries, are probably higher than they will bear, and have enabled the Welsh flate dealers to undersell those of this county.

Welfmoreland and Cumberland, in some instances, afford good blue and green flates. In the latter, some of an excellent quality are gotten in the quarries of Borrowdale, and inferior sorts in some of the neighbouring mountains.

The county of Argyile, in Scotland, in some parts abounds with flate-quarries, as the tracts about Edfall, from which five millions of flates have for some time been annually sold at the rate of twenty-five shillings the thousand. Quarries of the same kind are also wrought in many other parts, with great benefit to the inhabitants.

Flate-quarries are formed in many parts of the highlands of the county of Perth, but none in the low. The flates in some are of a purple colour, in others of an azure blue, and in a few of a muddy, sandy, brown complexion along the cutters. It is well known where the different sorts are quarried. The veins of flate-rock seem to run from Drumlanzh in the parishes of Argestoll, in a north-east direction to Dunkeld; and may be traced beyond the limits of the county both ways. The azure coloured are the best metal, and rife of a greater size than any of the other kinds. Many of the buildings in different places are flated with this beautiful covering. Into the lower districts of the county, flates are imported from Edfall, and the other quarries on the west coast of the county of Argyile.

Quarries of grey flate exist in many different parts of the county of Inverness, in which the quality is very good, and well suited to the climate. In some places these flates are much preferred to blue ones, as the latter are more expensive in procuring, and though nailed on the roofs ever to firmly, are apt to be loosed by high winds, unless bedded in lime, which circumstance renders repairs difficult.

There are numerous quarries of fand and gravel to be met with in almost every district of the kingdom, which are wrought either for the purpose of supplying domestic uses, or those of repairing roads, &c. Those of the former sort, which contain the fand white, red, and yellow fands, are by far the most valuable, and wrought to the greatest extent, the materials being mostly dug out from the fides of banks and other places, and but rarely got by sinking the
the quarries into the more level parts of the ground, though this method is sometimes practised. The matters are commonly raised simply by digging and spades; and thrown into the carts, in many cases, from the quarries and pits themselves. Numerous quarries and pits of this nature exist and are wrought to a very great extent in the neighbourhoods of the metropolis, and most other large towns, all over the kingdom, for the purpose of sale for various domestic uses.

In the gravelly kinds, those quarries which abound with the sharp, coarse, flinty, and pebbly sorts, are the most proper and beneficial for the making and repairing of all sorts of roads and carriage-ways. They are occasionally formed by working into banks and steep places, but more frequently by openings in the plain surface. Their depth is sometimes considerable, the materials being raised after being screened, the work, of course, very laborious and troublesome. In other cases, the carts are filled from the quarries or pits without much difficulty or trouble.

Quarries of clay-lime, fine-tiles, fitchie-tiles, and some other sorts, are found of good qualities in different districts. In Gloucestershire they have quarries of blue-clay-lime at different depths, lying in beds of the same coloured clay, disposed in layers of from four to ten inches in thickness. The fitchie in new quarries is estimated by the effects which the atmosphere has upon it from some exposure. The best sort is a very useful material for several purposes. Quarries of fitchie-tiles principally exist, and those articles are raised from them, in different part of the Cotswolds. The best are prepared about Miserden, Beverstone, Charlton, and Hampton-field, the colour of which are yellow or grey; but another sort, which is red grit, is dug up about Iron Acton, and some other places, but which is less valuable.

There are quarries of fitchie-tiles in many parts of Lancashire, but the best are obtained from those about Rainford, where they are well wrought and prepared for use. In several other districts, quarries of different kinds of whetting-fitchie likewise exist, and are wrought to advantage.

Ochres of different kinds are met with in different places in quarries formed for the purpose of raising them. In the county of Devon, formerly large quantities of various shades between red and yellow, were raised and manufactured in those about East-down. Umber, in the parish of Combermartin, exists in a pretty large body. The working and preparing of these are, however, now much less attended to than heretofore.

In Suffex there are quarries of red ochre about Graffham, and in various places contiguous to the sea, as near Chilham, &c. where much is raised, prepared, and sent to London. Ochre quarries also exist in many counties more to the middle and north of the kingdom, from which great quantities of this substance are procured and prepared for use in different sorts of arts and manufactures.

Quarries of plumbago, or black lead, are likewise occasionally found and wrought, in different situations, in different districts of the country. This substance has been met with and raised near the borders of the Bovey river, in Devonshire, in some quantity, and prepared to be sent to Exeter for sale. Quarries of black lead are also found and wrought in Borrowdale, in Cumberland, near to the town of Keswick, to some advantage. And they exist in some of the middle tracts of the island, affording great benefit to the proprietors of them. In the county of Inverness, there are some appearances of black or pencil lead about Glengary, but they have not yet been turned to any useful account.

In some districts, in the middle parts of the country, quarries of calamine, or lapis calaminaris, are met with, and much of this substance raised from them to great profit. It abounds in the Mendip-hills, in Somersetshire, about Rowbarrow, Shipham, Winchcomb, and on Broadfield-down, &c. It is sometimes found within a yard of the surface, and seldom wrought deeper than thirty fathoms. In some places its quality is excellent. It is present in other neighbouring mountainous tracts, and raised with equal advantage.

Quarries of gypseum present themselves in many different parts, and are wrought in some with considerable benefit. In the county of Devon, it lies between Ifrata of red-lime, marle, and chalk rubble, about Salcombe, Brauncombe, and Bove, being useful for various purposes. Gloucestershire and Derbyshire have quarries of this nature, where there are fine beds of it. Tho' of Ault Cliff in the former, have it not so good, however, as that which is met with in the latter county. In Nottinghamshire it is of an excellent quality, especially that got near Newark and at Redhill. Cheshire has some, but not turned to much account. Wiltomrwell and Cumberland have good quarries of it, in some places, where a great deal is gotten up, and made use of. And it abounds in different parts of the county of York, where it is raised to advantage.

Marle is an article that is met with in pits and quarries in a variety of different situations, and of several different kinds and qualities. It is found and dug up for use in many places in Suffolk, and the counties more to the centre of the country; but it prevails in the greatest plenty in the county of Lancaster and some others, in which it is raised or worked out from large openings on the sides of hills, high banks, or in the plain surface, and cut thickly upon the land. The getting or digging of the material out of such places, is usually performed by means of strong iron mattock, crows, spades, and wooden spiles; large pieces being in some cases forced down, not without danger to the workmen, by driving in the spiles or piles from above. This method is called falling. The work is extremely severe, and commonly done by the rod. The large clods thus forced down, break into small pieces, and are then filled into carts for the purpose.

Shell-marl, though it is not much attended to in any part of England, is frequently met with and dug up from various parts of Scotland, and employed on the land in great quantities, with much success. The pits and quarries of this sort are commonly wrought with much more facility than those of the others.

Pipe, and other kinds of fine clays, are dug and raised from a fort of pits or quarries, in large quantities, in many different counties. Near Wear Giffard, in Devonshire, much of the firr fort is dug and sent coastways, though not in such quantities as formerly. Brown potter's-clay is also raised and sent away in great abundance from the neighbourhood of Fremington. These sorts of clays are likewise found in much abundance in Berkshire, and still more fully in some of the midland districts, where the pits of them are wrought to a vast extent. They are articles of great importance and utility in several sorts of manufactures, and for which there is great demand in many instances.

Alum-earth is a kind of stratified matter, which is met with and raised from pits and quarries in a number of different situations, and various parts of the kingdom. In some they are wrought to very considerable extents and advantages, but in others in far less degrees, and with much less success.

The Ifrata of this earth are dug and got up in different manners
manners under different circumstances, but mostly by means of strong crows, picks, and other tools of a similar kind, being wrought in somewhat the same method as in the cafes of marie. The bushefs is usually executed by common labourers.

Fuller's-earth is another material of this nature, which is dug out of the ground from pits and quarries at different depths in several parts of the country. In some it is very abundant, and of a rich good quality, as in those of the middle and more northern parts of the island, forming an article of great use and demand in several branches of bushefs. In others it is of a much less valuable nature, being far less in request. That which is found about Tillington, in Sufex, is consumed in the neighbouring fulling mills. The mills of this fort in Yorkshire, and other parts also, consume immense quantities. The material is raised from the places in which it is found in much the same way as many other earthly substancess, but it seldom requires so much digging, as it is a far less hard matter.

Fuller's-earth was formerly got up from pits and quarries in the neighbourhood of Maidstone, in Kent, and much ground wrought over; but the beds of sand by which it is covered are of such depths, as to render the works of little value or importance.

Quarries and pits of mineral-peat-earth are found in some districts, and much of the material dug up from them, and made use of when prepared upon land. The vale of Kennef, in Berkfhire, contains vast quantities of it, as well as some other parts. It is a stratified substance which is dug from under the surface at the depth of from one to fix feet, laying below strata of small hells and calcareous matter. In raising it, a peculiar kind of spade is made use of, which cuts it in long pieces, something like foap, which, when dry, are burnt into ashes and laid on the land. This substance is found to contain the oxys of iron, gypsum, and the marizites of sulphur and potash, in the proportions of forty-eight, thirty-two, and twenty parts to that of one hundred.

It is suggested by the writer of the work on "Landed Property," that in most mountainous districts, and many low fenny counties, immense collections of vegetable mould or peat-earth lie in a state of neglect; even in places where they might be converted to valuable purposes; not only as sources of fuel merely, but as manure, either using the vegetable matter in its raw state, or after being reduced to ashes. In all these situations it might be readily dug up from different places, and applied to different uses in each of these ways, the pits or other spots containing it working in a very easy manner. The ashes of it are only employed on any large scale in the above county.

Culm, coal, and cannel, are articles of the fuel kind, which are found in a vast number of places, all over the kingdom in pits, mines, or quarries, and which are of the greatest importance in many of them. Speaking of coals, the author of the work on "Landed Property," considers them as rising in the minds of most men, far superior to most other productions and subterraneous matters, whether they are held in the light of agriculture, manufactures, or national defence. It is asked, if it were not for the colliers of this country, how many hundred thousand acres of its land, which are now appropriated to cultivation, would be required for the production of fuel? How many manufacturies, especially those of iron, which are so very valuable to civilized society, would be cramped, retarded, and stopped, in their progress and operations? And how many hardeen would be wanting to its navy? Surely, in his opinion, an indigenous production and material, on which the prosperity of the country so greatly depends, is entitled to the guardian care of its government; to avert the present expenditure, and the probable stock which is remaining. Let us not, it is remarked, play the spendthrift, and, by the follies of a day, entail centuries of want on generations to come, and the curses of millions on the memory of the present times.

In endeavouring to find these sorts of substancess in parts where pits of them have not yet been wrought, the searching, it is supposd by the same writer, should, in general, be done by the land proprietors of the particular places, in a conjoint manner. There are, however, certain instances in which individuals may prosecute the search with propriety, and in the most beneficial manner. In doing which, the principal things to be guarded against are those of misjudgment and imposition. Hence the necessary prudence of endeavouring to procure persons of skill and integrity for making such searches; which are, in the first place, to be attempted by a close investigation of superficial appearances, and then where those are favourable in their nature, by the use of the boring rod or tool. It is supposd that, at present, there are none who are equal to such undertakings, except those who have been long conversant with the bushefs of coal-work; men who have an interest in the existing colliers or works of that kind. On this account it is thought to become a matter of common prudence, in a given situation, to endeavour to procure an undertaker or overseer from a distant work; or such a one as can have no counter-interest to that of his employer; and then, closely to connect and bind them in one common interest. After having had different occasions for considering the subject, and for belowing no small thought upon it, the writer is of opinion that the most eligible plan of proceeding, in such cases, is that of agreeing with an overseer, or undertaker, to pay him reasonably, but not extravagantly, for his time, and for his actual expenses in prosecuting the necessary searchs; and, further, to agree to give him, in the event of success, a reward sufficient to call forth his exertions; such reward to be payable, not on finding coal, but whenever the work, to be established in conformity of the discovery, shall have cleared the amount. In this way the proprietor will feel himself secure, while the person employed has the most powerful stimulus to industry, attention, and the accomplishment of the object of the undertaking.

Culm and coal have been met with and wrought in some degree, in Devonshire, Sufex, and some other parts of the southern parts of the island; but they exist much more plentifully in the midland and more northern districts, as well as in some places in Wales and Scotland. In Gloucefshire, coal abounds in most parts of the forest of Dean, and its vicinities, and probably to within a small distance of the county-town, as at Newent and Pantley, where pits are established. Those of the forest trackes are very numerous, but not fully wrought for want of sufficient draining. Pits of this kind also exist in many places, in the lower vale part of the county. In this district, however, the coals are no where of the best quality.

In the counties of Salop and Somerset, coals also prevail very much, various pits of them in both, being wrought to considerable extent. Those in the northern part of the latter district, have strata of them which form an inclination of the plane of about nine inches in the yard; and are nineteen in number. They are seldom wrought where less than fifteen inches in thickness, but they vary from ten inches to upwards of three feet. The working is performed at considerable depths, especially since the establishment of improved machinery; and other means for raising them. The coal
coal is of the first quality, being pure and durable in burning, and from its firmness, largeness, and strength of grain, capable of being conveyed to any distance without injury. At present the quantity raised in these pits, is from fifteen hundred to two thousand tons weekly, but much greater supplies could be afforded, if they were wanted. The works are twenty-fix in number, some of which afford a good profit.

The pits in the southern part are upon a more limited scale of work. In them the strata of coal form an inclination of the plane of from eighteen to thirty inches in the yard; but in some it is destroyed, and they defend in a perpendicular manner. There are, in number, twenty-five, which are in thickness from six inches to seven feet, being rarely wrought under eighteen inches. The depth of working is middling but will be increased. The quality of the coal not the bulk, but tolerably good. The quantity now raised from these pits is from eight hundred to a thousand tons in the week, which might be easily extended. The working profits are by no means great. There are pits in other parts, but they are not many, nor much wrought.

Against the apprehension of pits of this nature being exhausted or worn out in these places, it is contended that more than triple the present quantity is capable of being raised from the works already carried on, and that this increased quantity might be supplied for several hundred years to come.

The works and quantities of coals contained in the counties of Stafford, Derby, and Nottingham, are likewise very great, and mostly of good kinds; pits of them being carried on in many places to vast extent.

Chestre, too, is a coal district, in which a great variety of works for raising it are established in different parts, and much of it, which is of a very good quality, gotten up. The strata of coal here in many cases are several feet in thickness; about Wirral the seam is five or six feet thick, and the works extensive under the channel of the Dee. In some works the beds of coal lie at the depth of from seventy to one hundred yards below the surface of the ground, and are of different thicknesses to ten feet or more.

In Lancashire, coal of good forts is most abundant. The beds of it run across the county in somewhat three different parts, as towards the north, nearly in the middle, and on the north-east part. These in the two first are of considerable breadth, and thicknesses in different parts, but the third is much less broad and very thin in many places. They all run, in some degree, from the north-east to the south-west, constantly keeping somewhat the same direction, though occasionally branching out in a lateral manner to some extent. The works on each of these different lines of coal strata, especially the two most towards the south, are very numerous, and, in different instances, of very considerable extent. There are some also established on the northern line, but they are of a far more limited nature. The layers or strata of the coals are of various widths, from a few yards to a very great distance, and their depths or thicknesses from a few inches to fix or seven feet. They lie at very different depths from the surface of the earth, according to circumstances and situation; on the eastern side of the county they sometimes nearly appear on the top of the ground, while in the middle, and towards the south-west, they are often a considerable number of yards deep. All about most of the large towns in the southern parts of the district very extensive works are established, where immense quantities of coals are raised for home use, as well as being lent coalways, and, in some cases, for exportation. They are a sort of material which is of vast importance to the manufacturingstate of the county, and which contributes greatly to its prosperity. The quantity is so great, when considered as a whole, that they would seem to be almost inexhaustible.

The cannel coal, which is a sort that has some resemblance to fine black marble, is principally found and raised in the tract about Haigh, near Wigan, which is not more than a few miles square. It lies in pretty thick strata, at the depth of from five to seven or eight yards from the surface. It is of a very fine, hard, inflammable quality, being got up by sharp picks, often with considerable labour, and for which there is much demand, for domestic use, in the neighbour-
AQUARY.

An acre of ground contains 4840 square yards, by which, multiplied by the thickness of 6 yards,

there gives 29040 cubic yards in an acre.

From which deduct 3d for waste and the parts or pillars necessary to be left in working,

there remains 19360 cubic yards to be wrought.

And as three cubic yards of coal, when wrought, afford a Newcastle chaldron, therefore

19360 = gives 6453 Newcastle chaldrons per acre, divided by 3.

The coals exported yearly from the rivers Tyne and Wear, with Hartley and Blyth, amount to about 825,000 chaldrons, which, with the home-consumption of the two counties of Northumberland and Durham, will make the quantity of coals raised yearly about 1,000,000 chaldrons.

And the chaldrons raised yearly

1,000,000 = gives 155 acres nearly per year, cleared of coal fixed yards thick.

And by estimating the breadths occupied by the caking coals to be on the average eight miles broad, and twenty-five miles long in the two counties, it is found that there will be about two hundred square miles, or 128,000 acres of coal proper for exportation.

From Newcastle

510,000 chaldrons.

Sunderland

315,000 ditto.

In all 825,000

Then the whole area 128,000 = 825 years. The time yearly divided by

155

before this space will be wrought out.

It is, however, suggested, that there are some reasons to suppose that a thickness of seam equal to six yards will not be obtained all over an extent of two hundred square miles, probably not more, on an average, than four yards; in which case the coal will be exhausted in five hundred and fifty years. And if the aggregate thickness of the seams to be obtained should prove only three yards, then little more than four hundred will be the term of continuance; but it is probable, it is thought, that before the half of that time be elapsed, the price to the consumer will be considerably increased from the increased expense of obtaining them, and the increased length of carriage from the pits to the rivers; this last, it is presumed, may be reduced in some situations, by adopting canals instead of waggon-ways, which, it has often been wondered at, have never yet been attempted. From this investigation, it is suggested, that the apprehensions of exhaustion are not so chimerical as they have been supposed and represented to be by some persons. When, however, the vast extent of the working and unworked tracts, in the different parts of the country, are considered, there cannot be any grounds for fear, in this respect, for a vast length of time yet to come.

Pits, some what of the quarry kind, are wrought in one district of this country, that of Chelmsford, for the raising of rock salt, in some of which large quantities of this material are procured, from different depths, and different thick-nesses of the strata of it. In the getting of it different means are employed, as those of blasting, picking with implements, for the purpose of roofing, the ufing of horses, and machinery wrought by steam, for forcing up the sub-

stance, and some others. The digging, raising, and working of this article, employs a great number of labourers, and it is of much importance to the county in many points of view.

But though the art of material is found in several different parts of the county, pits, or shafts of it, are of great importance in the vicinity of the town of Northwick. This arises from the great many different causes, but principally from that of the want of water-carriage for the conveyance of the material from them. The number of pits or shafts, which are at this time in work, for the purpose of raising this article, are about a dozen. They are by much the most commonly made in something of the square form, being secured on the sides by means of strong timber, but they have occasionally a round form, and are walled on the sides with bricks.

The beds of this material, that are to be raised, are wrought at various depths, the deepest being in general the most pure, and they vary equally in their thickness and directions, as suggested above. In some cases the beds are of the greatest thickness, the more they approach the north-east, decreasing in a gradual manner, in their course to the south-west; and in some instances they incline from north-west to south-east, dipping at the rate of about three feet in twenty-seven or thirty.

The first, which are passed through in getting at and working the rock-salt, lie in a very regular manner, and consist, in general, of a hard clayey substance and a foot of gypseous material in mixture in various ways and proportions, that of the latter kind being the most predominant as the pit or shaft approaches the rocky saliferous substance. In working, the clayey matter is designated by the name of metal of the several different colours belonging to that foot of substance, and the other material by that of plaffer. These first are mostly of a solid compact nature, but occasionally broken in particular places, when the metal is termed flaggy by the workmen.

In the business of working the pits, and raising the rock-salt, the rocky beds are reduced into pieces of proper sizes for the purpose, by means of blowing them with gunpowder, and those of splitting and dividing them with hammers and proper wedges for such uses; a good secure headway or roofing being constantly provided in the first place, to the opening from which the salt-rock is to be taken, which is effected by the use of small sharp picks, carrying on the work in a plain simple chambering manner.

The workings are sunk from these chamberings to different depths, as the nature of the beds of rock, and the quantity of the purer kind of rock-salt, or Prussian rock, as the workmen term it, may direct; but commonly about fifteen feet. Occasionally the roofs of the pits or shafts are supported by considerable square pillars disposed in a somewhat regular manner, but in other cases they are wrought out in a sort of long openings, according as the workmen are inclined.

In getting the rock-salt, the workmen are paid by the ton at the rate usually of about two shillings, they finding the gunpowder and other tools.

In raising the salt from the pits or shafts, horsess were formerly entirely made use of, but within these few years, recourse has been had to the improved steam-engine, as already noticed, though it is not yet generally employed at every pit. See Rock-salt, Rock-salt Pits, Salt, and Salt Brine Springs.

It is evident from the above account, that in whatever way they are considered, the quarries of different kinds in this country are of very material importance to its prosperity.
QUARRY.

prosperity and convenience; contributing largely to the carrying on of different sorts of works and improvements. Without them much useful labour must be wholly at a stand; a variety of necessary business will be incapable of being carried on; and the effects of it upon various arts and manufactures, be much too serious to be thought upon. In short, the numerous substancés of different kinds, which are taken from the bowels of the earth in this country, constitute one great source of our national wealth and prosperity.

Quarries, Pits, &c. Draining of, the proper, most convenient, and appropriate means of rendering all such forts of works dry, free from water, and in a fit state to be wrought with ease and advantage. In the effectual performance of all kinds of undertakings of this nature, there is occasion for the application of the same principles, which are spoken of and explained in considering the nature of draining land in general, and the particular manner which is necessary to be pursued in the practice of spring draining. See Draining of Land, and Spring-Draining.

There can be no doubt, indeed, but that the having recourse to such principles, and the modes of practice resulting from them, will be equally expeditious, beneficial, and successful, as well as in many situations of very material importance, in the various cases of this fort, as in those which have been mentioned; by leading to and introducing the most ready and easy means of diminishing the quantities of water, which are frequently met with in the course of working them, and which not unfrequently obstruct and hinder in a very high degree, but sometimes wholly put a stop to the work which is carrying on in them. Such, at least, is very often the case in quarries of the free-bone, lime-bone, flag-bone, marle, and other kinds, as well as in pits of the coal and other forts. The want of this fort of knowledge, of course, is one great cause why such a number of quarries and works of that kind, in different parts, often lie altogether, or for a great length of time, in an unworked state; which might otherwise be wrought to very great advantage.

As it is now well understood, that most springs and subterraneous collections of water are formed and supplied from such grounds or lands as lie higher than that of the places where they are found or met with, which, on account of their being of an open or porous nature, admit that of rain and other sorts of moisture to filtrate and pass freely through them, which sinking and descending to very great depths, through such open materials of the rocky, sandy, gravelly, and other loose qualities, before it becomes impeded and obstructed by some fort of impenetrable stratum or layer of an earthy or solid flinty nature, such for instance as those of pure stiff clay or compact rock; it may happen, that in many such caves, in sinking pits or shafts for bone, coal, or any other kind of subterraneous material near the bottoms of hills or high grounds, beds of quicksand will be met with, and dug into, which are so full of water, that to pass through them becomes a most troublesome, difficult, and expensive piece of work, and sometimes impossible to be performed, but which, from knowing that the water proceeds from the porous ground that lies above, it may often be practicable to intercept and cut off the greater part of the water, before it reaches such sand beds in the quarries, pits, and shafts, by the means of boring into and tapping the water at the tail of the banks of this nature, provided that the ground naturally declines lower than the place where the sand is found in the quarries, pits, &c., and the whole or most of the water be drawn off, and diverted from them at a comparatively trifling expense to that which is employed as the common remedy in such caves and circumstances.

In order to accomplish this intention, it will be necessary, in ascending from the quarry or pit, to carefully examine and ascertain, if at any place higher on the declivity, any porous stratum, bed of rock, sand, or gravel, tail out, which may conduct and convey the water contained in it to the sand bed, which is below in the works; and where any such bed is found, to cut or bore into it in such a manner as to form a drain, that is capable of carrying away the whole or the greatest part of the water, and of course to clear, or diminish the quantity contained in the quarry or pit, which would otherwise have continued to descend through such porous subjacent or beds, and have continued to fill the pits, or quarries and pits.

But although this part of the business may have been accomplished, and the supply of water from the higher ground entirely cut off, a sufficient quantity to injure, hinder, and inconvenience the working of the quarries or pits, may yet continue to drain and ooze from the sides of the sand beds, notwithstanding they should happen to dip towards the lower ground, in which cases, however, that water may readily and with great ease be commonly drawn off at some particular point in it.

In order to effect this, and thereby remove the inconvenience of this filtrating water, in descending from the quarries or pits along the declivity, it should be endeavoured to discover and ascertain, at what particular point or place in the low ground, the sand terminates or tails out, which is most easily accomplished by means of proper levelling; and if there should be there any appearance of the waters having a natural outlet, it may, by means of making in it a deep drain, be more readily and effectually drawn off and removed; as springs, for the most part, naturally pass and flow through narrow, winding, convoluted openings, or perforations; of course, whenever the orifices or passages are opened, enlarged, or made lower than before, the discharge of water becomes greater and more expeditious.

Where, however, there happens to be a deep impervious layer or covering of clay, or other matter of a similar nature, placed above or upon the termination or tail of the sand, the drain need only be cut down to it or a little way into it, as by means of boring through it, or the remaining portion of it, a ready and easy outlet or passage may be given to the whole of the water, that may be contained in the sand-bed or other porous stratum.

This mode of draining quarries and pits may often be of great utility, advantage, and convenience, as it will also, in a great degree, remove, or at any rate relieve, the trouble and difficulty, that would afterwards have attended the sinking the quarry, pit, or shaft; as the water thus drawn or cut off, must of necessity diminish and reduce the quantity, which would have been found at a greater depth, the fame body of it probably passing downwards from one stratum to another, as far as they continue to be porous, or capable of admitting it. Therefore, it is of very material importance to drain and lay dry all such ground as is situated higher, but contiguous to quarries, pits, or other deep subterraneous works of the same kind, for the above stated reasons. And it may, in general, be accomplished with but little trouble, difficulty, or expense, by adopting the same principles, and the same means.

But in regard to the removal of the water found and contained in the bottoms of such quarries, pits, or deep works, it must be drained off and got rid of in quite a different manner, as the level of the ground may probably be, or decline, nowhere lower than the mouths or openings of such quarries, pits, etc.
pits, &c.; as it is solely and particularly on the supposition, and in such cases as where the direction of the different strata and sand-beds have a dipping position with the natural inclination of the surface of the land, or lie nearly horizontally, that the method of proceeding which is stated above is practicable, or capable of being employed with any sort of advantage. But should they, for instance, lie in a reverse or contrary direction, there is but little possibility or chance of accomplishing the object, the removal of the water, unless by discovering or hitting on their terminations, somewhere on the opposite sides of the hills or elevations, which in some cases may very nearly or exactly be found out, by ascertaining the precise inclination or direction of the materials of the quarries, pits, &c. and by a careful and exact use of the level. But this will be much better comprehended, and a more clear, full, and perfect notion of its nature be afforded, by the section figure in the plate on draining quarries, pits, &c. in agriculture, as given by Mr. Elkington, in his work on that subject.

This is the manner which is to be pursued in preventing the effects of water, or cutting off that which is met with in sinking the quarries, pits, shafts, or other similar works, before reaching or arriving at the stone, coal, or other sort of material that may be wanted; but that which is found in the bottoms of these different kinds of undertakings, or which proceeds from the rocks or their sides, or in other ways, in the course of working them, is commonly got quit of by means of some sort of machinery, as that of the engine or other kind of pump, in order to afflict in working of which, the water gained by cutting the drains already noticed may be particularly useful, especially where the usual stream for that purpose is insufficient in favoring the great expense of working such machinery by the power of steam. But without the aid of a natural stream, which is capable of being converted to this purpose, it is rarely possible to find, by means of drains, or in any other way, a quantity of water sufficient to drive such weighty machinery, in a situation of proper height, to have the full and necessary command of it. However, in many cases it may be an acquisition of great utility and value. It is explained at fig. 2. in the same plate.

In some situations, where a full and proper command of water can be had, and where the entrance to the quarry, pit, shaft, &c. is also suitable for the purpose, the use to which it may be converted and applied is still more important and advantageous, as the driving of machinery for bringing out the various kinds of materials, and at the same time working an engine-pump, in order to clear the works of the subterraneous water which flows from the cavities of the rocks, which are met with in working these sorts of pits, &c.

It has been remarked in Mr. Elkington's work on draining, in these cases, that the Duke of Buccleugh's coal-works, near Langholm, in the county of Dumfries, afford a striking example of this, as well as of the superior powers of water and machinery, when properly combined, where a command of the former can be had, and where the latter is constructed on proper principles, and conducted with that care and ingenuity which are requisite in such difficult undertakings.

In working quarries of lime-stone, free-stone, and other sorts of materials, it is not unfrequently happens, that, at a certain depth, part of the rock or other body, which contains the water, is hit upon, by which they are soon so filled with it, as completely to put a stop to the work proceeding any deeper, where the bell and often the greatest part of the stone is situated. In all such cases, the most usual remedies have been, either the erection of a wind-mill pump, to draw out part of the water, as the whole cannot be taken away by such means, or the opening of a new quarry or pit contiguous to the other, which at the same depth most closely meets with a similar obliquity, or the bringing up of a very deep cut, often at great expense, under the level of the water, from the nearest declivity or hollow that can be met with. However, by the following method, all quarries of lime-stone, free-stone, marls, or other materials of the fame nature, which are liable to such sort of obstruction, may be completely and effectually cleared of the water at but little expense; while, at the same time, the drain which is made may serve the double purpose of that, and the laying of the wet ground, caused by the spring contained in the rock, which is found contiguous to it, dry.

There commonly lies, immediately under the rock, a bed of strong, stiff, retentive clay, which absorbs all the water received and retained by that rocky stratum, and which being, at the same time, bound round on each side by a covering of the same kind of clayey material, or other fluff earthy substance, is not able to discharge itself, and of course constantly remains or stands full in the rock, so as to prevent the working or taking out the stone from the bottom.

In such cases it is necessary, in the first place, to endeavour to find to what side the rock dips or inclines, which, in general, may easily be ascertained by the appearance of the surface, in examining the surrounding ground, and the aid of a proper level. When this has been discovered and fully ascertained, a suitable drain must be cut through the clayey covering to the rock, by which the water will be drawn off, which, for want of a proper outlet, formerly stood up in the hollows and cavities of the flone stratum or body. This is further and more fully explained by figs. 3 and 4, in the same plate.

But, in some cases, this sort of evil or inconvenience may be removed and remedied in a different way. As it frequently happens that a bed or body of the same stone, which has a close, compact nature or quality, is found lying under one which has a more open porous texture, with bull's heads and cracks in it, that are admirably of water, which obstructs and keeps up the water in the upper bed or layer, in such a manner, that not any of it can pass or filter through it to an inferior, or still deeper open stratum or bed; and on sinking or cutting through this compact bed of stone, another layer is met with, which is of so open and porous a nature, as to admit the reception of any water from the above one, which may come upon it.

And sometimes a bed of gravel or sand is found under that of the close flone, which being still more capable of absorbing or taking up any water that may be let down to it, is far better and more properly suited for the purpose of clearing the upper bed of stone from water, than an stratum of open flone itself.

Therefore, when this is discovered and ascertained to be the case, and the water is kept up by the second bed of stone, as to be injurious and hurtful to the working of the upper bed, and which will be equally so in working the second; the work may be greatly freed and relieved by boring through the close bed of stone, and letting down the water into the more porous one below, or into a stratum or body of dry sand or gravel, should there be such a one underneath it. But in place of boring, the sinking of small pits through the close flone is a more effectual method of letting down the water, though a much more difficult one in the execution.

The methods of digging and boring, even in the bottoms of quarries, pits, and shafts, where pumps and other machinery of the same nature are made use of, as has been noticed above, may, in some cases, not only be practicable, but advantageous for letting down the water which they contain into an inferior open stratum.
That of boring has been practised with complete success in the case of a colliery in the county of York, which had been wrought many years, and in which the water was raised about sixty yards by a steam-engine; the proprietors of which, on boring down from the bottom of the pit next to the engine-pit, to the further depth of about ten yards, in order to ascertain the depth or thickness of a seam of coal, which was supposed to lie below those then wrought; the workmen, on taking out the boring rods, found that the water from the works, which usually ran across the bottom of this pit to the engine-pump, now ran down the holes they had made. And that the steam-engine pump, on being set to work, contained little or no water, it having escaped through these holes, and continued to run through the same ever afterwards, rendering the pump useless. It is remarked, that this influence of water at so great a depth from the surface, finding a passage at a further depth of ten yards, or less, and immediately below, is extremely singular and striking in its nature. The situation was much higher than the nearest contiguous valleys, or the level of the sea. Trials of this sort can seldom be made, therefore the cafes are rare, uncommon, and curious. But in extensive tracts of level land, where lakes or morasses have been formed, and which cannot be laid dry by cutting open drains, or driving levels through rocks, except at an expense for which the lands, when drained, would never compensate, the above instances warrant the trial of experiments with boring rods, which, if not attended with success, can be made at little expense.

In the county of Lancaster, on the town of Ormskirk, as well as in some other parts, flume quarries are cleared of water exactly in the manner which has been already pointed out, but which fig. 5. in the plate will explain much better.

The success of the practice has likewise been farther shown by the late T. Eccleton, esq. of Scarfribrick-hall, an ingenious and extensive proprietor of land in the same neighbourhood, who remarks, that in flume quarries thereabouts, wells or pits are occasionally sunk to the open bed, which have proved serviceable. This mode was practised in a flume delf near the above town in a very beneficial manner. But in order to lay the delf more effectually dry to a greater depth, Mr. Elkington, on viewing the surrounding ground, marked out where he thought the rock terminated, or tailed out, and at the lowest level let out a drain to be cut and carried up to the rock, part of which work has been executed, and a very considerable flow of water comes from it; but on account of its great depth, sixteen feet, the whole will not be drained before he has seen the work again. The drain he has thus laid out is about ten feet lower than the bottom of the flume quarry, and when completed, will lay the head or body of flume dry lower than the present floor. All rocks, for the most part, where they terminate, are succedued by broken loose flones of the same nature as the rock, and they are frequently, nay almost always, succeeded by sand, which, when in a thick bed, and of a running nature, such as quicksand, often cause great expense in cutting through to the tail end of any rock. This is more fully explained in speaking of the manner of draining in hilly lands, and where the rocks are of a mixed nature. See Springs-Draining.

Therefore, in all such cafes as this, where there is any danger of meeting a quicksand, boring or linking pits through the bed of close flone, is by much the most advisable, and at the same time the least expensive method that can be pursued.

The situations of marle pits are for the most part such, that they require very extensive cuts to be made through some parts of the surrounding banks or sides of them, in order to carry or convey off the superabundant quantity of water which prevents their being dug or wrought to advantage. This business might frequently be effected in a much less troublesome and expensive manner, by the method of letting the water down by means of sinking pits or openings through the retaining and upholding stratum underneath the bed of marle, into some absorbent porous body of materials lying still deeper, which is capable of receiving it. Where the space of ground that is occupied by the marle is of considerable size, several pits will be required, in order to effectually carry off the water; and where it is necessary that they should be so deep as to be in danger of falling in, they ought to be walled round the sides, or filled up to near the top with loose flones, through which the water can settle and find its way. And any such crofs drains or cuts as may be necessary for the purpose of collecting the water must be so formed and conducted as to flow into the pits. But in many cafes the water may be removed and got rid of in a still more easy manner, especially where the situation of the ground is favourable and fitted to the purpose. In instances where the surrounding banks decline or fall on the opposite sides, lower than the water, by cutting drains into them, and boring with an horizontal auger into the tails of the strata containing the water, it may be drawn off and brought down to a level lower than that of the bed or body of marle. And as this water is not unfrequently supplied by a spring which rises in some part of the higher ground, and descends into the place where the marle is found, it will be necessary, in all such cafes, to cut off the source of it, and divert the flow of water into some other channel; as by that means the quantity of water below will be lessened, and more easily and readily carried off by the pits or drains which may have been formed.

Mines and shafts, for the purpose of raising different sorts of metals, are often much impeded, or wholly prevented from being wrought by the water which is brought into them from a distance, by various kinds of mineral strata. In many such cafes, the water flowing in this way may be intercepted, by making cuts up to the lowest banks of them, from some neighbouring water-courses, or other convenient outlet, and then boring or digging pits in the bottoms of such cuts, when the metals to such depths or levels will be rendered free from water, and capable of being wrought. This will, however, be more amply shown in considering the manner of draining, in some cafes of wetness, caused by springs arising in this way. See Springs-Draining.

In removing the water, or freeing the bottoms of quarries and pits from it, where machinery is required, the writer of the work on "Landed Property" has remarked, that in cafes where shallow-drains are found to be impracticable, well-drains and pumps become necessary, and are the most proper; as they may be wrought by water, where streams can be conducted to them; or by wind in high exposed situations; or in works of confluence, where fuel is moderately cheap, by small steam-engines. However, in instances where large bodies of water are required to be raised and discharged at the height of a few feet only, marsh-mills, such as are made use of in low marsh-land districts, are found the readiest and most useful kind of machinery for the purpose.

In some cafes of this nature, the bottoms of quarries, pits, and mines, may be cleared from water, simply by forming openings into them from some parts of the neighbouring ground where it falls lower than the levels of them, at sufficiently short distances, without any other more expensive works being undertaken for the purpose. This should always be fully considered before any means are resorted to.
for laying them dry, as it may occasionally be the saving of much labour, trouble, and money.

**Quarry**, in Glassery, a pane, or piece of glafs, cut in a lozenge, or diamond-form.

The word seems formed by corruption, from quarrel, (which fee) ; unless we will suppose it to come immediately from the French quarrer.

Quarries, or quarrels of glafs, are of two kinds ; viz., square and long, each of which is of different sizes, expressed by the number of pieces which make a foot of glafs; viz., 8ths, 10ths, 12ths, 15ths, 18ths, and 20ths; but all the sizes are cut to the same angle, the acute angle being \(75^\circ\) and \(25^\circ\) in the square quarries, and \(75^\circ\) in the long ones.

**Quarry**, in **Falconry**, is the game, or fowl, which the hawk is in pursuit of, or has killed.

**Quarry**, among **Hunters**, is sometimes used for part of the vifcaera of the beast taken; given by way of reward to the hounds.

**Quarry-Cart**, a name commonly given to that fort of cart which is principally employed in the work of quarries, and which is generally of a low, compact, strong kind, in its nature, form, and manner of construction, in order to sustain heavy weights, and receive them without difficulty, or the danger of being destroyed. Carts for this purpose should always be made of well-seasoned wood, be well put together, and have sufficient strength of timber in those parts where the main free of the load is placed. See **Cart**.

Some quarries counties have well-formed carts of this nature, as many of those towards the northern boundaries of the kingdom.

**Quarry- Waggon**, or **Truck**, a small carriage of the low truck kind, which is much employed in the bufinets of quarries, especially those of the slate kind, for the purpose of holding and conveying the rough materials, which have been blown from the large mally rocks, or separated in other ways, out of or from the quarries and pits in which they are situated and contained, to the places where they are to receive their different preparations and shapes.

It is formed and constructed on a frame somewhat similar to that of the common barrow, and mounted on two low light iron wheels on the fore part, having two feet behind, projecting from the frame, bent something in the manner of the letter S, and of sufficient length to let it stand or rest in a horizontal position while it is in the act of being loaded. These feet are usually made of iron, but they may be formed of other materials. A fort of inclined plain is formed from the bottoms of the quarries or pits, up which it is forced, with great ease and facility, by the workmen, or small animals of the horse kind, after being filled with their forts of heavy materials. It is a very useful and convenient machine in this application, being met with in most of the slate quarries in the northern part of Lancashire, as well as in those of many other districts of the kingdom.

**Quarrying**, the business of directing and conducting the nature and management of making the different kinds of quarries, pits, and shafts, as well as of the different forts of work which are necessary to be undertaken, carried on, and performed, in the several different descriptions of them; such as those of separating, getting up, and preparing the various sorts of materials for use in the arts, or in other ways. It is a practice which requires considerable knowledge and experience, to be fully master of it in all its different bearings and intentions. See **Quarry**, and **Quarrying Slate and Stones**.

Almost every fort of quarrying-work requires a different kind of management, not only in the opening and making the quarries and pits in the grounds at first, but afterwards in the methods and practices of working them, and getting up the various sorts of materials from them, as well as in the manner of preparing, trimming, and arranging them, after they have been raised.

**Quarrying Slate and Stones**, the methods of preparing and fitting them for their different uses and applications at the quarries and pits where they have been raised.

The form of these articles, particularly those of the blue, green, and purple or blackish kinds, undergo several different forms of preparation in the quarrying, according to the purposes to which they are to be afterwards applied. They are separated and divided into very thin pieces or slates, where light, neat coverings are required, or in much demand; but for more strong and heavy coverings, in exposed situations, or other places, they are split into much thicker sheets, layers, or slates, and are, of course, more clumsy in their appearance.

Each fort in the furnaces of quarrying is wrought in a separate manner, and packed up by itself; the different forts having appropriate names, as has been already seen.

The white or brown slates are never divided and prepared in fo thin a way as the other kinds, but separated into much thicker flakes or lamins, in this intention. The blue, green, and purple or darkish forts, are, for the most part, found capable of being split into very thin lamins or sheets; but those of the white, or brownish free-lone kinds, can seldom be separated or divided in any very thin manner, as the layers of the large masses of the slates are of a much thicker nature, they consequently form heavy, strong, thick coverings, proper for buildings in exposed climates and situations, and of the more rough kinds, such as barns, stables, and other forts of out-houses.

In the different operations and processes of this fort of quarrying, slate knives, axes, bars, and wedges are chiefly made use of in the different intentions of splitting and cleaning the slates, they being separated into proper thickness, by the axe, bar, and wedge, and afterwards chipped into their proper forms and shapes by the knife. All the different inequalities which may appear upon any part of them, are likewise removed by this last fort of implement.

In the quarrying of the latter sorts of materials, or those of flones, the work is usually performed in such a manner as to suit the different uses for which they are intended. Where flags are to be formed, they are split or riven into suitable thicknesses, and squared to different sizes, so as to be adapted to different applications. These operations are executed in rather a rough way, as they are afterwards to be finished by the stone-mason. When for steps, they have the proper breadths and depths given to them in a fort of squaring manner, being left to be completed as they may be wanted for particular uses and applications. Gate-pulls are, for the most part, quarried fo as to have from about a foot to a foot and a half or more in the square. Rough-flones have the quarrying performed fo as to be formed into various proper-sized quarries or other forms, in a rough manner, being left in these slates to be afterwards hewn and hollowed out, in the intended parts, by the stone-masons.

Stones for building purposes are usually raised and quarried out roughly into something of the square shape, being left in that state for the builders, who afterwards fit them fo as to suit their own purposes and intentions.

In the quarrying of flones, the quarrymen commonly make use of large hammers, with cutting ends on one side, the other being formed in a plain manner; large, sharp, crowbars,
bars, and broad, sharp, iron wedges; by which means these matters are, from the continual practice of the men, split and torn into such forms as are wanted with great ease and facility. See QUARRY.

Quarrying Tools, the different sorts of implements which are employed or made use of in the different works of this kind, as in the raising and preparing the various sorts of materials of this nature. They are principally such as those which have been noticed already, and different descripions of picks, mattocks, and jammers, or boring implements, for the purpose of blasting the various kinds of stone, and other hard materials. These tools are individually described under their particular heads. See each of them.

Quayings, the small pieces which are broken or chipped off from the different sorts of materials which are found and wrought in quarries, while they are undergoing their different preparations for various uses. These fragments, where they are of the hard kind, such as those of the blue and lime-stone, as well as some other forts, are extremely well calculated for the purposes of forming and repairing roads, as they are nearly, if not quite, in a flake fit for immediate application in this way. Materials of these kinds ought, therefore, where they can be conveniently had, never to be neglected by those who have the care and management of roads, as they will save much expense and trouble, in a great number of instances. See Road.

Quart, q. d. fourth, in Myers. See QUARTER.

Quart is particularly used for a diminutive measure, containing one-fourth, or quarter, of some other measure; which fee.

The English quart is a fourth of a gallon, or two pints; the Roman quart, or quartarius, was the fourth part of their congius.

The committee appointed for examining the standards of weights and measures, and ascertaining those that shall be used in this kingdom, delivered it as their opinion, in their report to the house of commons, A.D. 1814, that the gallon ought to contain 10 pounds of pure water, or 276.48 cubic inches; that the quart, or fourth part of the gallon, ought to contain 40 ounces of water, or 69.12 cubic inches; and that the pint, or half of the quart, ought to contain 20 ounces of water, or 34.56 cubic inches.

The French, from whom we borrow the word, besides their quart, or pot of two pints, have various other quarts, distinguished by the whole of which they are quarters; as quart de milles, and quart de heptaires. See MILE, and HEBBLE.

Quart of Butter, in Rural Economy, a name given to a lump which contains the quantity of three pounds; and which is a mode of selling it that is peculiar to some districts, it being carried in this flate to the markets.

Quart de Soupir, in Fr., Myers, is a reel equal to a demi-quarver. By a 4th part of a fourp is meant an equivalent to a double croche, or two quavers in French, and one crotchet in English. See Time-table, and Value of Notes.

Quart de Ton, Fr., a quarter of a ton, an interval introduced into the enharmonic genus by Arlotosus. We have neither ear nor harmonic calculations that can furnish us with the exact interval or ratio of a quarter-tone; and when we consider what nice geometric operations are necessary to settle it on the monochord, we are very apt to suspect that this true quarter-tone never has been nor ever will be produced exactly in tune either vocally or instrumentally. Musicians, however, call the difference between A and Bb, a quarter-tone, an interval which, though in nature, is annihilated by temperament.

This quarter-tone is pretended to be of two kinds; the enharmonic major, in the ratio of 576 to 625, which is the complement of two minor femitones to a tone major; and the enharmonic minor, in the ratio of 125 to 128, which is the complement of the same two minor femitones to the minor tone. Rouleau.

Quartan, in Medicine, an acute or intermittent fever, the paroxysms of which recur every third day, leaving two intervening days without fever. This is vulgarly called a third-day ague; but in medical language it is termed quartan, or fourth-day ague, because if we reckon the day on which the diseafes comes as one, then the second paroxysm is on the fourth day, which again becomes one in relation to the succeeding paroxysms. See FEVER, QUARTAN, and AGUE. See also TERTIAN.

Quartarius, a measure among the ancients, being the fourth part of a sextary, and nearly equal to a quarter of a pint of our wine-measure.

Quartaro, in Commerce, a liquid measure at Venice. The amphora, which is a wine-measure, contains 4 bigoncio; a bigoncio 4 quartari, 16teches, or 256lb. Pelo grofso; but a bigoncio of brandy is only 14 teches, or 56lb. Kelly's Un. Camb. It.

Quartation, in Metallurgy, the separation of silver from gold by means of aqua fortis or nitric acid; which is an operation that has something singular in it.

If silver and gold are mixed together into a mafs, and the gold is not less than one-third part of the mafs in weight, the best aqua fortis poured upon it is not at all capable of dissolving the silver; but if you add more silver to this mafs, by melting it again in the fire, with such a necessary addition of that metal alone as should bring the gold in the mafs to the proportion of less than one-third of the whole, and suffer it to cool, then aqua fortis poured on it will corrode the silver from it; this is also by so much the more strongly performed, as the quantity of gold is less than in the proportion of one-third of the whole mafs; but experience has taught us, that aqua fortis dissolves silver mixed with gold quickly enough when the gold constitutes but one, and the silver three parts of a mixed mafs of them; and in this case, if the solution is not too impetuously performed, the gold usually remains in such a proportion, in the same figure that the whole mafs had before the separation of the silver by this methodum; so that, in this case, there is no reason to apprehend the gold's being torn into minute particles, and disintegrated in fomice measure; though this can hardly be prevented when the silver exceeds the three-quarter proportion, in regard to the gold in the mafs. The artificers, therefore, always make it their study to observe very exactly this proportion of the gold being one-fourth part of the mixture; and thence it is that the operation itself has been called quartation.

In order to ascertain nearly the proportion of gold and silver in a mafs, the avelayers rub this mafs upon a touch-stone, so as to leave a mark upon it; and they then make marks upon the stone with some of these needles, called touch-needles, the colour of which they think comes nearest to that of the mafs; by comparing the marks of these needles with the mark of the mafs, they discover nearly the proportion of the gold and silver in the mafs. The mafs of gold and silver to be quartered ought previously to be granulated, by melting it in a crucible, and pouring it into a large vessel full of cold water, while at the same time a rapid circular motion is given to the water by quickly illicking it round with a flick or broom. The vessels generally used for this operation are called parting-glassses. The aqua fortis must be purified for this purpose, and should be four strong as to be capable of setting tellibly on silver when cold, but not so strong as to act violently. If fit be very strong, and the vessels well
well closed, a small quantity of the gold will be dissolved along with the silver, which is to be guarded against. Little heat ought to be applied at the beginning, the liquor being apt to swell and rise over the vessel; but when the acid is nearly saturated, the heat may be safely increased. When the solution cools, which may be known by the discontinuance of the effervescence, or emission of air-bubbles, the liquor is to be poured off. If any grains appear entire, more aqua fortis must be added, that all the silver may be dissolved. If the operation has been performed slowly, the remaining gold will have still the form of distinct masses, which are to receive solidity and colour by putting them into a tell under a muffle, and making them red-hot. If the operation has been performed hastily, the gold will have the appearance of a black mud or powder, which, after five or six washings with pure water, must be melted. The silver is usually recovered by precipitating it from the aqua fortis by means of copper vessels, into which the liquor is poured, or of plates of copper, which are thrown along with the liquor into glass vessels.

A considerable heat is required to accelerate this precipitation. Dr. Lewis observes, that when the aqua fortis has been perfectly saturated with silver, no precipitation is occasioned by plates of copper, till a drop or two of aqua fortis is added to the liquor, and then the precipitation begins, and continues as usual. The precipitated silver must be well washed in boiling water, and fused with some nitre, the ufe of which is to scorch any cuprous particles which may adhere to the silver.

Here we may add, that silver and gold may be parted from one another by the vitriolic acid, as effectually, though not fo commodiously, as by the nitrous. If the compound be reduced into grains or thin plates, and boiled in about twice its weight of oil of vitriol to dryness, the silver will be fo far corroded, as to be easily washed off by a little more of the acid: or if the mafs, after the corrosion, be melted in a crucible, the gold will separate and subside, the silver forming a scoria above it. Gold may be purified in the same manner from several other metallic bodies. M. Scheffer says, that this is the most direct way of separating tin from gold. Lewis's Com. Phil. Techn. 95. 149, &c. See Asaying, Depart, and Gold.

QUARTAUT, in Commerce, a wine measure in some parts of France: thus, at Blois, 3-74 quartauts are equal to 100 English gallons, and each of them contains 6183 cubic inches; in Burgundy, 3-68 quartauts are equal to 100 English gallons, and each contains 6275 cubic inches. Kelly's Un. Camb.

QUARE, Fr., Quarta, Ital., the 4th in music, and the third concord in point of perfection, according to the order in which concords are generated.

The 4th is a perfect concord: its ratio is 3 to 4. It is composed of three diatomic degrees, formed of four sounds; whence it has its name of fourth. Its interval is composed of two tones and a half: a tone major, a tone minor, and a major femitone.

The 4th may be altered two several ways: 1st, by diminishing its interval a femitone, and then it is called the diminished or false 4th; 2dly, by augmenting it a femitone, and then it is called a Tritonus, or Superlunary 4th. (See Tritonus.) But the diminished 4th is never used in harmony, and only touched now and then in melody as an appoggiatura, or note of refinement.

The 4th in thorough-bass is accompanied by the 5, and called by some the chord of the 11th.

Another chord is called the Superlunary 4th, or Tritonus, by the French; which is what we call the chord of the 5, or 5, in which the discord is in the base; but it is not the chord of the Tritonus, unless the 4th be sharp. See Chord, and Accompaniment.

The succession of two perfect 4ths is allowed in composition, even in similor manner, provided they are accompanied by the 6th; but there are page-lets that must not be abated, or pulped too far, as they are not authorized by the fundamental base. The Italians call a regular succession of chords of the 6th false bordons; for which see Fourth.

QUARTEL, in Commerce, a measure for train-oil at Hamburg: it contains 2 tonnes, or 64 flugten, and is reckoned at 2 centners, or 224 lbs. net weight. Kelly.

QUARTELOIS, Carleolus, or Cortice, furtouts, or upper garments, with coats of arms quartered on them, worn by the ancient knights in their military expeditions.

QUARTER, the fourth part of a whole, or integer divided into four equal portions.

In working of fractions, the quarter is expressed by 1/4; three quarters by 3/4.

Quarther, as a Weight, is a quarter part of the quintal, or hundred-weight.

The quarter is 28 pounds avoidupois.

Quarter is also a dry measure, containing of corn eight buhles stirked, or two sacks, being that by which corn is generally sold in the London market, and in large quantities in some districts of the country; and the quarter of coals is the fourth part of a chaldron, called a vat.

"Quarterum frumenti conflat ex octo buhliis." Fleta, lib. ii. This terms to have signified originally the fourth part of a ton in weight, or capacity. See Weight.

Quarter, in Allegany, the fourth part of the moon's period, or lunation, which is divided into four frages, or quarters; containing each from seven to eight days.

The first quarter is from the new moon to the quadrature; the second thence to the full moon, &c.

Quarter, in Heraldry, is sometimes used for a efechon, or coat of arms.

In this fene there are sixteen quarters required to prove nobility, in companies, or orders, where none but nobles are admitted.

The word quarters, required as a proof of nobility, is derived hence, that they used anciently to paint the coats of arms of the father, mother, grandfather, and grandmother, on the four corners of the tomb of the deceased.

In Flanders and Germany we frequently see tombs that have eight, sixteen, and even thirty-two quarters.

Quarter is also applied to the parts or members of the first division of a coat that is quartered, or divided into four quarters. See Quartering.

The king of Great Britain, in the first quarter, bears gules three lions passant or, &c. In the second quarter he bears azure three fleurs-de-lis, &c.

Quarter, France, is a quarter single, or alone; which is to oppose one-fourth part of the field.

This makes one of the honourable ordinaries of a coat. See Ordinary.

Quarter, in Latin, Quarterium Anni, is the fourth part of a year.

Hence the days on which those quarters slately come, are called quarter-days.

Quarter-days are the 25th of March, called Lady-day; the 24th of June, called Midsummer-day; the 26th of September, called Michaelmas-day, and the 25th of December, or Christmas-day. Quarter, Fr., in old counterpoint, was proceeding in dilucil by a succession of 4ths; which was called, in baron-
barous Latin, *diastellarum*; of which we have instances in the "Micrologus" of Guido.

**Quarter, in Navigation.** A quarter of a point, wind, or rhumb, is the fourth part of a cardinal point, wind, or rhumb; or of the distance between two cardinal points, winds, &c.

The quarter contains an arc of 11 degrees 15 minutes.

The quarter is what Wolfius, with regard to the other divisions, calls a secondary point of the second order.

**Quarter of a Ship** is that part of the ship's side which lies towards the stern, or which is comprehended between the aftmost end of the main chains and the sides of the stern, where it is terminated by the quarter-pieces. Although the lines by which the quarter and bow of a ship are determined, with respect to her length, are only imaginary, yet experience appears sufficiently to have ascertained their limits; so that if we were to divide the ship's sides into five equal portions, the names of each space would be readily enough expressed. Thus the first, from the stern, would be the quarter; the second, abaft the midships; the third, the midships; the fourth, before the midships; and the fifth, the bow. Falconer.

**Quarter, On the, in Sea Language,** may be defined as an arc of the horizon, contained between the line prolonged from the ship's stern and any distant object, as land, ships, &c. Thus if the ship's keel lies on an eait and well line, the stern being wellward, any distant object, perceived in the north-west or south-west, is said to be on the larboard or starboard quarter.

**Quarter is also used for a canton, or division of a city; containing of several ranges of buildings, &c. separated from some other quarter by a river, a great street, or by some other boundary.**

Thus are the twenty quarters of the city of Paris. Ancient Rome was divided several times, under its several augmentations, into quarters, which were called regins, as may be observed in the topographies of Aurelius Victor, Onuphrius Panvinius, Marllian, Pyro Ligorio, Boffard, and other antiquaries.

In many cities there are comminaries of the quarter appointed to look to the policy of them. The Prior of the Caporions accounts himself the chief and colonel of the fourteen reges, or quarters, of Rome. Mufcareat, p. 134.

**Quarters, Franchise of.** See Franchise.

**Quarter, in War,** the place allotted to certain forces to live, lodge, and encamp upon, during a siege, or the like. See Camp.

The general's quarter, called the head-quarters of an army, is that where the general lodges and encamps in person. They used to make lines of communication, to join the several quarters together.

**Quarters at a Siege,** are the encampments on the principal passes about a place; serving to float the avenues, and to prevent relief and convoys.

**Quarter is also used for any lodgment made in the field, or campagna, out of a siege.** Thus they say, the general has extended his quarters a good way; the enemy coming by, made him contract his quarters.

**Quarters, Intrenched,** denote a place fortified with a ditch and parapet, to secure a body of troops.

**Quarters, Winter,** the place allotted to pafs the winter season in. Wherein these differ from garrisons, see Garrison.

**Winter-quarters, when cold or moist, are productive of inflammatory disorders, particularly hard coughs, with inflammations of the pleura or lungs.** See Barracks.

**Quarters, Winter,** are also used for the time the troops continue in this lodgment; and for the advantage the captains make of it.

In Spain they have also summer quarters.

**Quarter of Assembly,** is the place of rendezvous, where the troops are to meet and draw up, to march in a body.

**Quarters of Rest, or, Rest, quarter, quarter of a ship's deck, where the officers, quartered on board the same, are to remain.**

**Quarter of punishment, in which the crews of ships, or the officers of garrisons, are sometimes de- nied the use of their arms,** when condemned to be disembarked; or, in other cases, made prisoners of war. See Punishment.

**Quarter, the place in which any soldiers, or officers, are quartered,** is called quartering. See Quartering.

**Quarter of settlement, quarter of a ship's quarter, the guard of a ship.**

**Quarter, a place, or a day, in which any soldiers are quartered.**

**Quarter of punishment,** in which the officers, or soldiers, are sometimes deprived of their arms, when condemned to be disembarked; or, in other cases, made prisoners of war. See Punishment.

**Quartering, a place, or a day, in which any soldiers, or officers, are quartered, or in which they are quartered, or in which they are quartered.**

**Quarter of a ship, quarter of a ship, the guard of a ship.**

**Quarter, the place in which any soldiers, or officers, are quartered.**

**Quarter, a day in which any soldiers, or officers, are quartered.**

**Quarter of punishment,** in which the officers, or soldiers, are sometimes deprived of their arms, when condemned to be disembarked; or, in other cases, made prisoners of war. See Punishment.**

**Quarter, a day in which any soldiers, or officers, are quartered.**

**Quarter of settlement, quarter of a ship's quarter, the guard of a ship.**

**Quarter of punishment,** in which the officers, or soldiers, are sometimes deprived of their arms, when condemned to be disembarked; or, in other cases, made prisoners of war. See Punishment.**

**Quarter, the place in which any soldiers, or officers, are quartered.**

**Quarter, a day in which any soldiers, or officers, are quartered.**

**Quarter of settlement, quarter of a ship's quarter, the guard of a ship.**

**Quarter of punishment,** in which the officers, or soldiers, are sometimes deprived of their arms, when condemned to be disembarked; or, in other cases, made prisoners of war. See Punishment.
and, besides, courage supplies the want of fortifications. It is urged farther, that by threatening a commander with death, you may threaten the bloody fiere, spare your troops, and gain a valuable opportunity. The answer is, says Vsett, that a brave man will despise your menace, or, provoked at such ignominious ufage, will fell his life at a dear rate, make you pay for your injustice, and bury himself under the ruins of his fort. Besides, the menace of an unjust punishment is unjust in itself; it is an insult and an injury. But to execute it, would be barbarous and horrible; and if it is not to take effect, it must be allowed to be vain and ridiculous. Nevertheless, jud and lawful means may be used for inducing a governor not obstinately to reduce himself to the last extremity; and this is at present done by all wise and humane generals. A governor is summoned to surrender, and in the progress of the siege an honourable and advantageous capitulation is offered him, with an intimation that if he stays too long, he will be admitted only to surrender as a prisoner of war, and at diference: if he perfides, and is at length forced to surrender at diference, all the severity of the law of war may be used, both against him and his troops. But this right never extends so far as to deprive an enemy of life, who lays down his arms, unless he has been guilty of some proportionate crime towards the conqueror. See CAPITULATION, PRISONERS OF WAR, and REPRISALS.

QUARTERS, in Building, those flight, upright pieces of timber, placed between the pinnacles and pails; used to lash upon. They are of two kinds, single and double. The single quarters are fawn to two inches thick, and four inches broad; the double are four inches square.

Quarters in a clock, are little bells, which found the quarters of an hour.

QUARTERS, in Sea Languages, the several stations of a ship's crew in the time of action. See QUARTERING THE MEN.

QUARTER, in the Measure, to work from quarter to quarter, is to ride a horse three times upon the first of the four lines of a square; then changing your hand, to ride him three times upon the second; so to the third and fourth, always changing hands and observing the same order.

Quarters of a Saddle, the parts or pieces of leather, or stuff, which are made fast to the lower part of the sides, and which hang down below the faddle.

Quarters of a Horse, and other Animals, the four principal parts of the animals; the fore-quarters consist of the shoulders and the fore-legs; the hind-quarters, of the hips and the hind legs.

In the horse, the fore-quarters or shoulders should always fall in a neat manner backwards, where they join with the breast, and the hind-quarters be fitly long and well shaped towards the rump. Something of a similarity of shape should likewise prevail in the quarters of neat cattle, sheep, and swine, but they should be much more fleshy downwards as they approach the thigh and leg parts. See LIVESTOCK, HORSE, SHEEP, and SWINE.

Quarters of the Foot, in horses, are the sides of the coffin, comprehended between the toe and the heel on both sides; the inner quarters are those opposite to one another, facing from one foot to the other; the outer are always weaker than the outsize quarters, which lie on the external sides of the coffin. A horse is said to have a false quarter, when the hoof has a kind of cleft occasioned by the cutting the quarter and getting a new one, for then the horn becomes uneven, and also softer than the rest of the hoof; and the foot should be shod with some nicety. But if the cleft be considerable, and take up a fourth of the hoof, the horse is worth little afterwards for any purpose.

QUARTER-GALLOP, among horses, is when for any disease in the coffin-bone or joint, one of the quarters of the hoof is call off, and when thus call'd, the reproduction of a new hoof or part takes place. It is a common occurrence among some horses.

QUARTER-EVIL, among domestic animals of the neat cattle kinds, is an affection which sometimes takes place in the glands of the udders, and sometimes in different parts of the feet.

Quarters, in Gardening, the large divisions of garden grounds, or those parts of them which are situated between the different walks, at a distance from the walls, narrow portions on the sieds usually termed borders, and which form or constitute the principal spaces or compartments for the cultivation and growth of the various sorts of the most useful culinary vegetables which are raised in large quantities; such as peas, beans, cabbages, cauliflowers, broccoli, early potatoes, and many others.

It is necessary to have the quarters of garden grounds formed and laid out in such a manner as to favour the growth of early and late crops of the several different sorts, as much as possible: those for the former having a southern, or south-western exposure, and those for the latter, an eastern, or north-eastern aspect. By these means, early crops are, in some measure, rendered more forward and fine, and those of the more late kinds, in some degree, prevented from being injured or burnt up and destroyed by too full an exposure to the heat of the sun.

It is usual during the winter season to have the large quarters of garden grounds laid up in high ridges, in order to be exposed to the influence and effects of frost, by which the earth may be rendered more light and mellow, and be in a more fit state for sowing or planting in the spring months, on throwing them down and rendering them level for the purpose.

The large quarters of gardens should likewise be kept as free and open as possible, not being inclosed and choked up, as is too frequently the case by planting fruit-trees and shrubs on their sides, either in the manner of espaliers or otherwise, as by such means the growths of the plants are much promoted, and they are prevented from being drawn up in a weak manner. See GARDEN.

All forms of garden grounds are found, except that of the square, to demange the regularity of the quarters, and, of course, to render them highly troublesome in digging and cropping. Where they are very large they may be subdivided into suitable fizes, as one hundred feet in breadth, &c.; but their length does not signify, as it may be varied in different ways, as by rows of trees, bushes, or which, in many cases, are preferable, by broad walks and the modes of cropping.

Quarters of a Garden, the several divisions into which it is formed for the purpose of cultivating the different kinds of vegetables, fruits, &c. Thus, there are parts or quarters defined to the growth of kitchen vegetables, fruit, and other trees, forcing, &c.

Quarters of a Field, or Farm, in Agriculture, are the particular parts of them, which are used, set apart, or intended for any sort of crops, or peculiar modes of cultivation and management. Farmers are frequently in the practice of dividing their lands or farms into different quarters, or parts, according to the different sorts of husbandry which they are proper for, and the manner and proceeding in which the various kinds of crops are to be grown upon them, and the same is often the case with large fields, four, five, six, and more divisions or quarters, being common in such

influres.
inflances. This plan of proceeding is supposed to give ease, facility, and dispatch, to the work which is afterwards carried on, as well as to have several other advantages and conveniences. See Farm.

Quarter-Bill, in Sea Language, a roll or list, containing the different stations, to which all the officers and crew of the ship are quartered, in the time of battle, and the names of all the persons appointed to those stations.

Quarter-Ball, a bullet quartered into four, or eight parts.

Quarter-Chord, in Mining, seven yards and a quarter, which the miner hath crofs-ways of his vein on either side, for liberty to lay his earth, flones, and rubbish on, and to wash and drefs up his ore.

Quarters, Close, in a Ship. See Close-Quarters.

Quarter-Cloths, are long pieces of painted canvas extended on the outside of the quarter-netting from the upper part of the gallery to the gang-way. They are generally decorated with martial instruments, or allegorical figures.

Quarter-Day. See Quarter.

Quarter-Deck of a ship, is that aloft the leesage, reaching to the round-house; or that deck in ships of war which extends from the main-mast to the stern, next above the upper-deck.

Quarter, Fat, in a Ship, denotes the fame with broad. Thus, if the truffling in, or tack of a ship's quarter under water be deep, they say, the hath a fat quarter.

Quarter-Galler, a sort of small balcony, with or without balustrades, on the quarter of a ship; which generally communicates with the gallery on the stern, by means of a door palling from one to the other.

Quarter-Guard. See Guard.

Quarter-Gunner, is an inferior officer under the direction of the gunner of a ship of war, whom he is to assist in every branch of his duty; as keeping the guns and their carriages in proper order, and duly furnished with whatever is necesary; filling the powder into cartridges; sealing the guns, and keeping them always in a condition ready for service. The number of quarter-gunners in any ship is always in proportion to the number of her artillery; one quarter-gunner being allowed to every four cannon.

Quarter-Netting, is a sort of net-work, extended along the rails on the upper part of a ship's quarter. In a ship of war these are always double, being supported by iron cranes, placed at proper distances. The interval is sometimes filled with cork or old fells, but chiefly with the hammocks of the sailors, so as to form a parapet to prevent the execution of the enemy's small arms in an engagement.

Quarter-Pieces, substantial pieces of timber, mostly of fir, that form the outboundary of the stern, and connect the quarter-gallery to the stern and toftaid.

Quarter-Point of the Compass. See Point.

Quarter-Rails, in a Ship, are narrow-moulded planks, generally of fir, reaching from the top of the stern to the gang-way. They are supported by flanches, and serve as a fence to the quarter-deck, to prevent the men from tumbling into the sea by the rolling of the ship, particularly in small vessels.

Quarter-Round, in Architecture, is a term used by the workmen for any projecting moulding in general, whose con- tour is a perfect quadrant, or quarter of a circle, or which approaches near that figure. The architects usually call it ovolo; and Vitruvius, the echinus.

Quarter-Staff, a long staff, or pole, borne by foresters, park-keepers, &c. as a badge of their office; and occasionally used as a weapon.

Quarter-Wheeling, or Quarter of Conveyon, in the Military Art, is the motion by which the front of a body of men is turned round to where the flank was; this making the quarter of a circle.

If it be done to the right, the man in the right-hand angle keeps his ground, and faces about, while the reit wheel; if to the left, the left-hand man keeps his place. &c.

Quarter-Wind, at Sea, is a lateral, or side-wind, or a wind which does not blow in stern, but a little aside of it.

Properly, the quarter-wind is that which comes in afloat the main-mast throunds, even with the quarter of the ship.

The quarter-wind is the belt of all winds, as bearing into all the sides; whereas a wind blowing full in stern, is kept off by the fails of the mizen.

QUARTEIRA, in Commerces, a corn-measure in Spain, containing 12 cortanes; the falma contains 4 quartas, or 48 cortanes; the carga, 2½ quartas, or 50 cortanes; 78½ quartas correspond to 100 Castilian fauces; and 100 quartas Catalan to 128 Castilian faues; 39 quartas Catalan contain 10 English quarters. The carga of wine and brandy is divided into 16 cortanes, 32 quartas, or 128 quartillos.

At Barcelona 39.08 quartas are equal to 10 English quarters, and a single quartera contains 4401 cubic inches. Kelly's Un. Cambilt.

QUARTEERED, Counter. See Counter-QUARTEERED.

QUARTERIDGE, money paid quarterly, or by the quarter.

QUARTERING of Soldiers, in Military Language, seems to have antedated very little from that now in use, except that they were indiscriminately quartered upon all householders, as was practised in England to late as in the rebellion of the year 1745. Rapin says, that William the Conqueror quartered almost all his troops upon the monasteries, and obliged the monks to furnish them with necessaries; by which means he maintained his army without any charge, and had spies in all their religious houses, who watched the actions of the monks; these houses were long after charged with finding carts and horses for the carrying the baggage of the army; and there are still extant many of the original returns from different monasteries, stating the number of each they were able to furnish for that purpose. About the time of Henry VII, we meet with a regulation that bears some reference to quarters; this is a coat and conduct-money; the first was a species of clothing, probably for recruits; the money for which was advanced by the county in which they were raised; —conduct-money was an allowance for subsistence, to and from the army, according to the number of days which the soldiers had to march; a day's march being estimated sometimes at 12 and sometmes at 15 miles. Both the coat and conduct-money were occasionally advanced by the different counties in which the troops were quartered, under the promise of being repaid by government. Towards the latter end of the reign of James II, and even after the accession of William III, soldiers used to oblige the inhabitants of the towns in which they were quartered, not only to furnish them with diet and lodging, but also to advance them their daily subistence. After the revolution, by the mutiny-acts, passed the 23d day of December, in the year 1689, other laws and regulations respecting quarters were enacted.

By the petition of right in the third of Charles II, it is enacted and declared, that the people of the land are not by the laws to beburse with the foujourning
of soldiers against their wills; it is also enacted by the 31 Car. II. c. 1. that no officer, military or civil, nor any other person whatsoever, shall presume to place, quarter, or billet any soldier on any subject or inhabitant of this realm, of any degree, quality, or profession whatsoever, without his consent; and every such subject or inhabitant may refuse to fojourn or quarter any officer, notwithstanding any command, order, warrant, or billeting whatever. The present mode of quartering our troops is settled by the Mutiny Act, renewed annually, with little or no alteration. Accordingly by the Mutiny Act, § 49 Geo. III. c. 12. s. 41, the constables and other chief officers and magistrates of cities, towns, villages, and other places, and in their default or absence, any one justice inhabiting in or near such place, and no other, shall and may, during the continuance of this act, quarter and billet officers and soldiers in inns, livery stables, alehouses, victualling houses, and the houses of sellers of wine by retail to be drank in their own houses or places thereunto belonging, (other than porn's canteens held under the authority of the commissioners for the affairs of barracks, and other than persons who keep taverns only, being free of the victuarrs company in London,) and all houses of persons selling brandy, strong waters, cider, or mead, by retail to be drank in houses, (other than the houses of distillers who keep places of distilling brandy and strong waters, and of shopkeepers whose principal dealings shall be more in other goods than in brandy and strong waters, and who do not permit tipping in their houses,) and no other, and in no private houses whatsoever; nor shall any more billets be ordered than there are effective soldiers; which billets when made out shall be delivered to the commanding officer present; and if any constable, or such like officer or magistrate as aforesaid, shall presume to billet any such officer or soldier in any private house without the consent of the owner or occupier, such owner or occupier shall have his remedy at law against such magistrate or officer, for damages; and if any military officer shall take upon him to quarter soldiers otherwise than by this act, or shall offer any menace or compulsion to any mayor, or other civil officer before-mentioned, tending to discourage any of them from doing their duty, he shall on conviction before any two justices by the oath of two witnesses be ipso facto caahered and disabled to hold any military employment; provided the conviction be affirmed at the next quarter sessions, and a certificate thereof be transmitted to the judge advocate, who shall certify the same to the next court martial. And if any person shall be aggrieved by having more soldiers billeted on him in proportion to his neighbours, on complaint thereof to one justice of the division, &c. where quartered, or if the person so billeting them be a justice, then on complaint to two justices they may relieve him.

Note.—The clause above recited, relating to shopkeepers, might as well be now omitted out of the act; for that by the 17 Geo. II. c. 17, no shopkeepers, as such, are allowed to retail any spirituous liquors, but only those who keep taverns, victualling houses, inns, coffee-houses, or ale-houses.

By s. 43. No justice, having any military command, shall be concerned in quartering soldiers under his immediate command; but all things done by him therein shall be void.

By s. 50. of this act, an officer taking money for executing the quartering, shall be cashiered.

By s. 51. If any high constable or other officer or any person whatsoever shall neglect to quarter any officers or soldiers, provided sufficient notice be given him before their arrival, or if he receive or agree for any reward in order to excuse any per son from receiving such officer or soldier, or if any victualler, &c. having any officer, &c. billeted upon him, refuse to receive him, or refuse to furnish him as herein provided by this act, and shall be thereupon convicted by one justice of the county, &c. where such offence was committed, on confession of the oath of one witness, he shall forfeit not more than 5l. nor less than 48s. to be levied by diftres; which sum shall be applied in his to satisfy such felder for the expense thereby occasioned to him, and the remainder to the overseers of the poor of the parish where the offence was committed.

By s. 56. If any officer, military or civil, shall quarter any of the wives, children, or servants of officer or soldier, in any house, against the consent of the owner; if he be an officer, he shall on proof made thereof to the commander in chief of the army or judge advocate, be ipso facto cashiered; and if a civil officer, he shall forfeit to the party grieved 20s. on proof thereof to the next justice by diftres.

By s. 53. Officers and soldiers, billeted as aforesaid, shall be received and furnished with diet and small beer, paying for the same as hereafter mentioned, out of their subsistence-money.

By s. 54. If any person shall choose rather to furnish non-commisioned officers or private men, with candles, vinegar, and rags, gratas, and allow them the use of fire and the necessary utensils for dressing and eating their meat, and shall give notice thereof to the commanding officer, and shall furnish the same accordingly; in such case they shall provide their own victuals and small beer, and the officer who receives their pay shall pay the sums after mentioned, out of the subsistence-money for diet and small beer to them, and not to the persons on whom they are quartered.

By s. 55. Every officer receiving the pay or subsistence-money, either for a regiment, or particular troops and companies, or otherwise, shall immediately, upon each receipt of each sum, give public notice thereof to all on whom officers or soldiers are quartered; and shall also appoint such per sons to repair to their quarters, at such times as they shall appoint, for the payment of the said pay or subsistence-money to the officers or soldiers, which shall be within four days at the farthest after the receipt of the same, as aforesaid; and such persons shall then and there acquaint such officer with the accounts or debts between them and the officers and soldiers quartered; which accounts the said officer is to accept of, and immediately pay the same, before any part of the pay or subsistence be distributed: provided the said accounts exceed not, for a commission officer of horse being under the degree of a captain, for such officer's diet and small beer, per diem, 2s. 4d.; nor for one commission officer of dragoons, being under the degree of a captain, for such officer's diet and small beer, per diem, 2s. 4d.; nor for one commission officer of foot, under the degree of a captain, for such officer's diet and small beer, per diem, 1s. 4d.; nor for each horse quartered under this act, for hay and straw, per diem, 6d.; or for one light horsem. man's diet and small beer, per diem, 7s. 6d.; and hay and straw for his horse, per diem, 6d.; or for one dragoon's diet and small beer, per diem, 7s. 6d.; and hay and straw for his horse, per diem, 6d.; or for one foot officer's diet and small beer, per diem, 5s.; and if such officer shall not give notice and shall not immediately upon producing such account stated above, pay the same; upon complaint on oath by two witnesses, at the next quarter sessions for the county or city where such quarters were, the paymaster of the guards, garrisons, and marines, are authorized (upon certificate of the said justices before whom such oath was made, of the sum due upon such accounts and the per-
fons to whom the fame is owing) to pay the said sums out of the arrears due to the said officer, upon pain of such paymaster forfeiting his place, and being incapacitated from holding it again. The act then states what course is to be pursued if there be no arrears due, or no subsistence-money remitted, and is directory of the course to be pursued by the paymaster.

By f. 49. The commanding officer may exchange any men or horses quartered in any place with another man or horse quartered in the same place, provided the number of men and horses do not exceed the number at that time billeted on such house.

By f. 47. And where any horse or dragoon shall be quartered upon any person who hath no stables, upon his complaint to two justices of the division, &c. and his making such allowance as such justices shall think reasonable, they may order the men and their horses, or the horses only, as the case may be, to be removed and quartered upon some other person who hath stables, and may order and settle a proper allowance to be made by the person having no Stables, in lieu of his quartering such horse or dragoons, and order payment thereof to the person to whom the removal is made, for or to be applied for the furnishing of quarters for such men and their horses.

By f. 49 Geo. III. c. 37. It is enacted that every non-commissioned officer and private soldier who shall be furnished with diet and small beer by the persons on whom they are quartered, shall pay for the same 1s. 4d. per day, in like manner as by the first act is enacted as to the 7d. per day.

By f. 2. Where the inholder, &c. furnishes certain articles in lieu of diet and small beer, as in the former act mentioned, he shall have one halfpenny per day for each non-commissioned officer, &c.

By f. 3. 1s. 3d. per day is to be paid for each horse, instead of 6d. per day.

By f. 4. The provisions in the former act relating to the dieting on a march or recruiting are repealed.

By f. 5. All non-commissioned officers and soldiers shall receive their diet and small beer at the above rates while on the march and on the day of arrival at the place of their final destination, and on the two subsequent days, unless either of the two be a market day for the place where billeted, or within two miles thereof; in which case the innkeeper, &c. shall discontinue on and from such market-day the diet and small beer, and furnish in lieu thereof the articles in the said former act specified, and at the rate in this act prescribed.

By f. 6. If any person liable to have soldiers quartered on him shall pay any sum to any non-commissioned officer or soldier on the march in lieu of the diet and small beer, he may be proceeded against and fined as if he had refused to furnish according to the former act the things to be furnished to non-commissioned officers and soldiers so quartered as aforesaid.

By f. 7. The provisions of f. 5. are extended to halting on a march.

By f. 8. But if the halt be for longer than one day, and the day after the arrival be market-day as aforesaid, there is to be no discontinuance of diet and small beer.

By f. 9. Non-commissioned officers and private men employed in recruiting, and the recruits by them raised, shall, while on the march, and for two days after the day of their arrival at any recruiting station, be entitled to the same benefits as before provided for troops on the march; but no recruit enlisted after the two days subsequent to the arrival of the party at their recruiting station, shall be entitled to be supplied with diet and small beer at the rate herein-before preferred, except at the option of the party where quartered.

Provided that in case any recruiting party, with the recruits by them raised, shall remove from their station, and after a time shall return to the same place, they and the recruits shall not be again entitled to the diet and small beer for two days, unless the time of absence exceed 20 days. This act to continue to 25th March 1810.

By f. 52. Any justice within his county, &c. may command any constable or other officer who shall billet any soldiers, to give an account in writing to him of the number of officers and soldiers billeted by them, and the names of the persons on whom quartered, and an account of the place where they dwell, and of their signs, if any. See Military Law, and Soldiers.

But by the 50 G. III. c. 26. f. 1. it is enacted, that after the 25th of June 1810, every non-commissioned officer and private soldier who shall be furnished with diet and small beer within the parts of the united kingdom mentioned in the 50 G. III. c. 28. by the inholders or other persons on whom such non-commissioned officers or private soldiers shall be quartered and billeted by virtue of the said act, shall pay and allow for the same, the sum of eight-pence per diem instead of one shilling and four-pence per diem, as in the said act specified; and that for such allowance of eight-pence, the innkeeper or other person shall furnish one meal; videlicet, a hot dinner if required in each day to each non-commissioned officer, trumpeter, drummer, and private soldier quartered and billeted on him, to consist of such quantities of diet and small beer as shall be specified and fixed in and by any regulations made or to be made from time to time by his majesty in that behalf, but not to exceed one pound and a quarter of meat previous to being dressed, one pound of bread, one pound of potatoes or other vegetables previous to being cooked, and two pints of small beer, and vinegar, salt, and pepper.

And by f. 2. of the same act, the mutiny act, and the said 50 G. III. c. 28. shall be applied for the enforcing such regulations as to the diet of soldiers and the payment of and accounting for the allowances for the same.

Quarterming of Treasons, in Law. See Treason.

Quarterming, in the Sea Language. When a ship under sail goes at large, neither by a wind nor before a wind, but, as it were, betwixt both, she is said to go quarterming.

The term is also used when a ship fails with quarter-winds.

Quarterming the Men, the disposing of the ship's company at the time of an engagement in such a manner, that each may readily know where his station is, and what he is to do; as, some to the masts, for the management of the sails; some to assist the gunners to traverse the ordnance; some for firing the enemy with small shot; some to fill powder in the powder-room; others to carry it from thence to the gunners in cartridges, &c.

The number of men appointed to manage the artillery is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are in general as follow, when the ship is well manned, so as to fight both sides at once occasionally:

<table>

The lieutenants are usually stationed to command the different batteries, and direct their efforts against the enemy. The master superintends the movements of the ship, and whatever relates to the fails. The boatwain and a sufficient number of men are stationed to repair the damaged rigging; and the gunner and carpenter whatever may be found necessary, according to their respective offices. The marines are generally quartered on the poop and forecastle, or gangways, under the direction of their officers; although, on some occasions, they affix at the great guns, particularly in distant cannonading. Falconer. See Engagement.

Quartering, in Gunnery, is when a piece of ordnance is so traversed, that it will shoot on the same line, or on the same point of the compass, as the ship's quarter bears.

Quartering, in Heraldry, the act of dividing a coat into four or more quarters, or quarterings, by parting, coupins, & c. by perpendicular and horizontal lines, &c. See Quarter and Quarterly.

The king of Great Britain quarters with Great Britain, France, Ireland, Brunswick, &c.

Colombiere reckons twelve sorts of quartering; but other authors give us more—viz. party per pale, dividing the escutcheons from top to bottom. See Pale.—Party per cros, dividing it from side to side. See Cross.—Party of six pieces, when the escutcheon is divided into six parts, or quarters. Party of ten; of twelve; of sixteen; of twenty; and of thirty-two; when there are so many partitions respectively.

Others give the divisions in another manner: as—Party per crosse—per pale—per chief—per pale irèclaye—per bend dexter—per bend f-letter—per chevron—barry bendy of eighty pieces—paleways of six pieces—barry of fix pieces—barry of eight pieces—bendy of fix pieces—checky—fully, or lozengy—pale bendy, or bendy lozengy—barry bendy lozengy, or bendy lozengy—grynoy—barry lozengy counterchanged—waved of fix pieces—barry nebule of six pieces—party per falkier—and party per pale in point. See farther under their respective articles.

Counter-quartering a coat, is when the quarters are quartered over again, or subdivided each into four. See Counter-quartered.

There are counter-quartered coats which have twenty or twenty-five quarters.

Quartering is also applied to the partitions or compartments themselves, that is, the several coats borne on an escutcheon, or the several divisions made in it, when the arms of several families are to be placed on the same shield, on account of intermarriages, or the like.

Colombiere observes, that thirty-two is the greatest number used in France; but that the English and Germans sometimes extend to forty: as a testimony of the truth of which, he says he saw the escutcheon of the earl of Leiceter, ambassadour extraordinary in France in the year 1639, divided into the number of forty; and he affirms, do go on to sixty-four several coats.

But a multitude of quarters make a confusion; and, accordingly, all the writers of armory exclaim against it as an abuse. The first instance of quartering, of which we have any account, is said to be in the arms of Renatus, king of Sicily, &c. in the year 1435, who quartered the arms of Sicily, Arragon, Jerusalem, &c.

William Wickly observes, that such quarterings are much more proper for a pedegree, to be locked up in a chest, and occasionally produced as an evidence for the clearing or ascertaining of alliances of families, and titles to lands, &c. than to be borne as a cognizance.

In blazoning, when the quartering is performed per crosse, the two quarters a-top are numbered the first and second; and those at the bottom the third and fourth; beginning to tell on the right side. When the quartering is by a falkier, &c., he points at the first and second quarters, the right side the third, the left the fourth.

Quartering is sometimes also used for the distinguishing of younger brothers from elder. See Difference.

Quarterization, Quartering, part of the punishment of a traitor, by dividing his body into four quarters.

"Wallingham, in Ric. II. Audition et confellium tur- purpura fecleri tractationi, suspendio, decollationis, exenterationi, et quarterizationi adjudicavit."

Quarterly, in Heraldry, a person is said to be quartered, when he bears arms quartered.

The king of Great Britain bears quarterly of four; in the first quarter gules, &c. Great Britain; in the second, azure, &c. Ireland, &c.

Quarter-Master, an officer in the army, whose business it is to look after the quarters of the foldiers; their clothing, bread, ammunition, firing, &c. Every regiment of foot and artillery has a quarter-master, and every troop of horse one, who are only warrant-officers, except in the blues. Whereof there are several kinds; viz. the

Quarter-Master General, whose business is to provide good quarters for the whole army.

Quarter-Master of Foot, he who is to provide quarters for a regiment of foot.

Quarter-Master of Horse, he who is to provide quarters for a troop of horse.

Quarter-Master, in a Ship, is an inferior officer, appointed by the master of a ship of war to assist the mates in their several duties; as showing the ballast and provisions in the hold, coiling the cables on their platforms, overlooking the clearance of the ship, and keeping the time by the watch-glasses.

Quartern, Quarteron, a diminutive of quart, signifying a quarter of a pint; as a quart does a quarter of a gallon.

Quarrier, in Commerce, a liquid measure in Germany, which, according to a regulation of 1713, made in Hanover, must hold 2 lbs. of spring water, and the contents of which are 49 French, or 59 English cubic inches. A fuder of wine contains 4 exchon, 6 ahms, or 15 cimers; an ahm, 4 ankers, 40 flubgens, 80 kannes, 160 quarters, or 320 noffles. Hence 36 flubgens, or 144 quarters, = 37 English wine gallons. A fuis of beer at Lubec contains 42 flubgens, or 168 quarters. Kelly's Un. Cambill.

Quartile, an aspect of the planets when they are three signs, or 90 degrees distant from each other.
The quartile aspect is marked thus ☐. See Aspect.

**QUARTILLO**, in *Commerce*, a liquid measure in Spain. At Barcelona, 128 quartillos are equal to 32 quarts. (See QUARTERA.) A moyo of wine contains 15 arrobas; an arroba 8 arzambas, or 2 quarts. The arroba of wine contains 34 lb. of water (Castilian weight), and measures 13.74 Spanish, or 96 English cubic inches; hence four such arrobas are equal to 17 English wine gallons. The arroba of oil measures 966 Spanish, or 77.1 English cubic inches; so that three such arrobas correspond to 10 English gallons; this arroba is divided into 4 quartillos, or 100 quarterones, or palmillas. A Spanish bottle contains 50 arrobas of wine, or 33/4 of oil; a pipe is 27 arrobas of wine, or 34 1/4 of oil; thus the bottle is 127 1/2 English gallons, and the pipe = 114 3/8. Kelly. See Tab. XXXII. of Measures.

**QUARTO**, or qd., a book whereof four leaves, or eight pages, make a sheet.

**QUARTO**, in *Commerce*, a money of account in Spain. See Real.

**Quarto de peq.**, in Law, denotes the fourth day inclusive beyond the return of a writ, in which those who are summoned are allowed to make their appearance. See Extract of day of term.

**QUARTO-DECIMANS, QUARTO-DECIMANI**, in Ecclesiastical History, an ancient sect in the church, who maintained, that Easter was always to be celebrated, conformably to the custom of the Jews, on the fourteenth day of the moon in the month of March, whenever that day fell out.

And hence their name Quarto-decimani, q. d. Forty-teethers.

The Atheists were mightily attached to this opinion, pretending that it was built on the authority of St. John, who was their apologist; and pope Victor could never bring them to obedience in this article, though he was upon the point of excommunicking them: but it is more probable he contended himself with menaces. See Easter.

**QUARTUM par contingens**, in Anatomy, a name given by Spigelus and some others to the muscle called by Albinius and Riolanus orbicularis oris; and by Cowper and some others, contractor labiorum.

**QUARTUS hyoidis maxillarum**, a name given by Vefalius, Fabricius, and many other anatomists, to a muscle now generally called the coracohyoideus.

**Quartus oculum movens**, a name given by Vefalius to one of the muscles of the eye, called by some rectus inferior, and by others humilis.

It is the depressor oculi of Albinus, being one of the quartus recticuli oculi of that author.

**QUARTZ**, in *Mineralogy*. No substance in the mineral kingdom is more abundantly distributed than quartz. Grains of quartz generally compose a considerable part of the sands on the sea-shore, and of the sand-stones of the secondary era. Rolled pieces of quartz, or pebbles and boulders, are widely scattered over alluvial districts. Quartz is disseminated through granite, gneifs, mica-flake, and other compound rocks which constitute the loftiest mountains on the globe; it also forms veins of vast extent intersecting these mountains, and sometimes entire simple rocks are composed of this mineral. Quartz has a considerable degree of hardness, always striking fire with flint, and the fragments have sufficient solidity to resist the shock. Powdered quartz feels hard, and, when rubbed on polished steel, or on glass, scratches the surface. Quartz is infusible by the common blowpipe. These two qualities, hardness and infusibility, are the essential characters of all the varieties of quartz, whatever forms or colours they may present, whether mafive or crystallized.

Quartz has most commonly a conchoidal fracture, but sometimes the fracture is undulated, foliated, or splintery. The luster is vitreous. Quartz has various degrees of transparency; from a perfectly pellucid colourless state, it passes by different gradations to opacity; but all the varieties, except flinque, admit light through the very minute fragments. The colours are various, owing to the impregnation or mixture with foreign substanaces. The specific gravity of quartz is from 2.58 to 2.65. It yields a phosphorescent light when rubbed, and is not soluble in any of the acids except the fluoric. According to Vauquelin, powdered quartz gives a green colour to tincture of violets. Crystallized quartz presents the phenomenon of double refraction, when an object is seen through one side of the pyramid that terminates the crystals, and the opposite side of the hexagonal prism on which it is placed, in the most common variety of the secondary forms of these crystals.

The substanances found imbedded in quartz are, ores of titanium, antimony, gold, silver, copper, and lead, arsenic, and micaeous iron ore, with chlorite, hornblende, felspar, garnet, and fluat of lime. It is also penetrated by fibres of aebillus, and by minute laminae of niva and epidote; the latter substanance is sometimes os intately diffused through quartz as to give it an homogeneous green colour. This variety of quartz is called grafe.

Quartz crystallizes distinctly; some of the crystals are of considerabe size.

In the imperial cabinet of Vienna, there is said to be a crystal of quartz seven feet in length. The forms of crystalline quartz are various; they have been reduced by modern mineralogists to six or seven principal varieties. The most common is a fix-sided prism, terminated by a fix-sided pyramid, or two fix-sided pyramids joined at their bases. The sides of these pyramids are isofaces triangles, having the vertical angle 45°, and each of the angles at the base 70°.

The sides of the upper and lower pyramids are inclined to each other at an angle of 104°. According to Hauy, the primitive form of the crystal is a rhomboid, varying little from the cube, the angles being 94° and 86°. The primitive rhomboid is rarely found in nature; it occurs sometimes in red hematite, coated with that mineral, and in chalcedony.

Bubbles containing air, water, and bitumen, are sometimes seen in quartz crystals, and have given rise to much speculation respecting their formation. Siliceous earth, of which these crystals are composed, is insoluble in water, by artificial means; but in the great laboratory of nature, its solution is effected probably by the effect of heat and compression, as fiesex exits in the boiling fountains of Island and the Azores, and in the hot springs of Bath, Italy, and various parts of the world. It has been supposed that the siliceous earth was held in solution by foda; but Klaproth, who analyzed the waters from the Reikum, in Iceland, thinks the quantity of alkali too small to have diffused the fiesex.

One hundred cubic inches contained nine grains of fiesex, three of carbonate of foda, eight of common salt, and five of sulphate of foda. If rock crystals were formed in an aqueous solution greatly heated and compressed, it would not be difficult to conceive how volatile matter might be involved in the substance of the crystal during its formation; but our knowledge of the subterranean operations of nature is at present too limited to enable us to ascertain, or even to form any rational conjecture in what manner some of her more myerious processes are effected. Those who have frequent opportunities of exploring mines, will not be disposed to deny that siliceous flasquets, and crystals, are now forming at the common temperature of the earth, as they are observed.
QUARTZ.

served on the roofs and sides of artificial excavations, and
pallets which have been undisturbed for some years. According
to Chaptal, a quartz stope is formed by the
transformation of ferruginous rocks at Chamillat, near Planches
les Mines, in Franche Comté, and where this is washed and
deposited by water, rock crystals are formed. Siliceous
flaecles have not infrequently been seen coating the wood
which has been left in mines.

Pleomorphic crystals of quartz, or false crystals of
this mineral, are frequently found in mines; they are
prismatic and opaque, and their edges are blunted. They
assume the forms of cubic crystals of fluor, and the pyra-
midal and other forms of calcareous and other crystals.
These false crystals are evidently moulded in the cavities
which the former have once occupied. Quartz also occurs
filling up the cavities of shells in a similar manner, and the
poles of wood and other organic substances.

Cellular quartz with polyhedral cavities, appears to have
been formed round crystals of other minerals which are sub-
sequently decomposed. The internal crystals are frequently
those of the metallic sulphures. Brongniart says
this conclusion is founded on direct observation, as the re-
maind found in these cavities are sulphur, native gold, and
oxyd of iron, all sulphures which originally formed part of
the decomposed sulphures. Such is the cellular quartz at
Schemnit in Hungary, and Joachimsthal in Bohemia. The
cellular quartz at Berezof, in Siberia, is so porous that it is
lighter than punice.

Rock crystal, or Mountain crystal, is the purest form of
quartz, differing from common quartz by its transparency,
and the more regular form of its crystals; the fracture is
also more perfectly conchoidal. According to some analyses,
rock crystal contains 98 parts of silica, with 2 parts of
water. Bergman found in one specimen only

Silex - 93
Alumine 6
Lime - 1

Amethyst is a purple variety of rock crystal. See Am-
ethyst.

Caïmgorum stones are rock crystals, from the mountains
of Caïmgorum, in Scotland. They are valued by jewellers
on account of their piquancy and colour. Close-brown quartz
crystals are known by the name of the smoke topaz. Ac-

cording to Kauffen, the specific gravity of this variety is
2.88. Coloured rock crystals lose their colour, when care-
fully exposed to a gentle heat, but retain their transparency.
The yellow and orange-yellow varieties are the most
esteemed.

Milk quartz, called by some mineralogists rofe quartz,
and by others the Bohemian ruby, as it is frequently of a
beautiful rofe-red colour, which it derives from manganese.
By exposure to the light the intensity of its colour is dimi-
nished. It is used in jewellery, and takes a good polish; it
is sometimes cold for the ruby, but is less hard, nor has it
the transparency and brilliancy of that gem. Rose quartz
is found at Rabaudcun, in Bavaria, in considerable masses,
and in a vein of manganese which traverses a coarse-grained
granite. It occurs also in Sweden, Greenland, Saxony,
in the island of Coll, one of the Hebrides, and in Ireland.
Some varieties are of a milk-white colour, others pearl-grey.

Iridescence quartz, Quarz hyalin irides, presents on its sur-
face, or in its interior, the various colours of the rainbow:
it sometimes derives this property from a thin pellicle of me-
tallic oxys which covers the surface, and sometimes from
minute tints in the substance of the crystal. Thee colours
may be given to quartz by heating it and exposing it fud-
denly to a cold temperature.

Avanturine quartz (see Avanturine) owes its brilliancy

to minute particles of mica disseminated through it, and
sometimes to minute fractures. Avanturines may be formed
artificially, in some varieties of quartz, by heat.

Blue quartz, Quarz blau, has been found in
Spain, Bohemia, and Bavaria.

Black quartz is found, mixed with carbonate of lime, in
the department of Ile in France, in Bohemia, and at
Cappe Nuova, on the road to Sienna. Brongniart Min-
eralogic.

Cat's-eye, Quarz hyalin chatoyant, so called because it re-

dicts a pearly variety of colours, according as the light falls
upon it in different directions: this property is owing to the
fibrous texture of this mineral, which may be observed in
the bulk characterized specimens. It contains 95 parts of
silica, and according to Brongniart is a variety of quartz, and
ought not to be classed with falfpar. The geological fution
of this stone is not known. The cut and polished specimens
seen in cabinets come from Malabar and Ceylon. It is
said, also, to occur in Egypt and Arabia.

Green quartz, Prat, Quarz hyalin verd olfre. The colour
is a leek green; it is seldom crystallized; the form of the
crystals are those of common quartz. Prat has been said
to owe its colour to an intimate intermixture with alumin-
lite, but Klaproth is of opinion that this is not well ascer-
tained.

Sapphire is classed, by some mineralogists, with quartz. It
is of a deep blood-red colour, and perfectly opaque, or
barely transmits light on the edges. It resembles red jasper,
but has a vitreous lustre, and conchoidal fracture, and is
sometimes crystallized.

Ferruginous quartz consists of small crystals, or of granu-
lar quartz, intimately mixed with oxys of iron, and has a
brown ochre-yellow, or red colour. From the iron which
it contains it becomes magnetic when heated. It is harder
than pure quartz.

Certain properties, beside colour, have given names to
some varieties of quartz.

Fat quartz is so called because it has a greasy appearance,
as if the surface had been rubbed with oil.

Felid quartz differs from common quartz, by emitting an
odour when rubbed, like that of sulphured hydrogen gas.
When this folii is heated below a red heat, it loses
its fetid odour on cooling, and when plunged into water be-
tcomes transparent. When fetid it is nearly opaque. It is
found in the vicinity of Nantes and Chantilly, in the
department of Haute Vienne, forming a constituent part of
the granite mountains of that district. It occurs also in
the island of Elba.

Elatic quartz is a silicious sand-stone, found in the Bra-
zils, composed of oblong laminate of quartz, arranged in
one direction, and so interlocked together as to form a kind
of hinge with each other, from whence it polishes a certain
degree of pliability, like that of a stiff piece of leather. In
appearance, elastic quartz resembles some of the flaty sand-
stones in the northern counties of England. According to
Klaproth its constituent parts are

Silex - 96.50
Alumine - 2.50
Oxys of iron and lofs 1

The use of quartz in the arts is principally confined to
the manufactures of glafs, enamels, porcelain, and earthen-
ware. The finer crystallizations are employed by the jewel-
ners, and before the discovery of glafs, ornaments and veils
of great value were made by the ancients from rock crystal.
Stones in which quartz forms the principal ingredient, are
belt fitted for purposes of durable architecture, and in the
economy
economy of nature this mineral gives liability to the solid fabric of the globe, enabling those rocks and mountains in which it abounds to resist the decomposing effects of air and moisture, and to brave for ages the impetuous fury of the ocean. For the properties of flax, of which quartz is composed, see Silex.

QUARTZ, in Geology. Entire rocks and even mountains are composed of quartz in various parts of the world, in the vicinity of granitic districts. The quartz is granular, and sometimes intermixed with a small portion of mica. Werner calls quartz rock as a distinct order of primary rocks, but it would be perhaps more conformable with a natural arrangement, to consider this rock as a constituent of granite on a large scale, certain causes having separated the quartz, mica, and felspar into distinct masses. Entire mountains of these three substances are laid to occur in the Urallian chain, presenting the materials of granite on a large scale. Quartz rocks are met with in Scotland. In the highlands the summits of some of the mountains are formed of white quartz, and appear as if covered with snow. The two beautiful conical mountains, called the Sugar-loaves, in the vicinity of Dublin, are composed of granular quartz, of a similar kind to what forms veins in the gneiss and mica flake of the surrounding mountains nearer Dublin.

QUARTZ, in Mineralogy. A term applied to these rocks or minerals which are principally composed of quartz.

QUASHING, in Law, the overthrowing and annulling a thing. Thus, pleas in abatement (which fee), when the suit is by original, conclude to the writ or declaration; by praying "judgment of the writ, or declaration, and that the same may be quashed," cauteth, made void or abated; but if the action be by bill, the plea may pray "judgment of the bill," and not of the declaration; the bill being here the original, and the declaration only a copy of the bill. See Plea, Dilatory Pleas, and Certiorari.

QUASI-CONTRACT, in the Civil Law, an act which has not the strict form of a contract, but yet has the force of it.

In a contract there must be the mutual consent of both parties; whereas, in a quasi-contract, one party may be bound or obligated to the other, without having given his consent to the act by which he is obliged.

For an example: I have done your business in your absence, without your procuration; and it has succeeded to your advantage; I have then an action against you for the recovery of what I have disbursed; and you an action against me, to make me give an account of my administration; which amounts to a quasi-contract. See Contract.

QUASI-CRIME, or QUASI-DELICT, the action of a person who does damage, or evil, involuntarily.

The separation of quasi-crimes confineth in making good the damages, with interest.

QUASI-MODO SUNDAY, Law Easier-Sunday, or the next funday after Easter; thus called from the initial words of the introit of the mafs for the day, Quasi modo geniti infantes.

In the ancient deeds these words are signified by g. m. g.

QUASS, the name of a liquor in Russo, which laves the natives not only for drink, but also for sauce to a number of dishes; and is the basis of the favourite cold soup of the North, which is made by adding cold meat cut in pieces, with cucumbers salted after a peculiar manner, or with onions, or garlic, to a bowl of this acid liquor. The common Russian quass is prepared by putting into a large pot full of cold water as much rye-flower as will make a thin dough; this is then placed in an oven moderately heated, for three hours, and afterwards taken out and thrown into a tub of cold water; the mixture is worked with a machine like a chocolate mill till it froths. To this liquor are added two baloons of the grounds of old quass, leaven, or a piece of their four bread; and the tub is covered with a cloth, and laid by till the liquor has acquired a fourish taste, which marks its being ready for use.

There is a better sort of quass, which is prepared as follows. Take a cheverik (about 35 pounds Ruff. or 39 pounds Engl.) of barley-malt, two or three handfuls of rye-malt, and a like quantity of unboiled rye-meal; mix them all together in earthen pots, then pour boiling water upon it, and stir the while till it acquires the confection of a thin pap. The pots must be full to within an inch of the brim. Upon this mixture must now be poured about an inch in height of the husks of oats, from which groats are made. Set the pots in a heated oven, in which some glowing coals are still remaining, which must be heaped about the pots. This done, clofe the oven, and leave the pots in it four-and-twenty hours. This time being elapset, take them out; again pour boiling water in till they are brimfull, and stir all well together. Now pour it all into a wooden vessel or tub, provided with a spigot and follet, first covering the bottom with a layer of straw, as is usually done in brewing beer; then add warm water, more or less, according to the quantity of quass you want; let it stand an hour, and afterwards draw it off into vessels. In every vessel a slice of coarse rye bread must be put, in order to make it ferment. Set the vessels in a cellar, and after four-and-twenty hours the quass is fit for drinking.

In making quass, barley-malt alone may be used. The rye-malt is added only from necessity, when the former, by itself, would be too poor, and not be sufficiently sweet. But the rye-malt is absolutely necessary.

From the quantity of malt and meal above stated, is obtained about five or seven kilderkins, or two ands of quass. The Ruffians in the summer season put the vessels of quass immediately in the cellar, but in the winter they let them stand a whole night in a warm room, for the quass to ferment.

QUASSE, in Geography, a town of Africa, in Benin. N. lat. 6° 20'. E. long. 3° 30'.

Gen. Ch. Cal. Pernath inferior, very short, of five ovate, permanent leaves. Cor. Petals five, fiddle, equal, lanceolate, elongated, oblique, converging. Nectar of five ovate villous scales, attached to the inside of the filaments at the base. Stem. Filaments ten, thread-shaped, equal, the length of the corolla; anthers oblong, incumbent. Pet. Receptacile fleshy, elevated, orbicular, broader than the germ. Ovate ovate, composed of five separate ones; stylo thread-shaped, with five furrows, the length of the filaments; stigma with five angles. Perf. Drupas five, distant, horizontal, ovate, obtuse, splitting into two parts, all standing on a fleshy pentagonal receptacle. Seeds solitary, globose or oval.

Obi. Some flowers have abortive germens, others imperfect authors.
QUASSIA.

1. Q. amara. Bitter Quaffia. Linn. Sp. Pl. 553. Suppl. 235. Amoen. Acad. v. 6. 416. t. at pag. 420. Willd. n. t. Ait. n. t. Curt. Mag. t. 407. Woody. Med. Bot. t. 77. —Flowers all perfect. Leaves pinnate; leaflets opposite, feliile; common falk jointed, winged. Flowers racemose.—Native of Surinam. Introduced in 1790, by Mr. Alexander Anderson, to the ffoves at Kew, where it flowers in June and July. A fbrub rather than a tree, whose wood is intensely bitter. Leves alternate; of two pair of leaves, with an odd one, all elliptic-lanceolate, pointed, entire, veinly, very smooth, two or three inches in length, on a linear winged falk, abrupt and jointed at the infenion of each pair. Cluflers long, drooping one way. Flowers numerous, above an inch long, not much expanded, of a rich fcarlet, as well as their falks. The younger Linnean errors in faying, in the Supplement, that the branch figured in Am. Acad, does not belong to the flowers.

This is the true original Quaffia, whose wood is more powerful than that of the other species; but being very rare, and of small bulk, its place is paid to be ufually supplied by Q. eclefla hereafter defcribed.

2. Q. Simaruba. Wing-leaved Quaffia. Linn. Suppl. 234. Willd. n. 2. Ait. n. 2. Woody. Med. Bot. t. 76. (Simarouba amara; Aulb. Guian. v. 2. 859. t. 331. 332.)—Flowers monoeous. Leaves pinnate; leaflets alternate, not quite felliile; common falk naked. Cluflers panicked.—Native of various parts of the Wett Indies, in a fandy feld, flowering in November and December. It was fent to Kew in 1787, by Mr. Alexander Anderson, but has not bloomed there. This is a tall and fluey tree, whose wood is hard, white, without any peculiar flavour. Leaves alternate, with fix, feven, or eight alternate obovate, rather narrow, entire, flaked leaflets, two inches long, white, fliiileth thick fheat; their common falk fimple, roundifh. Flowers yellownifh-white, much smaller than the preceding, either monoeous, or, as fome fay, dioceuus, in branched or panicked cluffers. The bark of the root is bitter, and much celebrated as a cure for the dyftery. Dr. Wright has given a full history of the plant, with a plate, in the Tranfactions of the Royal Society of Edinburgh, vol. ii. It is known in Jamaica by the name of Mountain Damfoon, Bitter Damfoon, and Swayne-wood. In that ifland, according to Dr. Wright, the male flowers are never found on the fame tree with the female.

3. Q. excelfa. Lofty Quaffia. Swartz in Stockh. Tranf. for 1788. 302. t. 8. Ind. Occ. v. 2. 742. Willd. n. 3.—Flowers polyanuous. Stamens five. Leaves pinnate; leaflets opposite, flaked; common falk naked.—Native of rather mountainous woods, in Jamaica and the Caribbean iflands. The English commonly call it bitter wood, or bitter afi. The tree is lofty, with a very ftraight trunk; the wood whifli, moderately clofe-grained, very bitter; frequently fold by the druggists for the true Quaffia amara, and found ufeul in interrupten fteams, debility of the form, worms, dropey, and chorofis. It is also ufed for making cabinets, for preserving infects, or other natural curifies; this wood being fuppoled inaccessiile to worms. The leaves are larger than the falt, and compos'd of from four to fix pair of opposite, elliptical, pointed, firm, entire, smooth leaflets, on short partial falks. Cluflers panicled, bearing very numerous, small pale flowers, fome male, the rest hermaphrodite, in the fame clufler. Swartz describes the neeey, of five minute vilious fcales, contrary to the remark of Willdenow, under his Zvingera, Sp. Pl. v. 2. 569, where it is laid to be wanting in this species of Quaffia. The flowers are moftly five, rarely four or fix. Germs from two to four.

QUASSIA Amara, bitter quaffia, in the Materia Medica. The root, bark, and wood of this tree are all comprehended in the catalogue of the Materia Medica; and it is observed that the leaves, flowers, &c. poffefs similar qualities. The roots, being perfectly ligeous, may be medically confidered in the fame light with the wood, which is now most generally employed, and seems to differ from the bark in being less intensely bitter; fo that the latter is thought to be a more powerful medicine. The wood is fent to this country from Jamaica and the Caribbean iflands in billets; and is reduced to chips, or rapped by the druggists. Quaffia has no fenible odour; its tafle is that of a pure bitter, more intense and durable than that of any other ftubance. It imparts its virtues more completely to watery than to fpitious meffrum, and its infusions are not blackened by the addition of martial vitriol. When the infusion is evaporated to dryness, it leaves a brownifh-yellow, somewhat transpar- rent, brittle extract, which has been regarded as a vegetable constituent fui generis, and named the bitter principle. (Edinb. Phil. Tranf. iii. 207.) The infusion is rendered mudder by nitrate of silver, and a foft, flaky, yellow precipitate is formed; acetate of lead occasions a copious white precipitate; and hence it has been inferred that these falt is incompatible in formula with it. The water extract is from a fixth to a ninth of the weight of the wood; the fpitious about a twenty-fourth.

Quaffia derived its name, as has been already obferved, from a negro named Quaffi (by Fermor, written Coiff, and by Rolander, Quafla), who employed it with uncom- mon fucces as a secret remedy in the malignant, endemic fevers, which frequently prevailed at Surinam. In confequence of a valuable confideration, this secret was difclofed to Daniel Rolander, a Swede, who brought fpecimens of the quaffia-wood to Stockholm in the year 1756; and since that time the effects of this drug have been very generally tried in Europe, and numerous testimonies of its efficacy published by many reputable authors. Its antifeptic powers have been submitted to various trials, from which it has been concluded, that it has confiderable influence in retarding the tendency to putrefaction; which, in professor Murray's opinion, cannot be attributed to its fenible qualities, as it poifoes no atringency whatever, nor to its bitternefs, as gentian is much more bitter, but lefs antifeptic. The medicinal virtues ascribed to quaffia are thofe of a tonic, fomachic, antifeptic, and febrifuge: it has been found very efiectual in reiling the tone of the stomac, producing appetite for food, affiling defolucion, expelling flatuency, and removing habitual colic, produced from debility of the intellines, and common to a fedentary life. Dr. Letfom obferves, that in hyfcrical atony, to which the female fex is fo prone, the quaffia affords more vigour and relief to the fyttern than the Peruvian bark, efpe- cially when united with the vitriolum album, and ill more with the aid of fome abforbent. In dyspepsia, arising from hard drinking, and also in diarrhreas, he exhibited the quaffia with great fucces. Although he does not concur in opinion with Linneus, who fays, "me quidem judice chinichimam longe superat;" yet he has met with feveral infances of low remittent and nervous fevers, the fymptoms of which the bark uniformly aggravated, though administered in inter- mittent, it is the moft favourable to its fucces, in which quaffia, unlike bark, was exceedingly fublime. In fuch cases, he molly obferved that there was great cough in the haf- tic fyttern, and the debility at the fame time difcouraged copious evacuations. And in many fevers, without evident remiffions.
Qua

remissions to warrant the use of the bark, whilst, at the same time, increasing debility began to threaten the life of the patient, the doctor found that quassia, or snake-root, finely or combined, upheld the vital powers, and promoted a critical intermission of fever, by which an opportunity was offered for the bark to effect a cure. Dr. Cullen says, (Mat. Med. vol. ii. p. 174, “I believe quassia to be an excellent bitter, and that it will do all that any pure and simple bitter can do; but our experience of it in this country does not lead us to think it will do more; and the extraordinary commendations given of it are to be ascribed to the partiality so often shown to new medicines.” It is said to have been given, combined with nitric acid, with evident benefit in typhus, and also in fluxus album. It may be given in infusions, which is the best form of administering it; or in pills made from the watery extract. It may also be given in substance in doses of from grs. x to 3; three or four times a day.

The official preparations are the “infusium quassiae” of the London Pharmacopoeia, and the “tinctura quassiae” of that of Dublin. The infusion is prepared by macerating for two hours in a lightly covered vessel a scarpell of quassia-wood, chipped, in half a pint of boiling water, and straining. In hydromyisis, this may be combined with purgatives and tincture of valerian; in atomic gout, with aromatics; and in dyspeptic affections, with chalybeates, sulphate of zinc, or mineral acids. The dose is from $\frac{1}{3}$ to $\frac{1}{2}$ of a grain, given twice or thrice a day. The tincture is prepared by digetting for seven days an ounce of chips of quassia-wood in two pits of proof spirit; and then straining. This may be used in the fame caes as the infusion.

It is asserted that the brewers have, of late years, used quassia-wood instead of hops. Beer made with it certainly does not keep, says Thomson, but soon becomes muddy and flat, has a mawkish taint, and runs into the acetous fermentation. It is consequently less nutritious and wholesome than that which is properly hopped. Wood. Mat. Med. Thomson’s Lond. Diph.

Quatrofoil, a decoration resembing a rose with four leaves, which constantly occurs in pointed architecture.

Quatre-Nations, q.d. Four Nations, the denomination of a college founded in 1661, by cardinal Mazarin, for the education and maintenance of sixty children, natives of the four countries conquered by Lewis XIV., viz. fifteen for Pignerol and Italy, fifteen for Alfatta, twenty for Flanders, and ten for Rouffillon.

Quatrichroma, in the Italian Music, is what we call a demi-femi-tarver, thirty-two of which make a bar in common time. See Time, and Triple.

Quatro Case, in Geography, a town of Italy, in the department of the Mincio; 17 miles S.E. of Mantua.

Quatros, Coronados, Los, an isand in the Pacific ocean, discovered by Quiros in 1606. S. lat. 18° 40’.

Quattrino, in Commerce, a copper coin at Florence; also a money of account, 60 quattrini being equal to 12 crowns, 1½ paoli, or 2 lira. At Rome, the feco is divided into 3½ tettoni, 500 quattrini, or 1000 mezzz quattrini; so that 5 quattrini make 1 paolo, and 3 paoli 1 tettoni. See Scudo.

Quatuor, Lat., a name given to any musical composition, vocal or instrumetal, in four parts, and in dialogue, or a parte equale, when each have solo parts alternately. The Italians sometimes call a quatuor quartello, but more frequently quartetto, and the English quartё.

A vocal quartet, says Rouelle, is more difficult for the poet to write, as well as for the composer to fet, than a trio or chorus.

In the vocal quartet of a musical drama, four distinct characters should be supported both in the words and music, according to the situation and state of mind of the several personages who have petitions or complaints to make, or answers to give.

The instrumental quartets of Haydn have been the delight of all that have performed, or heard them performed, for full 30 years, and bid fair to continue to afford delight for at least 30 years more.

Qualetor Principalia Artis Musices, the title of a MS. in the Bodleian library at Oxford (Digby 90.), which has been ascribed to several authors. Anthony Wood gives it to Tewkebury, to whom it is likewise ascribed in the Oxford Catalogue of MSS. with very little foundation. Bishop Tanner has honoured Dr. John Hambois with this production, a writer on music, who flourished more than a century after this MS. was finished, as appears from the testimony of the scribe himself.

There is, however, at Oxford, among the MSS. another volume of Musical Tracts (Bodl. 515.), which had not been sufficiently examined by any of the cataloguers who have mentioned it; for, on a careful perusal and collation, we found in it, besides two other tracts by Simon Tunfled, or Tulle, a duplicate of the Qualetor Principali; and as no doubt has been thrown upon Tunfled having been the author of the two first tracts in the volume, it seems as if we might venture, without doubt or hesitation, to affign to him this amble, and, for the time when it was written, excellent treatise. That Simon Tunfled was a man of science, and an able musician, as well as a doctor of divinity, appears at the end of MS. Digby 90. After saying that the book was finished in 1531, we have the following passage: “Ille autem anno regis erat inter ministros Oxonienses, Simon de Tunfled, doctor sacrae theologiae, qui in musica pollubat, et eciam in septem liberalibus artibus.” Pits, Bale, Tanner, and all our biographical writers, speak of him as a learned musician; and Pits enumerates the Qualetor Principali among his writings. (De illuit. Angl. Script.) Simon Tunfled, a Franciscan friar, born at Norwich, was in such favour for his learning and piety, as to be
be unanimously chosen provincial master of all England. He died at Brazen, in Suffolk, in 1360.

The title of the work in the Oxford Catalogue of MSS. has occasioned the great diversity of opinions about the writer of the Quatuor Principali; for No. 515 is entitled "De Musica continua et discreta, cum Diagammatibus, per Simonem Tunfedo, A.D. 1351." However, in the beginning of the volume, the author proposes to treat "De quatuor Principalius in quibus vocis Musicæ radicis constat," &c. which exactly agrees with the other MSS.; and there is no difference from the beginning to the end, except in the omission of a kind of prologue, or argument to the work, which appears in the tract ascribed to Tewkesbury (Digby 90.), beginning "Quemadmodum inter Trichitum," and is omitted in that to which the name of Tunfedo is prefixed. Bodl. 515.

What the author calls the "Four Principals of Music," will best appear from his own manner of dividing the work. In the first part or principal, consisting of nineteen chapters, he treats of music in general, its constituent parts and divisions. 11. Of its invention, intervals, and proportions, twenty-four chapters. 111. Of plain chant, and the ecclesiastical modes, fifty-eight chapters. IV. Of measured music, or time; of diatonic, and their several divisions. This last principal is divided into two sections, of which the first contains forty-one chapters, and the second forty-nine. The whole treatise fills a hundred and twenty-four folio pages; the diagrams, which are very numerous, are beautifully written, and illuminated with different coloured inks; and it seems to be in all respects the most ample and complete work of the kind which the fourteenth century can boast.

Quatru Principis Propositid. See Prepositi.

Quatuor-Vir in Antiquity, frequently written III. Vir, a Roman magistrate, who had three colleagues joined with him in the same administration.

To the quatuor-vir was committed the charge of conducting and settling the colonies sent into the provinces.

Upon unhappy accidents, and other dangerous affairs, it was usual to create quatuor-vir, with commission to take care ne quid detritum repulsus caperet, ... not prejudiced.

There were also quatuor-viri appointed to inspect and take care of repairs, &c.

Quauchochopitli, in Ornithology. See Picus Tricolor.

Quaver, in Musica, a measure of time, equal to one-half of the crotchet, or one-eighth of the semi-breve.

The quaver is marked by the character

The English quaver makes what the French call crochets, crotchet, because of the hook at bottom. See Crotchet.

The quaver is divided into two semiquavers, noted and four semifemiquavers, marked. See Characters.

Quaverina, the act of trilling, or shaking; or the running a division with the voice.

Quauhtoyuhatli, in Botany, a name by which some authors have called the tree, whole fruit is the calla filuta of the pods. Hern. p. 87.

Quauhchilui, in Ornithology. See Merops Gignorus.

Quauhiyamatli, in Zoology. See Sus Ta-

Quauhtecalloquilapachtli. See Securis Variegatus.

Quauhtechalott-thlittic. See Securis Niger.

Quauhtla-coyomatli. See Sus Tajaful.

Quauhtzecolin, in Ornithology, the American name for a bird called by most a quail, but esteemed by Nieermberg a species of partridge.

It is of the size of the European partridge, and of a brownish colour, and ornamented with a crest upon its head.

There are also in America two other species of partridge much allied to this: the one with a yellow body, and black and white head; the other small and brown, and without a crest. See Tetrao Cirratus.

Quauhyac Occilensium, in Botany, the name of a very large Indian tree, bearing leaves resembling those of the citron. The bark is aromatic, heating, drying, and of a strong smell: it refreshes a diarrhoea, and excites a sweat. The juice, boiled up the nose, caues freezing, purges the head, and thus removes fivers, and pains in the head: for which reasons, it is preferred in families as a popular remedy. Nieermberg.

Quavitl, a name given by some authors to the cocoa-
tree. Hern. p. 79.

Quautotopotli, in Ornithology. See Picus Canadensis.

Quay Kay, a space of ground paved on the shore of a river, or port, defined for the loading and unloading of merchandise. See Kay and Wharf.

Queaga, in Geography, a town of Pegu, on the Ava; 18 miles S. of Lundsey.

Quebec, a city of America, the capital of the lower province of Canada, as Niagara is of the upper, was founded by the French in the year 1628, and is situated on a very lofty point of land, on the N.W. side of the river St. Lawrence, at its confluence with the river St. Charles, about 320 miles from the sea. Nearly facing it, on the opposite shore, there is another point; and between the two the river is contracted to the breadth of three-quarters of a mile; but after passing through this strait, it expands to the breadth of five or six miles, taking a great sweep behind that point on which Quebec stands. The city derives its name from the word Quebec, or Quebe, which, in the Algonquin tongue, signifies a sudden contraction of a river. The wide part of the river, immediately before the town, is called "the Baftom," and it is sufficiently deep and spacious to float upwards of 100 sail of the line. Quebec is divided into two parts, called the upper and the lower towns. The upper town is situated on a rock of limestone, on the top of the point; and the lower town, built round the bottom of the point, close to the water, on land which has been gradually gained from the river. The rock on which the upper town stands rises, in some places, towards the water, nearly perpendicular, so as to be totally inaccessible; in other places it is not so steep as to prevent a communication between the two towns, by means of streets winding up the side of it; though here the ascent is so great, that there are long flights at one side of the streets, for the accommodation of foot-passengers. The lower town lies very much exposed to an enemy, being defended merely by a small battery towards the baflom, which, at the time of high tides, is nearly on a level with the water; and by barriers towards the river, in which guns may be planted, when there is any danger of an attack.

The upper town is a place of immense strength. Towards the water it is so strongly guarded by nature, that flight
flight walls are a sufficient defence; and in some places, where the rock is inaccessible, no walls are necessary. Here, however, are several redoubts and batteries. The principal battery, which points towards the baion, consists of twenty-two 24-pounders, two French 36-pounders, and two large iron mortars; this battery is flanked by another of fix guns, that commands the pales from the lower town. On the land side the fortifications are stupendous. When general Wolfe attacked this place, he thought it a vain attempt to make an assault on the side of the town which lies towards the water, where the rock is so steep, and so easily defended. In order to carry on the attack on the land side, he first attempted to land his troops some miles below the town, near the Falls of Montmorenci; but here he was repulsed by a large division of the French forces with losses. Foiled in his first attempt to get on shore, the brave Wolfe formed the bold design of ascending to the top of the banks above Quebec, commonly called the Heights of Abraham. After previous preparation, the sappers clambered up the heights with great difficulty, and the guns were hauled up by means of ropes and pulleys fixed round the trees, with which the banks are covered from top to bottom. At the top the plain commences, and extends close under the walls of the city. Here the memorable battle was fought, in which the much lamented general fell, at the moment when all his noble exertions were about to be crowned with the success which they so eminently merited. The spot where the illustrious hero breathed his last is marked with a large stone, on which a true meridional line is drawn. Although the great Wolfe found it so difficult a task to gain possession of Quebec, and it has been rendered much stronger since his time, the people of the United States imagine, that, in case of a rupture with Great Britain, it might be easily taken; and yet it is so strong that the town was never attacked by the enemy, and the inhabitants are never oppressed with riot in summer; it is, however, far from being well laid out, the streets being narrow and very irregular. The houses are generally built of stone, and, except some few, built of late years, small and inconvenient. The chateau, in which the governor resides, is a plain building of common stone, situated in an open place, the houfes round which form three sides of an oblong square. It consists of two parts. The old and the new are separated from each other by a spacious court. The former stands just on the verge of an inaccessible part of the rock; behind it, on the outside, there is a long gallery, from whence, if a pebble were let drop, it would fall at least sixty feet perpendicularly. This old part is chiefly taken up with the public offices, and all the apartments in it are small and ill contrived; but in the new part, which stands in front of the other, facing the square, they are spacious, and tolerably well finished, but none of them can be called elegant. This part is inhabited by the governor's family. The chateau is built without any regularity of design, neither the old nor the new part having even an uniform front. It is not a place of strength, as commonly represented. In the garden adjoining to it is merely a parapet wall along the edge of the rock, with embrasures, in which a few small guns are planted, commanding a part of the lower town. Every evening during summer, when the weather is fine, one of the regiments of the garrison parades in the open place before the chateau, and the band plays for an hour or two, at which time the place becomes the resort of numbers of the most genteel people of the town, and has a very gay appearance.

Opposite to the chateau there is a monastery belonging to the Recollets, or Franciscan friars; a very few only of the order are now left. Contiguous to this building is the college belonging to the Jesuits, whose numbers have diminished even fall farther than that of the Recollets.

The nunneries are three in number, and as there is no restriction upon the female religious orders, they are all well filled. The largest of them, called L'Hospital General, stands in the suburbs, outside of the walls; another, of the order of St. Ursule, is not far distant from the chateau.

The engineer's drawing-room, in which is kept a variety of models, together with plans of the fortifications of Quebec and other fortresses in Canada, is an old building, near the principal battery. Adjoining to it stands the
house where the legislative council and assembly of representatives meet, which is also an old building, that has been plainly fitted up to accommodate the legislature.

The armory is situated near the artillery barrack, in another part of the town. About ten thousand stand of arms are kept in it, arranged in a similar manner with the arms in the Tower of London, but, if possible, with greater neatness and more facility. The artillery barracks are capable of containing about five hundred men, but the principal barracks are calculated to contain a much larger number; they stand in the marketplace, not far distant from the square in which the chateau is situated, but more in the heart of the town.

The market of Quebec is extremely well supplied with provisions of every kind, which may be purchased at a much more moderate price than in any town visited by Mr. Weld in the United States. It is a matter of curiosity to a stranger to see the number of dogs yoked in little carts, that are brought into this market by the people who attend it. The Canadian dogs are found extremely useful in drawing burthens, and there is scarcely a family in Quebec or Montreal, that does not keep one or more of them for that purpose. They are somewhat similar to the Newfoundland breed, but broader across the loins, and have shorter and thicker legs; in general they are handsome, and wonderfully docile and sagacious; their strength is prodigious. A single dog will draw a man for a considerable distance, that could not weigh less than ten tons. People, during the winter season, frequently perform long journeys on the snow with half a dozen or more of these animals yoked in a cariole or sledge.

An attempt was made in 1711 by the English and Americans, under the command of brigadier Hill, to surpise Quebec; but it proved abortive. In 1759 it was taken by the English, under the command of the valiant Wolfe, who sacrificed his life in the engagement; and by the peace, in 1763, it was ceded, with the rest of Canada, to the conquerors, in whose possession it has since continued.

The scenery that is exhibited to the view from various parts of the upper town of Quebec, surpasses for grandeur, beauty, and diversity, any other, as Mr. Weld says, that he has seen, either in America, or in any other part of the globe. In the variegated expanses that is laid open before you, stupendous rocks, immense rivers, prodigious expanses of cultivated plains, mountains, lakes, towns, and villages, in turn strike the attention, and the scenes are almost bewildered in contemplating the variety of the scene. Nature is here seen on the grandest scale; and it is scarcely possible for the imagination to paint it to itself any thing more sublime than are the several prospects presented to the sight of the delighted spectator. From Cape Diamond, situated about one thousand feet above the level of the river, and the loftiest part of the rock on which the city is built, the prospect is extended by many as superior to that of any other spot. A greater extent of country opens upon you, and the eye is here enabled to take in more at once, than at any other place; but it appeared to Mr. Weld, that the view from the cape is by no means so fine as that, for instance, from the battery; for in surveying the different objects below you from such a stupendous height, their magnitude is in a great measure lost, and it seems as if you were looking at a draft of the country, more than at the country itself. It is the upper battery that Mr. Weld alludes to, facing the bay, and is about three hundred feet above the level of the water. Here, if you stand but a few yards from the edge of the precipice, you may look down at once upon the river, the vessels upon which, as they fail up to the wharfs before the lower town, appear as if they were coming under your very feet. The river itself, which is between five and six miles wide, and visible as far as the distant end of the island of Orleans, where it loses itself amid the mountains that bound it on each side, is one of the most beautiful objects in nature; and on a fine still summer's evening it often wears the appearance of a vast mirror, where the varied rich tints of the sky, as well as the images of the different objects of the banks, are seen reflected with inconceivable beauty. The southern bank of the river, indented fancifully with bays and promontories, remains nearly in a state of nature, clothed with lofty trees; but the opposite shore is thickly covered with houses, extending as along other parts of the river already mentioned, in one uninterrupted village, seemingly, as far as the eye can reach. On this side the prospect is terminated by an extensive range of mountains, the flat lands situated between the villages and the villages on the banks not being visible to a spectator at Quebec, it seems as if the mountains rose directly out of the water, and the houses were built on their steep and rugged sides.

Beautiful as the environs of the city appear when seen at a distance, they do not appear so on a more close inspection; and in passing through them the eye is entertained with a molten pleasing variety of fine landscapes, whilst the mind is equally gratified with the appearance of content and happiness that reigns in the countenances of the inhabitants. Indeed, if a country as fruitful as it is picturesque, a genial and healthy climate, and a tolerable share of civil and religious liberty, can make people happy, none ought to appear so fine to the Canadians. There are, however, in the vicinity of Canada two scenes, more particularly deserving of attention than any others: these are the falls or cataracts of the rivers Chaudiere and Montmorency; which see respectively. N. lat. 46° 48' 39". W. long. 71° 6' 29". Weld's Travels, vol. i.

QUEBITEA, in Botany, a name which seems to have been whimsically extracted by Aublet, from the Caribbean appellation of this plant, Daguaquebute. Aubl. Guai. v. 2, 528. 1. 327. This has many creeping roots, and a twined, decumbent, hairy stem, with alternate, elliptical, broad, entire, hairy leaves, three or four inches long, on hairy footstalks. Flowers minute, in short, dense, axillary, stalked fies, with a small scale at the base of the stalks. Aublet did not investigate the structure of these flowers, but he supposes the plant to be nearly akin to Dracentum, under which genus it is accordingly noticed by Jussieu. The roots, when chewed, are very agreeable. The bruised herb is used externally, to cure the bite of serpents. It grows on the banks of rivulets in Guiana.

QUEBRANTAHUESOS, in Ornithology. See Procellaria Gigantea.

QUECALA, in Geography, a town in Mexico, in the province of Mechoacan: 125 miles S.S.E. of St. Luis de potofio.

QUECHUA, in Literary History. See Peru.

QUEDA, a sea-port city on the W. coast of the peninsula of Malacca, the capital of a kingdom, tributary to Siam, with a good harbour at the mouth of a river that will admit a vessel drawing 12 or 14 feet water on the spring, or the bar, which is gravel and mud. The town contains about 400 houses, inhabited by Chinees and Malays. The environs are agreeable and fertile; the woods abound in elephants and other animals, and in some places are mines of lead, which supply large quantities of those metals for exportation to Hindoostan, Arabia, and Persia. The go-

vernor
vernment is monarchical, under a Malay Mahomedan prince, who, like many other Malay princes, engrossed almost the whole foreign trade of the port, excepting that of an annual Chinese junk, which pays a certain sum only as duty, and then has leave to trade freely with the inhabitants. This junk imports immense quantities of coarse China-ware, thin iron pans, and many other articles from that country, and exports hich de mer, called swallow, thralls' fins, edible bird's nests, rattans, tin, rice, dammer, tortoise-shell, deer's skins and fines, bullocks and buffaloes' hides and horns, jerked beef, and many other coarse articles. At Queda there is great plenty of rice, bullocks, buffaloes, and poultry; but not such abundance of fruit and vegetables as at Acheen. The territory of Queda is a flat country, favourable for the cultivation of rice; a hill north of the town and inland, called the Elephant, favours the navigator's approach; also the small islands called Peers, 20 miles west of the bar, covered with trees, and good regular mud foundations, a great way off, even by night, indicate the distance to the mariner; 300 miles E.N.E. of Acheen. N. lat. 6° 20'. E. long. 106° 18'.

QUEDENAU, a town of Prussia, in Samland; three miles N. of Königsberg.

QUEDLINBURG, a town of Weiphalia, in the principality of Halberstadt, on the Boda, which divides it into the Old and New Towns. It has several churches, a hospital, and a college. Near this town is a princely abbey, situated on a hill: it was founded by King Henry I. between the years 932 and 936, and since enriched by various endowments. In 1535 it embraced Lutheranism, and obliged itself, by solemn oaths, to maintain that form of religion. It lately confided of four dignitaries, viz. of the lady abbess and three others, distinguished by the titles of provost, dean, and canon. In 1802, the abbey and its revenues were voted to the king of Prussia, as an indemnity; and by the treaty of Tilsit, transferred to the kingdom of Weiphalia. The town of Quedlinburg is seven miles S.S.E. of Halberstadt. N. lat. 51° 48'. E. long. 11° 20'.

QUEDLITZ, a town of Prussia, in the province of Ermeland; four miles S. of Wartenburg.

QUECE, in Agriculture, a term sometimes provincially applied to the wood-pigeon, or birds of that kind.

QUEECHEY, in Geography, a river of Vermont, which runs into the Connecticut at Hartford.

QUEEN, REGINA, a woman who holds the crown of a realm singly, and by right of blood. The word queen is derived from the Saxon reewen, usor, the wife of any one, but applied, by way of excellence, to the wife of the king only; whence she wasanciently called the king's queen; the West Saxons having no other name for a queen but the king's wife. (Ailer de Aelfred, rebus, &c.) She was also called lady, in Saxon coelefic; just as madame, madamefille, were used in France, for the wife and daughter of the duke of Orleans. The name queen is also given, by way of courtesy, to her that is married to the king; called, by way of distinction, queen consort. In respect of whom the former is called queen regnant, or regent.

The widow of a king is also called queen, but with the addition of dowager. In the first sense, queen is, in all construction, the same with king; and has the same powers, prerogatives, rights, dignities, and duties that the king has. This is expressly declared by statute 1 Mar. 1. ft. 3. c. 1.

The queen consort is inferior, and a person distinct from, and a subject of, the king. In England, though she be a feme-covert, yet may she sue, and be sued, in her own name; and may make leaves, and grants, &c. as a femecover.

She has several other prerogatives. Though an alien, she may purchase lands in fee-simple, without either naturalization, or denization; she may prefer to a benefice; nor is plenary a bar against her more than against the king. She is also capable of taking a grant from the king, which no other wife can do from her husband; and she may have a separate property in goods as well as lands, and has a right to dispose of them by will. She pays no toll, and shall not be amerced, if she be nonuit in any action; and may not be impended till first petitioned.

To confine her death, or violate her chastity, is high treason. She has an ancient peculiar revenue, called quin- gold; besides a very large dower, with a royal court, and officers, distinct from the king's; and her attorney and solicitor-general are entitled to a place within the bar of his majesty's courts, together with the king's counsel.

Another ancient perquisite belonging to the queen consort, mentioned by all our old writers, and, on this account only, worthy of notice, is this, that on the taking of a whale on the coasts, which is a royal fish, it shall be divided between the king and queen; the head only being the king's property, and the tail of it the queen's. One reason of this whimsical division, as ascribed by our ancient records, was to furnish the queen's wardrobe with whalebone.

The queen dowager, as the widow of the king, enjoys most of the privileges belonging to her as queen consort. But it is not high treason to confine her death; or to violate her chastity, because the succession to the crown is not thereby endangered. Yet still, pro dignitate regali, no man can marry a queen dowager without special licence from the king, on pain of forfeiting his lands and goods. She has also this particular, that she loses not her dignity, though the marry a private gentleman; as peeresses dowager do their peerage, when they marry commoners. Thus queen Catherine, widow of Henry V. being married to Owen ap Tudor, efq. maintained an action as queen of England. Much less does a queen regnant follow her husband's condition, or is subject to other queens; but she is sovereign to her own husband, as queen Mary was to king Philip, and queen Anne to prince George of Denmark; unless it be otherwise appointed by parliament. The husband may be guilty of high treason against her; but in the instance of conjugal infidelity, he is not subject to the same penal restrictions. For which the reason seems to be, that if a queen consort is unfaithful to the royal bed, this may be a reason or barrenize the heirs to the crown; but no such danger can be conseqent in the infidelity of a husband to a queen regnant.

QUEEN CAROLINE, in Biography, when princes of Wales, is told in the dedication of the opera of Julius Cesar to her royal highness, that the first musical sounds which her highness heard, were those produced by the voice of the celebrated Plutonious, the father of good taste, then in the service of his illustrious prince, at the court of Amphi.

Music doubtless was a ferious part of her majesty's education, as it is, and has ever been, of the princes and princesses of Germany; who have likewise frequent opportunities of hearing great performers and splendid performances; yet we do not recollect having heard that her majesty was a performer herself, or even an admirer or patron of the art. This princess died in November 1737.

QUEEN MARY. (See Mary.) During the short reign of this bigoted and intolerant princes, ecclesiastical music was
again transferred to Latin words and the mafs, both of which had been excommunicated during the reign of her brother, Edward VI. But metrical psalmody had not yet been generally received in our parochial churches. Mary was herself a performer on the virginal and lute, as appears by a letter sent to her by her mother, queen Katherine, after her separation from the king, in which she encourages her to suffer cheerfully, to trull to God, and keep her heart clean. She charged her in all things to obey the king's commands, except in matters of religion. She sent her two Latin books, the one De Vita Christi, and the other the Epistles of St. Jerom: in them, (fays the queen,) I trull you shall see good things. And sometimes, for your recreation, use your virginals or lute, if you have any."

Fuller tells us, that "eight weeks and upwards passed between the proclaiming of queen Mary and her attaining the parliament; during which time two religions were together set on foot, Protestantizme and Popery; the former hoping to be continued, the latter labouring to be restored;—and during this interval the churches and chapels in England had a mongrel celebration of their divine services between reformation and superstition. For the obsequies for king Edward were held by the queen in the Tower, August 7th, 1553, with the dirge fung in Latin, and on the morrow a malle of requiem, and on the same day his corps were buried at Westminster with a solemn service, and communion in English."

In October following the laws of her predecessor, Edward, concerning religion, were all repealed. And in November 1554, bishop Bonner "set up the old worship at Paul's, on St. Katherine's day; and it being the custom, that on some holydays, the quire went up to the fleape to sing the anthems, that fell on that night;—and the next day, being St. Andrew's, he did officiate himself, and had a solemn procecion."

After this period, during the subsequent years of Mary's reign, the public service was every where performed in the Roman Catholic manner, throughout the kingdom; and we may imagine that the numerous compositions to Latin words, which have been preferred of Dr. Tye, White, Tallis, Bird, and the rest of our most eminent harmonists, were composed, performed, and performed at this time, while the Romish religion had the ascendant. And indeed it appears by a record, now in the possession of the Antiquarian Society, that the bell of Mary's chapel establishment contains nearly the same names as that of her brother Edward.

QUEEN ELIZABETH. (See Elizabeth.) In speaking of music during the long and prosperous reign of queen Elizabeth, our nation's honour seems to require a more diffuse detail than at any other time: for perhaps we never had so just a claim to equality with the rest of Europe, where music was the most successfully cultivated, as at this period; when indeed there was but little melody anywhere. Yet, with respect to harmony, canon, fugue, and such labour and learned contrivances as were then chiefly studied and admired, we can produce such proofs of great abilities in the compositions of our countrymen, as candid judges of their merit must allow to abound in every kind of excellence that was then known or expected.

Elizabeth, as well as the rest of Henry VIII.'s children, and indeed all the princes of Europe at that time, had been taught music early in life. For Camden, in giving an account of her studies, says, that "she underflood well the Latin, French, and Italian tongues, and (was) indifferently well seen in the Greek. Neither did she neglect music, so far forth as might become a princeess, being able to sing and play on the lute prettily and sweetly."

There is reason to conclude, that she continued to amuse herself with music many years after she ascended the throne. Sir James Melville gives an account of a curious conversation which he had with this princess, to whom he was sent on an errand by Mary, queen of Scots, in 1564. After her majesty had asked him how his queen drest? What was the colour of her hair? Whether that or her was bold? Which of them two was fairest? And which of them was highest in stature? "Then she asked, what kind of exercises the ufed?" I answered, says Melville, "that when I received my dispatch, the queen was lately come from the Highland hunting: that when her more serious affairs permitted, she was taken up with reading of histories: that sometimes she read her self in playing upon the lute and virginals. She asked if the played well? I said, reasonably for a queen."

"The same day, after dinner, my lord of Hunfiden drew me up to a quiet gallery, that I might hear some music, (but he said, that he durst not avow it,) where I might hear the queen play upon her virginals. After I had hearkened a while, I took by the tapestry that hung before the door of the chamber, and seeing her back was toward the door, I entered within the chamber, and found a pretty space hearing her play excellently well. But the left off immediately, so soon as she turned about and faw me. She appeared to be surprized to fee me, and came forward, seeming to strike me with her hand; alleging, she ufed not to play before men, but when she was solitary, to shun melancholy. She asked how I came there? I answered, as I was walking with my lord Hunfiden, as we passed by the chamber door, I heard such a melody as ravifhed me, whereby I was drawn in ere I knew how: excufing my fault of homefiefs, as being brought up in the court of France, where such freedom was allowed; declaring myfelf willing to endure what kind of punishment her majesty should be pleased to inflict upon me for fo great offence. Then she fate down low upon a cuflion, and I upon my knees by her; but with her own hand she gave me a cuflion, to lay under my knee; which at firft I refufed, but she compell'd me to take it. She enquired whether my queen or fhe played well. In that I found myfelf oblig'd to give her the praife."

If her majesty was ever able to execute any of the pieces that are preferred in a MS. which goes under the name of "Queen Elizabeth's Virginal Book," she muft have been a very great player: as some of these pieces, which were compon'd by Tallis, Bird, Giles, Farnaby, Dr. Bull, and others, are fo difficult, that it would be hardly poiffible to find a matter in Europe, who would undertake to play one of them at the end of a month's practice.

Besides the lute and virginals, Elizabeth was a performer on the violin and on an instrument something like a lute, but large, with wire, and called the psalmeant. A violin of a singular construction, with the arms of England, and the crest of Dudley, earl of Leicetler, this queen's favourite, engraved upon it, was purchafed at the fale of the late duke of Dorset's effeots. The date of its make, 1578. It is very curiously carved; but the several parts are fo thick and loaded with ornaments, that it has not more tone than a mute, or violin with a ready; and the neck, which is too thick for the grip of the hand, has a hole cut in it for the thumb of the player, by which the hand is fo confined, as to be rendered incapable of shifting, so that nothing can be performed upon this instrument, but what lies within the reach of the hand in its first position. Playford
tell us, that "Queen Elizabeth was not only a lover of this divine science (music), but a good proficient therein; and I have been informed, (says he,) by an ancient musician, and her servant, that she did often recreate herself on an excellent instrument, called the poliphant, not much unlike a lute, but fling with wire."

Among the Sloane MSS. in the British Museum, No 1526, there is a list of the officers of the court of revenue in this reign; in which is included the musical establishment of her majesty's household, about the year 1587.

The authors of these compositions were Tallis, Cavilton, Johnson, Oakand, Shepherd, and Taverner.

In 1565, our ecclesiastical composers, encouraged probably by the reception of the former publication, and favour of the queen, printed another collection of offices, with musical notes, under the following title: "Morning and Evening Prayer and Communion, for four parts, to be sung in Churches, both for Men and Children, with harmonious singing in letters or other."

The musicians who contributed to this collection were Thomas Cavilton, Heath, Robert Harleton Knight, Johnson, Tallis, Oakand, and Shepherd.

These two publications by John Day, fixed, for near a century, the style of our choral music; of which the movement was grave, the harmony grateful, and the contrivance frequently ingenious.

The great musicians of Queen Elizabeth's reign were Dr. Tye, John White, Thomas Tallis, William Bird, Dr. Bull, and Thomas Morley. And these, as ecclesiastical composers, were perhaps equal in learning and genius to the greatest contemporary contrapuntists on the continent of Europe.

We must not terminate our account of the cultivation and progress of music by queen Elizabeth and her subjects, without marking honourable mention of her majesty's "Virginal Book," and referring for a summary account of its contents to Bird, William. In all our enquiries after musical curiosities throughout Europe, we have met with no pieces so elaborate and difficult for the harpsichord, as those by our ingenious musicians.

This book, equally valuable for its antiquity and contents, was purchased by Bremner at Dr. Pepusch's sale, 1762, whose property it was to the time of his death. After which it passed into the hands of vicount Fitzwilliams, in whole possession, we believe, it still continues.

It is a magnificent folio MS. curiously bound in red Morocco, with gilt leaves. There are nearly 70 pieces by Dr. Bull in this volume. The writing is small, but uncommonly neat, upon fine lines. The compositions are in general extremely elaborate and difficult; particularly those by Bird, Dr. Bull, and Giles Farnabie, who have all contributed largely to the furnishing of this volume, which contains near three hundred pieces. The first movement in the book is an old English tune, called "Wallingham," beginning in C natural, and ending in A major, which Dr. Bull has varied in a manifold and complicated style, thirty different ways. Signora Margarita, the wife of Dr. Pepusch, when she quitted the Opera stage, applied closely to the practice of the harpsichord; upon which instrument she became a great proficient. However, with all her own diligence and talents, afflicted by the science and experience
of her husband, she was never able to vanquish the difficulties of this piece, by Dr. Bull. And several of Dr. Pecht's friends and pupils, who went frequently to his apartments at the Charter-house, have allured us, that though this manuscript was constantly open upon her harpsichord deck, she never advanced to the end of the variations; as seems likewise manifest from the colour, as well as wear and tear, of the leaves, which are much more clean and entire in every other part of the book, than at the first strain of this composition.

**Queen Mary II.** joint sovereign with William III., seems to have done little more for music, than patronize Mrs. Arabella Hunt, and the old Scots tune of "Cold and raw the wind doth blow." See Mary.

**Queen Anne.** in Geography, a poll-town of America, in Prince George county, Maryland, situated on the W. side of Patuxent river, acros which is a wooden bridge. This small town is laid out on a regular plan, at the foot of a hill. It contains a few stores, and warehouses for the inspection of tobacco; 25 miles E.N.E. of Washington.

**Queen Anne's.** a county of Maryland, bounded W. by Chesapeak bay, and N. by Kent county; containing 16,654 inhabitants. Its chief town is Centerville. Belonging to this county is Kent island, 14 miles long from N. to S. and 6½ broad from E. to W. It is low, but the land is fertile, and its eastern side is bordered with salt marsh.

**Queen Catherine's Foreland,** the northernmost point of Terra del Fuego, at the exit entrance into the straits of Magellan, discovered by Frobisher in 1576.

**Queen Charlez's Foreland,** the S.E. extremity of New Caledonia. N. lat. 22° 15'; E. long. 167° 14'.—Also, the S.W. point of New Hanover, in the East Indian sea, so called in 1767 by Capt. Carteret. The land about it is remarkable for a number of little hummocks, or hills. S. lat. 2° 29'; E. long. 148° 27'.

**Queen Charlotte's Island,** an island in the Pacific ocean, about six miles long, and one broad, discovered in the year 1767, by captain Wallis. It is described as sandy and level, full of trees, without underwood, and abounding with fcurry-grafts. The caeskos of this island appeared to be about 30 feet long, 4 feet broad, and ½ deep. The inhabitants were of a middle stature, and dark complexion, with long black hair, hanging loose over their shoulders. The men were well made, and the women handfome. Their garments were of a kind of coarse matting, fastened about their middle, and capable of being brought round their shoulders. The men who landed saw no appearance of any kind of metal, but observed several tools made of shells and stones, sharpened and fitted into handles, like adzes, chisels, and awls. They saw few repertories of the dead, in which bodies were left to putrefy, under canopries, and not deposited in the ground. The island was taken possession of by captain Wallis and his crew, in the name of his Britannic majesty. They also left some hatchets, nails, glasses bottles, beads, shellings, sippers, and halfpence, as presents to the natives. S. lat. 10° 18'; W. long. 138° 4'.

**Queen Charlotte's Islands,** a group of islands, discovered in 1767 by Capt. Carteret, confuting of Egmont's island or New Guernsey, Lord Howel's island or New Jersey, and several others. A quarrel having occurred in consequence of the imprudent conduct of the master of Capt. Carteret's ship, between the crew and the natives, several of the latter were killed, and four of the former died in consequence of their wounds. This unfortunate event prevented any intercourse with the inhabitants of these islands. Egmont island, says Capt. Carteret, who called it by this name in honour of the earl, is the same with the Santa Cruz of the Spaniards; and the place in which the ship had lain he called Swallow bay; about ten miles W. from this bay is a small island, near the coast, called Portland's island; and to the bay farther west, where the ship's cutter had been attacked by the Indians, he gave the name of Bloody bay. In this bay is a small rivulet of fresh water, and here were seen many houfes, and near the water-side, one much longer than any of the rest, which seemed to be a kind of common hall, or council-houfe, and was neatly built and thatched. The sides and the floor of this edifice were covered with a kind of fine matting, and bundles of arrows were hung up in it ready for use. At this place there were also many fine gardens and plantations, inclosed by a fence of Rone, and planted with cocoa-nut trees, bananas, plantains, yams, and other vegetables. About three miles W. of this town was another of considerable extent, in the front of which, near the water, was a breadth-work of Rone, about four feet six inches high, angularly formed like a fortification; from which, and from other circumstancies, there is reason to believe that the natives have frequent wars among themselves. At the distance of two or three miles farther westward was found a small right, receiving a river, which was called Granville's river, and westward of it is a point, to which was given the name of Ferrar's point. From this point the land forms a large bay, near which is a town of great extent, and apparently very populous. About seven miles W. of Ferrar's point is another, that was called Carteret's point, from which a reef of rocks, that appears above water, runs out to the distance of about a cable's length. The W. of this was another large town, fronted like the last, and the people who thronged to the beach while the ship was passing, performed the same kind of circular dance with those of the former place. They were furnished with a number of canoes of different sizes. The inhabitants of Egmont island are extremely nimble, vigorous, and active, and seem as well qualified to live on the water as on the land, for they were in and out of their canoes almost every minute. With their bows and arrows they do execution at an incredible distance. Their arrows were pointed with flint, nor was there seen among them any appearance of metal. The country, in general, is woody and mountainous, intermixed with many valleys; several small rivers flow from the interior part of the country into the sea, and upon the coast there are many harbours. S. lat. 30° 50' to 11° 20'; E. long. 163° 30' to 165° 10'.

**Queen Charlotte's Sound.** See Queen Charlotte's Sound. Mr. Anderfon, who visited this country four times, has made the following remarks on the country near it. The land is every where uncommonly mountainous, rising immediately from the sea into large hills, with blunted tops. At considerable distances are valleys, or rather impression on the sides of the hills, which are not deep, each terminating towards the sea in a small cove, with a pebbly or sandy beach, behind which are small flats, where the natives generally build their huts, at the same time landing their canoes upon the beaches. The bases of these mountains, at least towards the shore, are confruted of a brittle, yellowish sand-stone, which requires a blueish cay, where the tea wafle that it runs into some places, in horizontal, and, at other places, in oblique frata; being frequently divided, at small distances, by thin veins of coarse quartz. The mould, or soil, which covers this, is of a yellowish colour, not unlike marble, and is commonly
monly from a foot to two or more in thicknesses. The quality of this soil is best indicated by the luxuriant growth of its productions: the hills being one continued forest of trees, owing the strength of their vegetation partly to the soil, and partly also to the agreeable temperature of the climate. In February, corresponding to our August, the thermometer was not higher than 66°; and in June, corresponding to our December, the mercury never fell lower than 48°.

The weather is, in general, good; but sometimes rainy, with heavy rain, which, however, never falls above a day; nor is it ever excessive. Among the trees, which covered the hills, and which are of two sorts, one supplied the place of spuce in making beer, for which purpose a strong decoction of its leaves was fermented with treacle or sugar. The other sort of tree resembled a maple, and its wood served for fuel. On the small flat spots behind there is a great variety of trees. Among other plants that were useful, may be reckoned the wild celery, which grows plentifully almost in every cove, and one that is called curry-grass, though very different from the plant to which we give that name. Both sorts were boiled every morning, with wheat ground in a mill, and with portable sauce for the people’s breakfast, and amongst their pea-foup for dinner. Sometimes they were used as salad, or dressed as greens. There is another plant, which produces a fine filky flax, of which the natives make their garments. A species of long pepper is also found in great plenty. The birds are almost entirely peculiar to the place. The principal fih caught with the feine were mullets and elephant-fish, with a few sole and flounders; but those of the natives mostly supplied were a fort of sea-bream, of a silver colour, with a black spot on the neck, large conger-eels, and a fih in shape like the bream, but so large as to weigh five, fix, or seven pounds, and called “Mogge” by the natives. Of all the sorts of fih, which are here numerous, the mogge, small salmon, and colour fih, as the feamen called it, though different from ours, are superior to the rest. The rocks furnish a great variety of shell-fish. Insects are very rare. In this extensive land there are not even traces of any quadruped, excepting only a few rats, and a fort of fox-dog, which is a domestic animal with the natives. Neither is there any mineral worth notice, but a green jasper or serpent-stone, of which the New Zealanders make their tools and ornaments.

The natives do not exceed the common stature of Europeans, and, in general, are not so well made. Their colour is of different casts, from a deep black to a yellowish or olive tinge; and their features are also various, some resembling Europeans. But in general their faces are round, with their lips full, and also their noses towards the point; though the first is not uncommonly thick, nor the last flat. Their teeth are generally broad, white, and well set; and their eyes large, with a very free motion, which seems the effect of habit; their hair is black, straight, and frizzed; commonly cut short on the hind part, with the raft tied on the crown of the head; but some have it curling, and of a brown colour. In the young, the countenance is generally free or open; but in many of the men it has a serious cast, and sometimes a fullness, or reserve, especially if they are strangers. The women are in general smaller than the men; but have few peculiar graces. The drefs of both sexes is alike; and consists of an oblong garment, about five feet long and four broad, and made of the filky flax before mentioned. This seems to be their most material and complex manufacture, and is executed by knotting; and their work is often ornamented with pieces of dog-skin, or chequered at the corners. They bring two corners of this garment over their shoulders, and fasten it on the breast, with the other part which covers the body; and about the belly it is again tied with a girdle made of mat. Sometimes they cover it with large feathers of birds, (which seem to be wrought into the piece of cloth when it is made,) or with dog-skin; and that alone sometimes worn as a covering. Over this garment many of them wear mats, which reach from their shoulders to their heels. But the most common outer covering is a quantity of fedge-plant, badly dressed, which they fall on a string to a considerable length, and throwing it about the shoulders, let it fall down on all sides, as far as the middle of the thighs. In way of ornament, they fix in their heads feathers, or combs of bone or wood, adorned with pearl-shell, or the thin inner skin of some leaf; and in the ears both of men and women, which are pierced, or rather slit, are hung small pieces of Jasper, bits of cloth, or beads, when they can get them. A few also have the septum of the nose bored in the lower part. They wear long beards, but are fond of having them shaved. Some are punctured or flained in the face, with curious spiral and other figures, of a black or deep blue colour; but it is doubtful whether this be ornamental, or intended as a mark of peculiar distinction; and the women who are marked so, have the puncture only on their lips, or a small spot on their chins. Both sexes often beautify their faces and heads with a red paint, which seems to be a martial ochre, mixed with grease; and the women sometimes wear necklaces of shark’s teeth, or bunches of long heads, which seem to be made of the leg-bones of small birds, or a particular shell. They live in small coves, in companies of forty or fifty, or more; and sometimes in single families, building their huts contiguous to each other; which are in general miserable lodging places. The belt was about thirty feet long, sixteen broad, and fix high; built exactly in the manner of an English barn. They seemed to have no other furniture than a few small baskets or bags, in which they put their fishing-hooks and other tripples. They live chiefly by fishing, making use either of nets of different kinds, or of wooden fish-books, pointed with bone; but so oddly made, that a stranger would be at a loss to know how they can fisher such a purpose. Their boats are well built of planks, raised upon each other, and fastened with string which, also bind a long narrow piece on the outside of the seams, to prevent their leaking. Some are fifty feet long, and so broad as to be able to fail without an outrigger; but the smaller boats commonly have one; and they often fallen two together by rafters, forming a double canoe. They carry from five to thirty men, or more; and often have a large head, ingeniously carved, and painted with a figure at the point, which seems intended to represent a man with his features distorted by rage. Their paddles are about four or five feet long, narrow, and pointed; with which, when they keep time, the boat is pushed along pretty swiftly. Their sails are carried on a high mast, raised on the end of a long pole, which is suspended to the middle of the boat. They are so well made of planks, that they can hardly be distinguished from a ship, and are often four or five men wide. They have sails and yards, with a mast, a lower and an upper, and the sails they have of coarse cloth. They are made of the same material, with which the boys are covered: they are so well made, that when they are taken, they can be furnished with no other covering than an overcoat or upper cloth, which is also made of the same material. It is a large square piece, which is made of a single piece of mat. Sometimes they make it with a girdle, which is again tied with a girdle, and the other part which covers the body; and about the belly it is again tied with a girdle made of mat.

1,300, Water, - 1,000, Bog, mountain, and, waste, - 21,000, Roads, - 2,000, 235,320, The, map, belonging, to, the, grand, jury, reckons, 244,938, acres, and, of, these, 60,000, bog, and, mountain, Almost, every, description, of, soil, is, found, in, this, county, and, it, varies, from, a, very, stiff, clay, to, a, sandy, loam, which, though, light, is, yet, fertile, a, strong, gravelly, soil, very, favourable, to, corn, is, also, prevalent, Lime-clay, is, common, that, there, are, rich, quarries, of, it, in, almost, every, townland, The, soil
QUE

foil of the Shieh-bloom mountains is variable, the surface inclining to a black and alternately yellow fluff clay, of unequal depths, covering a loam, rotten rock, or a gritty gravel, with occasionally a little appearance of lime-flone. The western side, more generally, inclines to a strong red clay, not unlike the nature of the soil in both of the northeastern counties in Ireland, where oats and potatoes only are found; but it is generally, throughout, freony, wet, and boggy to the summit, and very rocky. Through the whole of the county, except in the south-eastern corner, near Carlow, where the colleries are extensive, bog is well interpenetrated, and is the general fuel. The depth of these bogs is various, and in some parts undetermined, the belt of fuel lying in some few fides depth below the surface, in others very deep. The mosses are a shallow bog, with a stratum of gravel or clay, under one or two fides depth; this particular kind is easily reclaimed, and becomes the belt and fured land in the county, and the coal is here but trifling, indeed often repaid in one year, having all the materials within themselves.

Amongst the mineral productions of this county, for Charles Coote, the author of the Statistical Survey, enumerates "coal, iron, copper, manganese, mica, lime-flone, marble, free-flone, ochre, marble, fuller's-earth, and a great variety of clays valuable in every branch of pottery." Such an enumeration is of little use; being recommended neither by detail of facts and places, nor by accuracy of information. The coal district is in another part of the same work more fully noticed; but the reader who wishes for information, is more likely to find it in the report of Mr. Griffith, mining engineer of the Dublin Society, which is shortly to be published. The coal is of that description called flone coal, the glance-coal of Jamestown, and beet known by the name of Kilkeeny coal. The Queen's county colleries seem to have laboured under many disadvantages, from want of capital or of proper exertion; but a prospect is opening upon us of more attention to this source of wealth. There is a very small quantity of old timber in the Queen's county. There are, indeed, leaves still in existence, by which the tenant was obliged to cut, burn, or defray so many acres of wood, to clear the land for the plough; a system which, if necessary to the establishment of order in the county, was the cause of reducing it to the bare flate with respect to timber, with which the English traveller is so often struck. The Barrow and the Nore are the principal rivers which water this county. The latter is not navigable, though, being a fine deep and spacious river, it might be easily rendered so, by levelling the numerous weirs, that are of great detriment to the adjoining lands, and throw up a considerable quantity of back water.

The Barrow is navigable throughout from Portarlington, near which it beautifully expands and winds through extensive and fertile banks. There are no lakes which deserve notice. Maryborough is the county town, near which, as well as Mountmelich and Moonstrath, there was a considerable wooden manufacture of flutes, &c. which has declined. For any particulars respecting the towns, the reader is referred to the respective articles. Besides those mentioned, Portarlington is a place of some importance, and Stradbally a neat town. The county is represented in parliament by two knights of the shire, and by one member for the borough of Portarlington. Maryborough and Ballynekill were disfranchised at the union. Sir C. Coote's Statistical Survey. Beaufort's Memoir.

QUEEN's Creek, a river of America, in North Carolina, which runs into the Atlantic, N. lat. 34° 37'. W. long. 77° 28'.
It has been generally supposed, that the queen-bee is the only female contained in the hive; that the drones are the males by which she is fecundated; and that the working-bees are neutral, or of neither sex. But M. Schirach has lately established a different doctrine, which has been also confirmed by the later observations of Mr. Debray. According to this writer, all the working or common bees are females in disguise; and the queen-bee lays only two kinds of eggs, viz. those which are to produce the drones, and those from which the working-bees are to proceed; and from any one or more of these, one or more queens may be produced; so that every worm of the latter or common kind, which has been hatched about three days, is capable, under certain circumstances, of becoming the queen, or mother of a hive. In proof of this doctrine, new and singular as it may seem, he alleges a number of satisfactory and decisive experiments, which have been since verified by those of Mr. Debray. For the proof of this doctrine by Schirach and Debray, and the objections of Mr. Hunter, we refer to the article Generation of Bees.

From this doctrine we may justly infer, that the kingdom of the bees is not, if the expression may be used, a pure divine, or hereditary monarchy, but an elective kingdom, in which the choice of their future ruler is made by the body of the people, while she is yet in the cradle, or in embryo; and who are determined by motives of preference which will perhaps for ever obscure the penetration of the most sagacious naturalists.

The conclusions drawn by M. Schirach, from experiments of the preceding kind, very often repeated by himself and others with the same success, are, that all the common or working bees were originally of the female sex; but that when they have undergone their last metamorphosis, they are condemned to a state of perpetual virginity, and the organs of generation are obliterated; merely because they have not been lodged, fed, and brought up in a particular manner, while they were in the worm state. He supposes, that the worm designed by the community to be a queen, or mother, owes its metamorphosis into a queen, partly to the extraordinary fize of its cell, and its peculiar position in it; but principally to a certain appropriate nourishment found there and carefully administered to it by the working bees, while it was in the worm state; by which, and possibly other means unknown, the development and extension of the germ of the female organs, previously existing in the embryo, is effected; and those differences in its form and size are produced, which afterwards so remarkably distinguish it from the common working bees. Schirach's Histoire Nat. de la Reine des Abeilles, &c. 8vo. 1772. Or, for an abstract, Monthly Review, vol. xlviii. p. 564, &c. Phil. Trans. vol. lxxiii. part i. p. 29, &c. See Generation and Sex of Bees.

This discovery is capable of being applied towards forming artificial swarms, or new colonies of bees, by which means the number of these useful insects might be increased, and their produce in honey and wax proportionately augmented. M. Schirach, as well as M. Hallof, feem, however, to have been mistaken, when they affect, that the artificial queens, formed and reared in a community consisting only of working bees, proceed almost immediately to lay eggs, and to people the hive, without having had any communication with the drones, and that a time when, as they suppose, there were no drones in being. It is not necessary to advert the idea of the prolific quality of a virgin queen-bee; as nature has provided drones of different sizes, for the purpose of impregnating the eggs laid by the female, and continuing the species, adapted to different occasions and circumstances. See Drone.

Queen's Bench. See King's Bench, &c.
Queen's Gilliflower, or Violet, in Botany. See Hessicks.
Queen Gold, aurum regina, an annual royal revenue, belonging to the queen of England, during her marriage to the king: and payable by divers persons (upon several grants of the king) by way of oblation out of fines, amounting to ten marks, or upwards; viz. one full tenth part above the entire fine, or ten pounds for every hundred pounds fine, on pardons and contracts or agreements.

This becomes a real debt to the queen, by the name of aurum regina, upon the party's bare agreement with the king for a fine, and recording it without any further promise, or contract, for this tenth part extraordinary. Queen of the Meadows, in Botany. See Spiraea.
Queen's Ware. See Pottery.
Queen's Theatre in the Haymarket, now the Opera-House, was built in queen Anne's time by sir John Vanburgh, and not finished till the summer of 1705, at which time there were only two theatres open: Drury Lane, and Lincoln's-Inn-Fields. Betterton, who was at the head of the Lincoln's-Inn-Fields company, renewed to the new theatre in the Haymarket, April 9th, 1705; when it was opened with a new prologue, written by sir Samuel Garth, and spoken by Mrs. Bracegirdle. The play was Dryden's "Indian Emperor," with singing by the Italian boy. April 24th, "The Merry Wives of Windsor," Falstaff by Betterton, with dancing by Mad. de la Val, And on the 24th, a new farce called "The Confutation," after which was performed an Italian pantomime, called the "Loves of Ergaia," set to music by Giacomo Greber, the German musician, who had brought over from Italy Margarita de l'Epine; the part of Licoris by the Italian boy. And this was the first attempt at dramatic music in the Opera-House. The company continued acting plays here till the end of June, when there were three representations of "Love for Love," acted all by women. July 20th, according to the Daily Courant, Betterton and his company returned to the theatre in Lincoln's-Inn-Fields, where they continued to act till the Queen's theatre was entirely finished. We are the more minute about the performances in this theatre, as Cibber's account, which has been generally followed by others, is very inaccurate. October 30th, Betterton and his company quitted Lincoln's-Inn-Fields a second time, and returning to the Haymarket, opened that theatre, not with an opera, but with sir John Vanburgh's comedy of the "Confederacy," which was now acted for the first time. This excellent comedy, though the parts were very strongly cast (Leigh, Douglas, and Booth, being among the men, and Mrs. Barry, Mrs. Porter, and Mrs. Bracegirdle, among the women,) ran but six nights successively, though the performance of M. des Barques, a dancer just arrived from France, was added to the entertainment. It was, indeed, repeated once in November, and twice in December, this year; but it was generally found necessary, even in a new theatre, and with so strong a company, to fortify the bell plays with dances or music, and often with both. Sometimes there was singing in Italian and English, by Signor Maria, as lately taught by Signor N. Haym; and sometimes music composed by Signor Bonfini, and sung by Signor Loxceini, &c. See Daily Courant.

QUEENBOROUGH, in Geography, a borough and market-town in the liberty of the Isle of Sheppey, lathe of Seray, and county of Kent, England, is situated about three miles south from Sheerness, and forty-five miles by south from London. It was anciently called Cyningburgh, from belonging
longing to the Saxon kings, who had a castle here, near the western entrance of the Swale, which, after the conquest, was denominated the castle of Sheepe. This fortress being totally demolished in the reign of Edward III., that monarch commenced, in 1360, a more extensive and magnificent one, which was finished in the period of six years, under the superintendence of the celebrated William of Wykeham, afterwards bishop of Winchester. When the castle was completed, Edward came and resided in it several days, during which time he constituted the then village a free borough, and ordered it to be called Queenborough, in honour of his consort Philippa of Hainault. By the charter of incorporation, which bears date in 1366, he conferred fundy privileges upon the burgesses, and empowered them to elect a mayor, two bailiffs, four jurats, a town ferjeant, and a water bailiff, who were to take their oath of allegiance before the constable of the castle, and to act as judges of the peace within the liberty of the corporation. This charter was confirmed, with additional privileges, by king Charles I.

Queenborough consists chiefly of one street, which is very wide, and is formed mostly of modern buildings. According to the parliamentary returns of 1811, the borough, which coincides in extent with the parish, contains 163 houses and 825 inhabitants, who are principally fishermen and oyster dredgers. The market days are Monday and Thursday weekly, and there is a well-attended fair on the 5th of August. This town sends two members to parliament, who are elected by the mayor, jurats, bailiffs, and burgesses, about 150 in number, though by the last decision of the house of commons in 1729, the elective franchise was declared to reside only in the mayor, jurats, and common council. The mayor is the returning officer, and the patronage is in the admiralty and board of ordnance.

Of the castle built by king Edward, no traces remain except the moat by which it was surmounted, and a well, by which it was supplied with water, as the town still is. Though a large and massive structure, and erected, as the letters patent express it, "for the strength of the realm, and for the refuge of the inhabitants of this isle," it does not appear to have ever been of any particular use, at least it is never mentioned in history as having been befouled, or occupied as an important military post. It was nevertheless several times repaired; first by Richard II., and again in the time of Henry VIII. Queen Elizabeth also seems to have contributed to its preservation and embellishment, as her arms were displayed on the ceiling of the great hall, surrounded by those of the nobility, and principal gentry of the county, with the date 1593, affixed to some panegyrical verses in honour of that princess. The church here was originally built as a chapel to Minster, a village situated about two miles from the town, and deriving its name from the minster, or nunnery founded there by Sexburga, widow of Ercombert, king of Kent, about the year 673. That prince placed twenty-seven nuns in her new institution, and took upon herelf the office of abbess, which the afterwards regisued to her daughter Ermemilda, and retired to Ely, where her sister Etheldreda predeceded. During the incursions of the Danes, this nunnery was deferted and nearly destroied; but when they invasions ceased, it was again tenanted by a few nuns, and continued to exist, though in a very mean state, till the year 1130, when the buildings were re-edited by Corbel, archbishop of Canterbury, and filled with nuns of the order of St. Benedict. At the dissolution their number was limited to a prior and ten nuns, whose estates were estimated at 129l. 7s. 10d. annual rent. These, with the site of the suppressed monastery, were then granted to sir Thomas Cheyney, lord warden and treasurer of the household to king Henry VIII. Of the buildings, a gate-house, and part of the church, are the only remains. The latter consists of two aisles, a chancel, and a neat chapel, with the lower division of a square tower at the west end. In conformity with the date of its erection, some of the arches are semicircular in form, but most of them are in the early pointed style. In the south wall of the chancel, under a range of cinquefoil arches, is the effigy of a knight templar, said to repreented and commemorated Sir Robert de Shurland, lord of Shurland, who was created a knight banneret by Edward I., for his gallant conduct at the siege of Carlaverock, in Scotland. Behind the figure, towards the back of the recess, is the representation of a horse's head in the act of swimming, which has given rise to much enquiry among antiquaries, and to many fabulous and superstitious stories among the vulgar. On the pavement are several brasses of knights and their ladies; and under the arch separating the chancel from the chapel, is a gorgeous altar-tomb in honour of sir Thomas Cheyney, above-mentioned. Another altar-tomb, near it, bears the recumbent figure of a Spanish general, or admiral taken prisoner by sir Francis Drake, on the defeat of the "Invincible Armada." From an entry in the parish register, he appears to have died on board a ship at the Nore in 1591. Beauties of England and Wales, vol. vii. by E. W. Brayley.

QUEENSBRIDGE, a township of America, in Washington county, New York, bounded easterly by Westfield and Kingbury; 33 miles N.E. of Albany.

QUEENSFERRY, South, a royal burgh and sea-port town in the county of Linlithgow, Scotland, is situated on the southern shore of the Frith of Forth, at the distance of nine miles W.N.W. from Edinburgh, on the great road to the north. It is first mentioned in the charters of king Malcolm IV. by the designation of "Passagium Regine," and is generally supposed from the frequent use of the ferry here by his great grandmother Margaret, queen to Malcolm Canmore, a princess highly celebrated in Scotch history for her charitable and benevolent qualities. At that period, however, it was only a village and port, endowed with some trading privileges; indeed, its constitution as a royal burgh did not take place till about the year 1556, when its elevation to that rank was rcemionly opposed by the corporation of Linlithgow. It is now governed by a provost, one land bailiff, two sea bailiffs, a dean of guild, and a town council, who, like most other counsellors in royal burghs, are self-elected. Formerly this port enjoyed a considerable trade, and even so late as the year 1642, it was frequented by above twenty ships belonging to resident owners; but its trade is at present confined to the importation of coal, for the consumption of the inhabitants, and of the materials used in the manufacture of brown paper, which, with the fishery and the business of the ferry, constitute the chief support of the town. The harbour is in good repair, and is frequently referred to as a place of retreat in hard gales, by the smaller vessels navigating the Forth. The passage here does not exceed two miles in breadth, and, except in very boisterous weather, may be crossed at all times with safety and expedition. Much obscurity prevails relative to the founding of this ferry. The right of it is private property, and seems originally to have been attached to the lands of Murie Hall, which lie in the vicinity of the town, and are traditionally said to have been appropriated for "upholding the passage." The present proprietors are several gentlemen poling off land on either side of the Forth, who let the passage yearly by public auction. As all the northern mails, and most carriages travellers, pass at this ferry, the intercourse between its shores is constant and regular. Cattle also are transported...
ported over in great numbers, as well as carts and waggons; but the difficulty and danger of effecting these objects, have induced cattle-drivers and carriers to go round by the bridge at Stirling.

The parih of Queensberry is of small extent, being confined entirely to the royalty. In ecclesiastical matters it forms part of the provostery of Linlithgow, and synod of Lothian and Tweedale; and, according to the population returns of 1811, contains 77 houses and 558 inhabitants.

On the summit of the ridge rising from the shore here, stands Hopetoun-houfe, the seat of the earl of Hopetoun, which is perhaps equal in magnificence of aspect to any palace or residence in Great Britain. The mansion is seated on a noble lawn, forming a kind of terrace along the Firth for more than a mile in front, and only terminated by the Frith, which winds round it, and appears like a wide and extensive lake, interspersed with islands and enlivened with a variety of shipping. Behind the house the ground is more extensive, breaking into hills, valleys, and promontories, which shoot into the Firth. All the grounds, to a considerable distance, are planted and adorned; and the house is judiciously flanked with a thick wood, to protect it against the violence of the northern winds. On this side the Firth affummes, at different points, different appearances, sometimes putting on the semblance of a lake, and sometimes that of a river. The house is a very noble display of architectural magnificence. It was begun by the celebrated architect Sir William Bruce, and finished by Mr. Adam, who is believed to have added the wings. It is much to be regretted, that the interior of this princely mansion does not correspond with the grand style of the exterior, in the fize and decorations of the apartments. Beauties of Scotland by Robert Forsyth, vol. iii. Carlile's Topographical Dictionary of Scotland, 4to. 1813.

Queensberry, North, a small sea-port town in the district and parish of Dunfermline, Scotland, is situated on the northern shore of the Firth of Firth, opposite to the royal burgh of South Queensberry, described in the preceding article. The principal export is whin-dore for paving, which is found in vast abundance in the extensive "whin-dore quarries" adjoining. Of that material a large proportion is conveyed to London, and many towns on the eastern coast of England. A hamlet, called St. Margaret, between this village and the head-land, which forms the western boundary of Inverkithing bay, is noted as the landing place of prince Edgar Atheling, and his sister Margaret, afterwards queen of Scotland, when they fled from England to avoid the effects of the conqueror's jealousy of Edgar's claim to the English crown. By an act of parliament, lately passed, the ferry has been placed under excellent regulations; and the harbour on each side, but particularly on the north side, has been much enlarged and improved. A signal house here contains apartments for the accommodation of the truflers, the superintendent, and boatmen.

Carlile's Topographical Dictionary of Scotland, 4to. 1813.

Queen's-Hope, or East-Hope, a town in the parish of Elgin, or Hope, county of Nairn, now called the hundred of Mold, and county of Flint, North Wales, is situated near the river Alun, at the distance of six miles N.W. from Wrexham. Together with the adjoining castle and hamlet of Caer-Gwydyr, it constiutes a burgh, both by prescription, and in virtue of a charter granted by Edward the Black Prince in 1351. That deed orders that the constable of the castle shall be mayor, ex officio, and shall nominate two bailiffs, to govern under him, from among the burgesses. This place obtained the appellation of Queen's-Hope, after the year 1281, from the circumstance of its having been then bestowed by Edward I. on his beloved and heroic consort Eleanor; or, as some affirm, from her majesty having lodged here, when on her way to Caernarvon to give the Welsh a ruler born within their own territories. The etymology of its ancient name, "Caergwydyr," (the camp of the gigantic legion,) seems to indicate that it was once occupied by the Romans; and in confirmation of this conjecture we may observe, that a Roman hypocaust has lately been discovered here, some of the tiles used in the construction of which were inscribed "Legio XX." Pennant supposes that it was an outpost to the grand station Deva, and notices the remains of two roads. The ruins of the castle of Caerwelry are seated on a lofty rock isolated from the surrounding land, and, on one side, extremely precipitous. At what time, or by whom it was originally built, is unknown; but in the reign of Owen Gwynedd, it formed part of the possessions of a chieftain named Gryfydd Maedor. Edward I. made a grant of it to prince David, and afterwards, as above-mentioned, to queen Eleanor, at whose death both castle and manor were given to John de Cromwell, on condition that he repaired the former, which had been late, and relatively damaged, as was supposedly by design, while the king and queen were resident in it. All that remains of this once magnificent fort are a circular tower, and a few fragments of walls, together with the deep foile, by which it was defended. This foile is excavated from the solid rock, which is composed of breccia, or an extensively coarse grit.

The conjoint borough of Queen's-Hope and Caerwelry, is contributory with the town of Flint in the election of a representative to the British parliament. It formerly had the privileges of a market and fairs, but these are now discontinued. The parish is divided into two districts, called Hope and Kinerton, and contains, according to the parliamentary returns of 1811, 547 houses and 2617 inhabitants. Of these a large proportion reside in the town, which consists of three broad parallel streets, intersected at right angles by three others of less breadth, the whole placed on the side of a rising ground, gently sloping to the river. The principal building is the church, which contains two mural monuments, one decorated with kneeling figures, but without any inscription; and the other commemorating Sir John Trevor, knt. secretary to the earl of Nottingham, the conqueror of the boated invincible armada.

Some objects in the vicinity of the place claim notice. On a hill, opposite to that of Caerwelry, is the British encampment of Caer-Eilyn, which is formed by a single ditch and rampart. The adjacent summits consist chiefly of lime-stone, and display on their surface numerous organic examples of the fossil remains called entrochi and allroites. The uncommon species of the latter, usually denominated the arborescent fa-dlar, has been found here. At Rhuddyn are two springs strongly impregnated with muriate of soda, the waters of which are found highly serviceable in such chronic disorders as elephantias and scrofula. At this place is a fine old bridge over the river Alun. On the road to Wrexham, about two miles from Queen's-Hope, is Plas-Teg, the seat of the Trevor family. The house is a very noble building, and is generally believed to have been the work of Inigo Jones. Beyond this is Harts-Heath Hall, the property of Guilvin Lloyd Wardle, esq. It is a large modern mansion, forming a square, with three fronts, and is surrounded by fine plantations. Carlile's Topographical Dictionary of Wales, 4to. 1812. Pennant's Tour in Wales.
QUEENSTADT, a town of Weilphalia, in the principality of Halberstadt; three miles N.E. of Halberstadt.

QUEENSTOWN, a post-town of America, in Queen Anne's county, Maryland, on the E. side of Chester river; six miles S.W. of Centerville, and 65 from Washington.

QUEENSTOWN, a town or village of Upper Canada, which lies on the W. side of the tributaries of Niagara, near Fort Niagara, and seven miles below the Falls. It is at the head of navigation for ships; and the portage occasioned by the Falls of Niagara commences here. From the sudden change in the face of the country in the neighbourhood of Queenstown, and the equally sudden change in the river with respect to its breadth, depth, and current, it has been conjectured, that the great falls of the river must originally have been situated at the spot where the waves are so abruptly contracted between the hills; and moreover it is a fact well ascertained, that the falls have receded very considerably since they were first visited by Europeans, and that they are still receding every year. See Weld's Travels, vol. ii. p. 130.

QUEE SAN ISLANDS. See CHUSAN.

QUE ESTATE, in Law, a plea whereby a man entitling himself to land, &c. faith, that the same estate which another had, he now has from him. Thus, e. g. the plaintiff alleges that such four persons were seized of lands whereunto the adwifon in queston belonged in fee, and that afterwards the church was vacant; que est eftate, i.e. which estate he now has; and, by virtue thereof, he pleads, &c. See PRESCRIPTION.

QUE EST MEME, a term used in actions of trespass, &c. for a direct justification of the very act complained of by the plaintiff as a wrong. Thus, in an action upon the cape, the plaintiff saying the lord threatened his tenants at will in such fort, as he forced them to give up their lands; the lord in his defence pleads, that he said them if they would not depart, he would sue them at law. Que est meme, i.e. this being the same threatening that he used, the defence is good.

QUEGASCA HARBOUR, in Geography, a bay on the S. coast of Labrador. N. lat. 50° 0'. W. long. 61° 22'.

QUEI, in Natural History, a name given by the Chinese to a peculiar earth found in many parts of the East. It is of the nature of an indurated clay, and in some degree approaches to the ashes, as the lattices and the galletites do. It is very white and abractive, used by the women of China, to take off spots from the skin, and render it soft and smooth, as the Italian ladies use table of Venice. They sometimes use the fine powder of this flour dry, rubbing it on the hands and face after washing; sometimes they mix it with pomatum.

QUEIC, in Geography, a river of France, which passes by Landau, and runs into the Rhine, near Germersheim.

QUEICHUN, a city of China, of the second rank, in the province of Quang-fu. N. lat. 23° 22'. E. long. 106° 44'.

QUEIGE, a town of France, in the department of Mont Blanc; four miles N.E. of Conflans.

QUEIGN, a town of Africa, in the kingdom of Bambouk.

QUEILING, a city of China, and capital of the province of Quang-fu, derives its name from a flower called "quei," which grows on a tree resembling a laurel; it exudes to favet and agreeable an odour, that the whole country around is perfumed with it. This city is situated on the banks of a river, which throws itself into the Ta-ho; but it flows with such rapidity, that it is neither navigable nor of any utility to commerce. Quei-ling is a large city, and the whole of it is built almost after the model of our ancient fortresses; but it is much inferior to most of the capitals of the other provinces. Birds are found in great numbers in the territories belonging to it, the colours of which are so bright and variegated, that the art of this country, in order to give additional lustre to their filks, interweave with them some of their feathers, which have a splendour and beauty that cannot be imitated. Quei-ling has under its jurisdiction two cities of the second class, and seven of the third. N. lat. 25° 12'. E. long. 109° 51'.

QUEIOS, a river of Spain, in Navarre, which runs into the Ebro, near Tudella.

QUEIRA, a town of Africa, in Ludamur; eight miles S. of Benomun.

QUEI, a river of Silecia, which rises in the principality of Jauer, pales by Friedberg, Grieffenberg, &c. and joins the Doher, between Sprietau and Sagan.

QUEI-TE, a city of China, of the second rank, in Quang-fu. N. lat. 23° 18'. E. long. 107° 4'.

QUEILAINES, a town of France, in the department of the Mayenne; eight miles S. of Laval.

QUELEA, in Ornithology, a species of Emberiza; which feeds on the flowers of grasses.

QUELINES, in Geography, mountains of Mexico, between the provinces of Guazaca and Chiapa.

QUELLINUS, ERASMUS, in Biography, called the Old, born at Antwerp in 1607, was a pupil of Rubens, and became a painter of history of very considerable reputation. He lived to the age of 71, and left a son John Erasmus Quellinus, who also became a painter, but who left the Flemish for the Venetian style of art, which he practised at Antwerp, his native city, till he arrived at the advanced age of 85, having been born in 1530.

QUELPARET, in Geography, an island in the sea of Corea, on which a Dutch vessel, called the Sparrow-hawk, was wrecked in the year 1655, then subject to the king of Corea. No island presents a finer aspect; the middle of the island is occupied by a peak of about 800 toises, visible at the distance of about 20 or 20 leagues, and she lans gradually slopes towards the sea, so that the inhabitants resemble an amphitheatre. The soil to a great height seems to be well cultivated. It belongs, however, to a people who are forbidden to hold any intercourse with strangers, and who detain in slavery unfortunate persons who are wrecked on the coasts. Some Dutchmen of the Sparrow-hawk, after a captivity of eighteen years, during which they received many bannides, found means to take away a bark, and to escape to Japan, from which they arrived at Batavia. N. lat. of the south point 33° 14'. E. long. 126° 35'.

QUELUSIA, in Botany, a name given by Vandelli to the beautiful Fuchsia coccinea, now so common in gardens. The author supposed it a new genus, and meant this to honour a royal villa near Lisbon, called Queius, where the first saw this plant in blossom.

QUEM reditum, reditum, in Law, an old writ which lay where a rent-chargé, or other rent, which was not servifee, was granted by fine holding of the grantor. If the tenant would not attorn, then the grantee might have had this writ.

QUEMARY, in Geography, a town of Bootan; 20 miles E. of Beyhar.

QUEMENES, a small island in the English channel, near the coast of France. N. lat. 48° 22'. W. long. 4° 48'.

QUEMI.
QUEMI, in Botany, a name used by some authors for the nigella, or geth.

QUEMIGNY, in Geography, a town of France, in the department of the Côte d'Or; nine miles S.W. of Dijon.

QUENDAL BAY, a bay at the S. extremity of the island of Shetland. N. lat. 59° 49'. W. long. 1° 40'.

QUENDON Water-Barrow, in Rural Economy, a contrivance of the barnow kind, much employed in the neighborhood of the little village of Quendon, in Essex, and from which it takes its name, for the purpose of conveying water, wash, and other liquid matters, to live flock of different kinds, as fattening cattle, logs, horses, and other animals, as well as for some other uses. It is a simple and excellent invention for all such intentions, as very great facility is given to its motion by means of the wheels, and it is, on the whole, very compact in its general formation, which gives it a superiority over many other contrivances of a similar nature, as being capable of being put in motion, when full, without any great difficulty, or the application of any extraordinary power or force.

It is represented at figs. 6 and 7, in Plate Agriculture, shewing the methods of clearing quarries, pits, &c., from water. Fig. 6. explains the plan, in which a, b, a, b, are the wheels, that rest on to the side-beams c, d, c, d, which are about four feet in length, and have their ends c, c, formed in such a manner as to serve for handles. E is an oval tub about thirty inches in depth, twenty-four in length, and eighteen in breadth, which is supported on the beams by two gudgeons, which play in semicircular boxes fixed near the ends of the beams; a crofs piece connects the two beams at f, f, as does another at g, g, to which two little curved pieces come, parallel to the form of the tub. The wheels are about four feet in height, and carry the tub suspended between them; for the gudgeons play almost over the two short axles, which fquare into the beams. Two flight legs are fixed underneath the barrow at ii, to keep it in an upright position, but they are not at all essential, for the tub would remain in a flata of equipoife between the wheels even without such aid. It must be noticed, that the tub is sunk rather more than one-half below the gudgeons. Fig. 7. represents the profile of the vehicle; the dotted line PENCL the fize and place of the tub, which is made oval, for the purpose of confining the breadth between the wheels, so as to pass in at narrow door-ways, &c.

It is probable that it might be somewhat improved by having the axles hooked within, so as to bear upon two loops in one of the iron hoops, and by this means render the use of gudgeons and boxes wholly unnecessary. The tub would lift off and on, as easily as at present, while it would hang in a more perfect and perfectly centrical manner. And still further, it would be a great convenience, if the upper part of the tub were furnished with a proper fpout in the front, in order to pour water or other liquid materials through between the pales, &c. for the supplying of cattle, &c. This would be more easily accomplished, if the tub were allowed to swing in a free manner, as it might in that cafe be tilted up with great facility, so as to favour its being done, as shown by the dotted line in fig. 2. About the little town noticed above, it is a great deal employed in carrying water for house use as well as that of farms. It is described in the Agricultural Magazine. Many other forms of water-barrows are made use of in different places. See Water-Barrow.

QUENEG, or QUENENA, in Geography, a district of Africa, in the country of Sughumella, near mount Atlas.

QUENOY, Le, a town of France, in the department of the North; five miles N.N.W. of Lille.

QUEentina, in Commerce, a small weight used in Germany; the ounce contains two lochs, or eight quentin.

QUENTIN, St., in Geography. See St. Quentin.

QUEPO, a town of Mexico, in the province of Costa Rica, on the Ebrilla; 70 miles S.W. of Cartagena.

QUERA, a town of Italy, in the Tuscany; 15 miles W. of Ceneda.

QUERALOS, a town of Spain, in Catalunia; 24 miles E. of Urgel.

QUERCERA, in Medicines. See Euphros.

QUERCETO, in Geography, a town of Lutria; nine miles S.W. of Volterra.

QUERCUS, in Botany, the Oak, an ancient Latin name, whose etymology has been considered as very uncertain, if not quite inexplicable. So it will well seem to those who looked no further than the Greek or Latin languages; for though some have deduced the word from θεος, a pig, because pigs feed on acorns, this explanation has not proved satisfactory. De Theis, on the authority of Lepeltier, has found a much better etymology for Quercus, in the Celtic querc, fine, and cuev, a tree; and this appellation is supposed to have been appropriated to the oak, not only for the beauty of the tree, but because it bore the sacred plant, mifeiito. This tree was also called in the Celtic tongue dero, whence came the word druid, or priest, of the oak, and even the Greek δρυς, an oak, vulgarly supposed the original of druid. (See Druids).—Linn. Gen. 495. Schreb. 464. Wild. Sp. Pl. v. 4. 423. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1278. Ait. Hort. Kew. v. 5. 287. Troum. t. 349. Lamarr. Illustr. t. 779. Gar. t. 37. (Cap. Tourn. t. 350. Super.)—Claw and order, Monoea Polyandria. Nat. Ord. Amentees. Linn. Jull.

Gen. Ch. Male, in a loose catkin. Cal. Perianth of one leaf, bell-shaped, membraneous, with about five small, sharp, often cloven segments. Cor. none. Stam. Filaments from four to ten, capillary, flat; anthers large, of two round lobes.

Female, from a bud usually on the same tree. Cal. Perianth of one leaf, inferior, coriaceous, hemispherical, rough, entire, very small in the flower, permanent. Cor. none. Pç. Germ similar, ovate, very small; style simple, divided above into two to five segments, longer than the calyx: stigma simple, permanent. Perc. none. Seed an oval or roundish coriaceous nut, of one valve, smooth, attached by its scarred base to the bottom of the stamens, hardened, permanent, cup-like calyx.

Female, Calyx bell-shaped, coriaceous, entire, rough. Corolla none. Style one. Stigmas from two to five. Nut coriaceous, embraced at the base by the hardened calyx.

This genus, so distinguished in its botanical characters, and valuable for its economical uses, confounds, in the Species Plantarum of Linnaeus, of no more than thirteen species. The discoveries of Thunberg, but especially those of American travellers, aided by the more accurate enquiries of botanists, have to greatly enriched the subject, that Wildenow, who has studied it well, enumerates twenty-six kinds of Quercus, and even these are not all that we have to describe. The importance of many species requires that they should all be particularized. Two or three of the East Indian ones, now for the first time described, offer some exceptions to the general character of the calyx.

Section 1. — Adult leaves undivided and entire
in Abbot's Infects of Georgia, v. 2. 181. t. 91. Michaux Querc. n. 7. t. 12. (Q. virginiana, f. longifol., folio, fructu tumido; Plunk. Amath. 180. t. 44. f. 7.)—Leaves membranaceous, linear-lanceolate, tapering at each end, entire, smooth, with a small point. Nut roundish.—Native of North America; in low swampy forests, near the sea-coast, from New Jersey to Florida, flowering in May. Pursh. It is said by Mr. Aiton, on the authority of Knowlton's M.S., to have been cultivated in England by Mr. Fairchild, before the year 1725; and indeed, by the collection at Dul- flore, this tree appears to have been planted there much earlier, among those introduced by the first earl of Portland. It ripens in its native country, as well as in England, to the height of fifty or sixty feet. The bark is smooth; the wood is good, and much in use, but of slow growth. Leaves scattered, on short flanks, four or five inches long, and not an inch wide, smooth, thin and plant, of a fine green, with a willow-like aspect, deciduous, their edges slightly wavy. Acorns in pairs, roundish, scarcely above an inch in length, with a thin, tuberculated, or tesselolated cup. The leaves of the young plant are somewhat angular, or toothed at each side. There is said to be a dwarf straggling variety, with shorter leaves, which Cateby has figured in his vol. 1. t. 22. Michaux has two supposed varieties, which other botanists esteem distinct species; see the following. The specific name, chosen by Linnaeus, is not a good one, oaks being the cork-tree.

2. Q. maritima. Ever-green Willow-leaved Oak. Willd. n. 2. Pursh n. 2. (Q. Phellos maritima; Michaux Querc. n. 7. var. 2. t. 13. f. 3.)—Leaves coriaceous, elliptic-lan- cecolate, entire, smooth, with a small point. Nut roundish.

—Found on the sea-coast of Virginia and Carolina, flowering in May and June. This differs from the foregoing in its low shrubby habit, and firm evergreen leaves, which are more elliptical in shape, and not above two inches long. The whole plant is from three to eight feet only in height. It appears by the accounts of authors to be distinct from the above-mentioned variety of Phellos.

3. Q. ferifca. Silky Willow-leaved Oak. Willd. n. 3. Pursh n. 3. (Q. Phellos; Sm. in Abb. Inf. v. 2. 101. t. 51. Q. Phellos pulita; Michaux Querc. n. 7. var. 3. t. 13. f. 1. 2.)—Leaves lanceolate-oblong, somewhat wavy; ob- tute at the base; rather dilated upwards; silky beneath. Nut almost globular.—Native of the sea-coast, from Caro- lina to Florida, flowering in May. It is perhaps the most humble of the whole genus, scarcely ever exceeding two feet in height, and throwing up creeping feynons, whence it has obtained the name of the Running Oak. The filikens of the leaves beneath gives them a glaucous appearance.

4. Q. myrtifolia. Myrtle-leaved Oak. Willd. n. 4. Pursh n. 4.—"Leaves coriaceous, oblong, entire, smooth, acute at each end."—Native of Carolina, according to Will- denow, who alone has noticed this species, and from whom Pursh has admitted it into his work. The branches are round, brown. Leaves an inch, or rather more, in length, cori- ceous, evergreen, oblong, somewhat acute at the base; en- tire and slightly revolute at the margin; shining above; opaque, but smooth, beneath; on short footstalks. The form of the leaves is much like the common broad-leaved myrtle. The flowers and fruit are unknown. Willd.

foi of sand upon clay, from Virginia to Florida and Missi- sippi, flowering in May. Miller cultivated it at Chelsea in 1739, but we know not that this species is still preferred, or, at least, distinguished from Q. Ilex, in our gardens or planta- tions. It is one of the most valuable American trees, growing to the height of forty or fifty feet, and extending its branches, in open situations, to a great extent; whence it serves, by its dense evergreen leaves, to shelter cattle from the simmer's heat and winter's cold. The wood is the finest and most durable ship timber. It is fetched towards the end of autumn, and kept three months before it is used. Michaux recommends this tree to the notice of the French and Spaniards, as likely to thrive well on the sandy coasts of the Mediterranean, and of the western ocean. By his account it succeeds best where there is a half of clay under the sand, to fix the larger roots. The aspect of the leaves is not unlike our European Q. Ilex, but they are, except when very young, more uniformly entire, and more fleshy; their under side less densely pubescent; and their short footstalks, as well as the mid-rib, reddish. The foliage of feeding plants, and of vigorous young shoots, is, indeed, strongly toothed. The adult leaves are scarcely more than two inches long, somewhat oval, or obovate and blunter, without any terminal bristle; silky in the spring; subsequently of a dark but shining green, and downy, with flary pubescence, beneath. The flaves are but four or five. Stalks of the fruit an inch long. Acorns cylindrical, an inch long, with a tessel- lated, but not roughed or tuberculated, cup. The acorns are said to be greedily devoured by hogs, and several wild animals; and to afford an oil, which the fages of Florida mix with their food.

6. Q. cinerca. Ash-coloured Silky-leaved Oak. Willd. n. 6. Ait. n. 3. Pursh n. 6. Michaux Querc. n. 8. t. 14. (Q. humilis; Walt. Carol. 234. Q. Phellos &; Linn. Sp. 1412.)—Leaves coriaceous, elliptic-lanceolate, re- volute, entire, blunter with a small point; clothed with flary down beneath. Fruit fleshy. Nut nearly globo- be.—Native of dry barren situations, and pine forests, from Vir- gina to Georgia, flowering in May. Michaux says it springs up chiefly on land that, after having been cultivated, be- comes abandoned on account of the bad quality of the soil. The form of the tree is unfigurably, and its size very variable, from four to twenty feet in height. The wood is of no use but for furing. Leaves longer than in the preceding; the young ones dilated at the top, with three points. Fruit nearly or quite fleshy, and not much more half an inch long.

7. Q. microphylla. Small-leaved Dwarf Oak. Willd. n. 7. Nee in Ann. Sci. Nat. v. 3. 264. Fitch. Misc. Hinf. v. 1. 99. Willd.—Leaves lanceolate, pointed, en- tire, villous; downy beneath. Calyx of the fruit villous. Nut roundish.—Found by Louis Neis, on the hills of Araharno, in New Spain. A frans, from three to five feet high, with a rough as-coloured bark. Leaves on short flanks, scattered, numerous, from four to six lines long, scarcely two lines broad, very, revolute, wavy, pointed, reddish-grey; villous above; downy beneath; tief the extremities of the branches opposite. Stipulas arched, falling off at the close of summer. Acorns in axillary pairs, about the ends of the branches, ovate, the size of a large pea, half covered by the villous cup, which is inveted with unequal scales. Nee.

long."—Found by Lewis Nee, in the kingdom of Mexico, near Acapulco. A tree twenty-eight feet high, with alternate branches; the young ones somewhat furrowed, and clothed with brownish-red hairs. Leaves from five to seven inches long, an inch wide, scattered, on short flanks, rather coriaceous, smooth, veiny, entire, wavy, pointed; reticulated and green above; yellowish beneath, with tufts of hairs, as big as a pin's head, in the forks of the veins. Acorns nearly felise, in axillary pairs, the size of a hazelnut, downy, half covered by the hemispherical, greyish, villous cup, befit with very thin scales. 

9. Q. glabra. Smooth-leaved Japan Oak. Thumb. Jap. 175. Willd. n. 9.—"Leaves lanceolate-oblong, pointed, smooth, with parallel veins."—Gathered by Thunberg in Japan. A tree, whose branches grow two or three together, slightly spreading, rugged and knotty. Leaves alternate, flaked, lanceolate-oblong, entire, pointed, with parallel ribs (veins); tapering at the base; smooth on both sides; shining above, yellowish beneath. Spikes of flowers either solitary, or two or three together, downy. Thunberg.

10. Q. centuncrs. Concentric-furrowed Oak. Laourin. Cochinch. 572. Willd. n. 10.—"Leaves lanceolate-oblate, pointed, incurved, entire. Calyx lax, very short, furrowed concentrically."—Native of the lofty forests of Cochinchina. A large tree, whose wood is serviceable for various uses. Branches ascending. Leaves scattered, flaked, smooth on both sides. Acorns flaked, oblong-ovate, smooth, red, pointed, their cups short and lax, externally marked with five parallel circular furrows; see n. 27.

11. Q. molueca. Molueca Oak. Linn. Sp. Pl. 1412. Willd. n. 11. Rumph. Ambom. v. 3. 85. t. 56.—Leaves elliptic-lanceolate, entire, acute at each end, smooth. Nut roundish, furrowed.—Native of the Molucca Isles. A large and lofty tree, whose wood is hard and heavy, lasting long under water. Leaves six or eight inches long and three broad, on short flanks, with eight or ten irregular lateral veins. Acorns short and roundish, furrowed in their upper part; the cup short, warty. By Rumphius's account, there seem to be more species than one comprehended under the chapter above cited, but he does not give us sufficient marks to define them distinctly.

12. Q. spiapa. Chatter-fruited Oak.—Leaves elliptic-lanceolate, taper-pointed, entire, smooth. Spikes axillary, solitary, dioecious. Fruit spikéd, aggregate, ovate. Gathered by Dr. Francis Buchanan, in woods at Suamba, in Upper N'paul, flowering in May, 1802. This is a tree of a vast dimension, whose wood is useful, though inferior in quality to that of Q. annulata, n. 22. The younger branches are angular, clothed with very minute green pubescence. Leaves alternate, flaked, of a broad lanceolate, or elliptical figure, with a taper point, entire throughout, six or seven inches long, and two and a half wide; bright green, smooth and shining above; paler, opaque, but scarcely pubescent, beneath; furnished with numerous, parallel, transverse veins. Footflanks not an inch long, depressed. Stipula deciduous. Flowers in long, linear, downy, pale, fragrant, solitary, axillary spikes; the male with about eight flaments, much longer than the calyx, and a roundish rudiment of a germ in the centre; females on a separate tree, crowded three together in forked groups in each spike. Acorns edible, but not very good, the size and shape of a large filbert, even, pointed, dark brown; the cup short, feathery. The original natives of Nepaul, or Nawars, know this tree by the name of Guyu Sufri, or Pacywhingah: their Hindu conquerors, the Parbutties, call it Arcula.

13. Q. tribuloides. Caltrorn-fruited Oak.—Leaves ovato-lanceolate, taper-pointed, entire, smooth. Spikes aggregate. Calyx of the fruit spiny, covering the nut.—Diff. covered by the fable botanist as the preceding, in the forests of Upper Nepaul, flowering and fruiting at various feasons. A tree with smooth branches. Leaves on short flanks, lanceolate, more or less ovate, somewhat unequal at the base, about four inches long, and one and a half broad, rigid and rather coriaceous, with irregular, distant, slightly curved veins; the upper surface polished; the under paler and opaque. Flowers monoeocious, in slender, downy, clustered, axillary or terminal, pendulous spikes, the male spikéd most numerous. Stamens about eight, with a dotted central disk. Acorns spikéd, scattered, ovate, smooth, obliquely pointed, about half an inch long, entirely concealed in the greatly enlarged calyx, which is downy, globose, and armed with very numerous, rigid, prominent, sharp thorns, a quarter of an inch, or more, in length, spreading in every direction. This species is called Cattam, or Curtongus, in the Parbutty language; Shingali, or Catu Shingali, by the Nawars. Its great peculiarity consists in the acorns, which are edible, being entirely enclosed in a strongly muricate calyx, or globose cup, which approaches the nature of the chefnut, Fagus Caffamce, and in some of our specimens seems even to split into two or three valves. The flowers, however, agree with Quercus, to which genus Dr. Buchanan referred this remarkable plant. On one tree he observed the flowers to be all female.

14. Q. laurifolia. Laurel-leaved Oak. Willd. n. 12. Art. n. 4. Pursh n. 8. Michaux Querc. n. 10. t. 17. 18.—Leaves ovate, entire, smooth, nearly felise; tapering at the base. Nut roundish, even. —Native of shady forests, and the sea-coast, in Georgia and South Carolina, flowering in May. This is sometimes called the Swamp Willow, and was first brought alive to England, by the late Mr. Fraer, 1786. It rises to the height of fifty or sixty feet. Michaux speaks of the wood as of a good quality, but inferior on the whole to that of our fifth species, Q. virgins. The leaves are crowded about the ends of the branches, deciduous, about four inches long, usually acute, but sometimes, as in Michaux's t. 18, remarkably obtuse. Acorns solitary, nearly felise, almost globose, with a feacy cup.

15. Q. imbricaria. Shingle Oak. Willd. n. 13. Art. n. 5. Pursh n. 7. Michaux Querc. n. 9. t. 15. 16.—Leaves elliptic-oblong, acute at each end, entire, almost felise; downy beneath. Nut nearly globose. —Native of the banks of rivers among the Alleghany mountains, and in the countries to the west, rarely to the east of those mountains, flowering in May and June. Brought to England in 1786, by Mr. Fraer. The leaves are twice the fise of the last, acute, but not contracted, at their base, and downy on the under side. Acorns much like the last-described. This tree is forty or fifty feet high. Its wood is chiefly used by the French settlers in the Illinois country, for making boards to cover houses, whence the appellation of Q. imbricaria in Michaux, and of Shingle Oak among the English Americans. For although the fies of the cup are rather larger than those of Q. laurifolia, the specific name does not allude to that circumstance.

16. Q. eItripes. Oval-leaved Mexican Oak. [Willd.] n. 14. Reec in Annul. Scient. Nat. v. 3. 278. Fifich. Mifs. Hftp. v. 1. 117.—"Leaves elliptical, entire, coriaceous, nearly felise; rounded at each end; roughish beneath. Gathered by Lewis Neec, but without flowers or fruits, in the kingdom of Mexico, by the road from Ixmiquilpan to Cimajtan, as well as between Tistada and the river Azul. The trunk is thick, twelve feet high, with a grey bark. Branches horizontal; the smaller shoots erect;
all very leafy. Leaves three inches long, and one and a half broad, slightly revolute; smooth above; roughish and veiny beneath, the veins forked. Footstalks thick and very short. Nee.

17. Q. acuta. Pointed-leaved Japan Oak. Thunb. Jap. 175. Wildl. n. 15.—Leaves oblong, pointed, entire, with parallel veins; round at the base; downy when young.—Observed by Thunberg in Japan. The branches are knotty, silk-coloured, dotted with white, smooth downy at the summit. Leaves alternate, stalked, smooth, when full-grown; covered at the back, when young, with rusty down. Spikes axillary, clothed with similar pubescence. Thunberg.

18. Q. magnoliaefolia. Magnolia-leaved Oak. Willd. n. 16. Nee in Annal. Scient. Nat. v. 3; 268. Fich. Misc. Hilp. v. 1. 103.—Leaves ovate-oblong, coriaceous, entire, shining; downy beneath; somewhat emarginate at the base. Fruit racemose.—Found by Louis Nee, in the kingdom of Mexico, between Chilpancingo and Tixtala, and about the river Azul. This is an elegant tree, twenty feet, or more, in height. Trunk thick, with a dark-coloured bark full of fissures. Branches horizontal; younger ones furrowed, and dotted with white. Leaves fix or eight inches long, and three broad, ovate, rigid; sometimes emarginate at the base; green and shining above; downy beneath, with the larger veins prominent, and the smaller reticulated. Footstalks thick, a line in length. Stipulas crisped, downy, deciduous. Female clylindra solitary, axillary, two inches long; the lower ones alternate, upper opposite. Acorns ovate, half covered by their hemispherical cup, which is the size of the seed of Cicer arietinum, its scales scarcely at all imbricated. Nee.

19. Q. lutea. Yellow-leaved Mexican Oak. Willd. n. 17. Nee in Annal. Scient. Nat. v. 3; 269. Fich. Misc. Hilp. v. 1. 105.—Leaves obvate, entire, shining; somewhat heart-shaped at the base; downy and yellow beneath.—Found in Mexico by the fame celebrated traveller and botanist. This agrees with the preceding in its mode of growth, and fructification, infomuch that it may be thought a variety; yet the leaves are very different. They are of a larger size, broader towards the end, and contracted towards the footstalk, as well as more deeply emarginate at the base; and their under side is clothed with ochre yellow pubescence.

20. Q. semiarispiffolia. Marking-nut-leaved Oak.—Leaves obvate, obtuse, coriaceous, entire; heart-shaped at the base; downy beneath; the young ones with spinous teeth. —Gathered by Dr. F. Buchanan, on the banks of the torrents in Upper Nepaul, where its Parbutte appellation is Caffir, and its Nawar name Ghrifi. This is a middle-sized tree, with angular branches, clothed when young with lacy down. Leaves evergreen, alternate, on short thick stalks, obvate-oblong, four or five inches in length, and two in breadth; more or less heart-shaped at the base; their upper surface smooth and shining; the under opaque, clothed with rusty down, and furnished with numerous, irregular, rather distant, transverse, prominent veins; their margin entire, slightly wavy. The extremity is usually rounded and obtuse, sometimes abrupt, sometimes tipped with a little spine. On young branches the leaves are ferrated with frong ipines, or even frumated, and clothed on both sides with rusty down. Stipulas in pairs, awl-shaped, erect, permanent, as long as the footstalks. Dr. Buchanan did not observe the flowers or fruit. The aspect of the adult leaves is much like those of Semecarpus Anacardium, or some of the entire-leaved species of Ficus. Section 2. Leaves more or less toothed or ferrated.

21. Q. glauca. Glaucous-leaved Oak. Thunb. Jap. 175. Banks le. Kaempf. t. 17. Wildl. n. 11. (Kas no ki: Kaempf. Aomen. 816.)—Leaves ovate, pointed; ferrated towards the extremity; glaucous beneath. Nut roundish. —Gathered near Nagaksu, in Japan, by professor Thunberg, to whom we are obliged for a specimen. He describes it as a very large tree, whose branches are somewhat umbellate, erect, round, purple, smooth, except some prominent white points. The leaves are alternate, above three inches long, and near two broad, with a blunt projecting point; their upper surface smooth and polished; the under covered with a fine glaucous measles, and marked with prominent, straight, parallel, but rather dim, obliquely transverse veins; the margin distinctly ferrated upwards. Footstalks about half an inch long, purple. Flowers axillary. Acorns, by Kaempfer's figure, axillary, often in pairs, of a roundish tumid shape, pointed, not an inch long, their cups short, feemingly marked with concentric lines; their flasks fimple, short and thick.

22. Q. annulata. Ring-cupped Oak.—Leaves ovate, pointed; ferrated in their upper half; somewhat glaucous and downy beneath. Fruit spiked. Nut oblong. Calyx furrowed concentrically.—Gathered by Dr. Buchanan, at various places in Upper Nepaul, bearing fruit, in December 1802. A very large tree, whose wood is excellent; the branches two or three together, smooth. Leaves evergreen, rigid, exactly like those of the last species, but somewhat silky beneath, and less glaucous; the young ones very silky. Stipulas linear, hairy, longer than the footstalks, deciduous. Male flowers in pendulous, hairy, yellowish, shortish spikes, springing from buds below the leaves, whose scales are imbricated in five rows: female from three to five, in solitary, axillary, upright, stalked, smooth spikes, about the length of the footstalks. Calyx of the female flowers globose, smaller than hempseed, composed of several concentric imbricated layers, of which the outermost is smooth and notched, the rest downy and entire. German globoso. Style very short and thick. Stigma three, obtuse. Acorns quite seflife on the common flower-stalk. Cup rather smaller than that of our British oaks, entire and even at the edge, composed of seven or eight concentric, annular, imbricated, crenate scales, externally silky. Nut ovate, acute, smooth and even, twice as long as the cup. The Parbuttes call this tree Phallila; the Nawar Gyphi, or Paza firinigeli.

We find great reason to think that it may be, as Dr. Buchanan conjectured, the same species with Thunberg's glaucus laft described. The leaves of his specimen flew a flight degree of pubescence about the veins, but have not the minute filkinles of our's. The greatest and most essential difference, if Kämpfer be as correct as usual, consists in the female infructescence. He delineates the acorns of glaucos on short, simple, axillary stalks, either solitary or in pairs; and Thunberg describes the flowers as axillary. In our plant the female flowers are indeed axillary, but they compose a stalked spike, and neither they nor the acorns have any partial stalks. Such differences are found between other species of Oaks, and prove essential and invariable. We therefore cannot but, for the present at least, rely on Kämpfer's known fidelity, and propose our Q. annulata as a distinct species.

23. Q. lamellifoila. Many-cupped Oak.—Leaves elliptico-oblong, pointed, ferrated, many-scaled; glaucous and somewhat downy beneath. Calyx of many concentric entire layers, as long as the nut.—Discovered by Dr. Buchanan, in the more remote woods of Nepaul, bearing fruit in December 1802. In the Nawar language it is called Tuppsjafari. The tree is lofty, with smooth bluntly-angular branches. Leaves alternate, five inches in length and two in breadth, elliptic-

K k 2
elliptic-oblong, rigid, taper-pointed, sharply ferrated; smooth and green above; glaucous and often finely downy beneath, with innumerable, prominent, crowded, flat, parallel, mostly opposite, oblquely transverse veins: the aspect and size of the leaves much resembling *Dillenia indica*. 

**Footnote**: An inch and half long, tumid at the base. *Stipulas* deciduous. Female flowers in short axillary spikes. 

*Acors ovate, pointed, the size of chestnuts, each completely enveloped and concealed by the large, globose, downy cup, which is as big as a small apple, and consists of eight or nine distinct, concentric, entire, imbricated layers, much more deeply separated than the rings of *Q. annulata*. An approach towards the genus *Fagus*, or *Caiffenes* of some authors, may be observed, as Dr. Buchanan suggests in this species, which is nevertheless a genuine *Quercus*, and far less doubtful than our *tribusalis*, n. 13. It proves however that the mere elongation of the acorn, beyond the cup, is not an indispensible character of the present genus. See also *tomentosa*, n. 42.

"Leaves ovate, pointed, ferrated, smooth. Calyx prickly."

—Native of Japan, about Nagafaki. A tree, with flatrated, smooth, spreading branches. *Leaves* alternate, flatked, an inch long, ovate, rounded at the base, pointed, smooth on both sides, with parallel veins; their upper half ferrated. Female flowers scattered over the young branches, solitary, nearly sessile. Cup of the acorn prickly, the size of a hazelnut. *Thumbl*. This species, like n. 13, appears, by its prickly cup, allied to *Fagus*; especially as *Kempfer*, who calls it *Fagus folia fraxinet*, describes the cup dry as splitting into three, four, or five parts. The nut is eaten by the Japanese, either raw or cooked.

25. *Q. ferrata*. Saw-leaved Japan Oak. *Thumbl*. Jap. 176. Willd. n. 20.—"Leaves oblong, ferrated, villous and downy, with parallel veins."—Native of Japan, flowering in May and June. A tree, with alternate, smooth, lilac-coloured, knotty, spreading branches, besprinkled with white tubercles. *Leaves* alternate, pointed, all acutely and equally ferrated, furnished with straight parallel veins; green above and very flaky when young; pale beneath; entire and downy at first, but subquently more slightly villous; their length from one to three inches. Male *flowers* in hairy, drooping, long-flailed *spikes*, each an inch long. Our specimen is in an early state of foliage, nor have we any account of the fruit, or female *flowers*.

"Leaves obovate-oblong, obtuse, deeply toothed; downy beneath."—Native of hills in Japan, flowering in April and May. A tree, with thick, erect, rugged, narrowed branches, besprinkled with dots and tubercles; downy at the summits. *Leaves* crowded about the extremities, on very short flalks, obovate-oblong, obtuse, with deep teeth dehitute of spines; villous above; downy beneath; plant, two inches long; their veins parallel. *Thumbl*. *Kempfer* says the wood is white.

27. *Q. lanata*. Woolly-leaved Nepal Oak.—Leaves elliptic-oblong, sharply ferrated, coriaceous; densely woolly beneath. Fruit in axillary solitary *spikes*. Calyx falcate, without prickles. Native of the mountains of Upper Nepal, flowering in April. Buchanan. The Parbuties call it *Banna*, or *Bunja*; the Newars *Sohei Shingali*. This is a tree of vast dimensions, with a fcaky bark, and rigid, brown, warty branches, clothed, when young, with dense white down. *Leaves* alternate, somewhat two-ranked, flaked, elliptic-oblong, sometimes rather obovate, pointed, from three to five inches in length, and two or more in breadth strongly and sharply ferrated, except at the very base, which is more or less rounded, and occasionally unequal; the upper surface green, shining, and naked, (except when young), but not quite smooth to the touch; the under clothed with fine, dense, uniform, white, woolly pubescence, and marked with prominent, parallel, but not very crowded, obliquely-transverse veins. *Footstalks* stout, downy, feebly an inch long. *Stipulas* ovate, membranous, deciduous. Male flowers in short, dense, hairy *spikes*, at the base of the young shoots, as they protrude from the bud. Calyx with five or six teeth. *Anthers* about five, feebile. Female flowers, as far as Dr. Buchanan could observe, on a separate tree, in very short, solitary, axillary *spikes*. *Acors* either solitary, or several crowded together, small, ovate, hairy, half covered by their feebly unarmcd cups.

28. *Q. diversijfolia*. Various-leaved Mexican Oak. Willd. n. 21. *Nee* in Annal. Scient. Nat. v. 3. 270. Fitzc. *Mifc*. Hiff. v. 1. 107. *Willd*.—Leaves ovate, undivided or deeply toothed; yellow and downy beneath. Fruit farked, globose.—Found by Louis Nee, between the villages of Chalma and Santa Rosia in New Spain. A *frub* from ten to fourteen feet high; its trunk feldom straight; the back cracked, dark-coloured; the branches alternate. *Leaves* either an inch and half long, and undivided, or two inches and a half, and deeply toothed; smooth and shining above; downy, and dull yellow beneath. *Footstalks* hardly a line in length. *Stipulas* oblong, reddish, membranous, contracted at the base, deciduous. *Acors* four or five, feebile, on a thread-flaked axillary flalk, two inches long. *Cup* the size and shape of a pea, covered with scales. *Nuts* scarcely projecting above a line beyond the cup. *Nee*. The fruit, being feebile, is evidently farked, not, as the authors quoted term it, racemose.

Pakhtenett's t. 196. f. 3, cited with doubt by Willdenow and Pursh, appears to belong, as Linnæus thought, to his own *Hippomane fipofs*. The shape of the leaves certainly does not agree with the above description, though perfectly answerable to Plummer's figure of this *Hippomane*, which is *Sapium theceflanum* of Willdenow, Sp. Pl. v. 4. 573, who there copies the fame fynonym from Linnæus, without any mark of uncertainty.

30. *Q. gramuntia*. Holly-leaved Montpellier Oak. Linn. Sp. Pl. 1413. Willd. n. 23. *Ait*. n. 6. (Hex folicis rotundiciribus et fipotis, e lucro gramuntio; *Mangi*. Monfr. 140.)—Leaves roundish-elliptical, nearly feebile, undulated, with deep fipons divaricated teeth; densely downy beneath; somewhat heart-flaked at the base.—Native of the wood of Gramout, near Montpelier, and of Spain. Cultivated in England in 1730. It blossoms in June. This is rather a small fragging tree, with numerous round grey branches, downy when young. *Leaves* evergreen, scarcely an inch long,
long, rigid, broadly elliptical, often nearly orbicular, very much undulated at the margin, their deep broad fimbriate teeth pointing every way; the upper surface dark green, rather glaucous, besprinkled with minute flary hairs; the under densely clothed with white entangled down. We have seen neither flowers, nor fruit. Willdenow appears mistaken in discounting the synonym of Magnoli, which answers extremely well to the Linnæan species, though indeed the author speaks of his plant as a variety of Q. Ilx.

It is, nevertheless, true that Linnæus confounded herewith a plant from Magnoli’s herbarium, which is not distinct from Q. Ilx.

31. Q. Ballota. Sweet-acorn Oak. Desfont. Atlant. v. 2. 350. Willd. n. 24. (Linn major; Clf. Hill. v. 1. 23.)—Leaves elliptical, coriaceous; entire or serrated; softly downy beneath. Bark even. Nut cylindrical, elongated.—Native of several places in the neighbourhood of mount Athos, according to professor Desfontaines, from whom we have a wild specimen. It flowers in May. This is a large and handsome evergreen tree, whose trunk is from twenty to thirty feet high; the wood hard, compact, and very useful; the bark even, not corky, though full of fissures; branches downy. Footstalks a quarter of an inch long, downy. Leaves various in shape, but more or less elliptical, an inch or half and long; either quite entire, or serrated with small fimbriate teeth; their upper surface, at least when young, besprinkled with minute flary hairs; the under always very white and densely downy. Male flowers in copious, long, lax, pendulous spikes, with usually seven flowers; female on the same tree, axillary, solitary or aggregate. Acorns cylindrical, an inch and half or two inches long, half an inch in diameter, easy and very palatable, either raw or roasted. Cup hemispherical, covered with numerous, obtuse, downy, closely imbricated scales.

32. Q. Ilx. Common Evergreen Oak, or Holm Oak. Linn. Sp. Pl. 1412. Willd. n. 25. Ait. n. 7.—Leaves ovate-oblong, acute, coriaceous; entire or serrated; hoary beneath. Bark even. Nut ovate. The varieties are: s, with lanceolate entire leaves; Smilax Dalech; Baup. Hitl. v. 1. part 2. 101. Suber succundus; Matth. Valgr. v. 1. 188, as to the figure: e, with lanceolate serrated leaves; Ilx; Matth. Valgr. v. 1. 186. Duham. Arb. v. 1. 123: 7, with rounder, less rigid, and more or less serrated leaves; Phellodrys; Matth. Valgr. v. 1. 189, as to the figure. Ilx. n. 3; Duham. Arb. v. 1. 124. This species occurs in various parts of the coast of Europe, and north of Africa, and is hardy, as well as evergreen, with us, thriving particularly near the sea, though of slow growth, flowering in May and June. It usually forms a large bushy tree, but occasionally rises with a straight naked trunk, and round head, to a great height. The wood is hard and heavy, valuable for many purposes. The French use it for pulleys in the navy. The bark is hard and even, not corky. Leaves various in shape and size; dark green, convex, and quite smooth; hoary or downy beneath; their edges either revolute and entire, or irregularly notched and serrated. Footstalks half an inch long, downy. Acorns usually two, on an axillary downy stalk, which is longer than the footstalk, ovate, hardly an inch long, with a scaly downy cup. They are eaten by hogs, but are very different in shape and quality from those of the last-mentioned species. So many varieties, or species, nearly corresponding with these two, are mentioned by authors, that it is difficult to understand them. The subject requires, and will deserve, a practical investigation. Lamarck, under the article Chêne, in his dictionary, mentions several kinds, which he knew but imperfectly, and which have no means of elucidating further, so that we dare not adopt, or attempt to reduce them to order.

33. Q. Suber. Cork Tree. Linn. Sp. Pl. 1415. Willd. n. 26. Ait. n. 8. Hunter’s Enc. Syll. 352, with a plate in Suber; Camer. Epit. 115. S. primus; Matth. Valgr. v. 1. 187. S. latifolium, perpetuo virens; Duham. Arb. v. 2. 391. t. 80. S. latifolium; Ger. Em. 1347, the middle figure only.—Leaves ovate-oblong, bluntish, coriaceous; entire or sharply serrated; downy beneath. Bark cracked, fleshy.—Native of the south of Europe, and north of Africa. Duhamel says it can hardly bear the climate of the north of France. It lives however in our English gardens, where it has been kept more than a century. The bark is remarkable for a thick fleshy coat, yielding the well-known substance called cork. The leaves much resemble the broad variety of Q. Ilx, nor do the acorns greatly differ from those of that tree. We have not been able to ascerten what authors mean by the Suber angustifolium non ferratum, the figure of which, Matth. Valgr. v. 1. 188. Duham. Arb. v. 2. t. 81, we have cited as our first variety of Ilx. We should prefix the Suber itself to be altogether a variety of Ilx, differing only in the bark; and that there might be a broad and a narrow-leaved variety of each; were not the dwarf tufted stumpy habit of the Cork Tree, on the sandy plains of Italy, Spain, &c. so peculiar. Yet this possibly may, as well as the nature of the bark, be owing to the soil, and in longitude the cork, according to Duhamel, degenerates. Willdenow says the leaves of Q. Suber are a little elongated at the base, running down into the footstalk, which is not the case with Ilx; but this character seems scarcely permanent.

34. Q. coccifera. Kermes Oak. Linn. Sp. Pl. 1413. Willd. n. 27. Ait. n. 9. (Ilx coccifera; Camer. Epit. 373, t. 37, 435 t. 17, 18. I. coccigera; Ger. Em. 1342.)—Leaves elliptic-oblong, rigid, smooth on both sides, with spreading, blythy, spinous teeth. Nut ovate. Calyx with spreading pointed scales.—Native of the south of Europe, and the Levant, flowering in the spring. This is a bushy evergreen shrub, celebrated for producing the kermes, a valuable article of dyeing, before the introduction of cochineal, and which afforded the color kermesinus, or crimson. The kermes is an insect, of the genus Coccus, which sticks to the branches, in the form of a red ball, the size of a pea. It is now out of use among dyers, and is only used by French apothecaries. The leaves of this shrub are, at most, but half the size of the Ilx, though they vary much in magnitude as well as figure. They are distinguished by their rigidity, smoothness on both sides, and their prominent needle-like marginal prickles. The scales of the mature calyx are also much more elongated and prominent than in Ilx or Suber, and of an angular awl-shaped figure.

Willdenow, not having seen a specimen, has misunderstood the
the nature of the calyx, and has in other respects altered
Desfontaines' specific character for the 

36. Q. rigidia. —Rigid-leaved Oak. Willd. n. 29. —
(Hebe pseudosaccocladia, plana maximis, nune cylind-
ricas, un fruticos, cupul di echinata; Tourn. Cor. 42.)
—"Leaves oblong, undivided, with spiny ferratures, 
smooth; glaucous beneath; heart-shaped at the base. Foul-
flanks beard at the summit. Scales of the calyx of the 
fruit rigid, spreading." —Native of the coast of Caramania. 
Wildeneke. A pretty species, sufficiently distinct from its 
allies. Branches pale brown, dotted. Leaves oblong, an 
inch or rather more in length, rigid, with spiny ferratures; 
deep green and shining above; glaucous beneath; cordate 
at the base. Fruitflanks very short, smooth, except at the 
top, where a line of brownish hairs, on each side, runs up 
the midrib. Calyx of the fruit feathery, beget with rigid, 
woody, lanceolate, spreading scales. Willd.

A specimen before us, gathered by the late Dr. Brouio-
net at Algiers, answers precisely to this description, espe-
cially in the curious character of the hairy lines, running a 
little way up the midrib of the leaf; but the foliage is 
equally green and shining on both sides. The calyx 
reflected that of cocciferas, but its inner scales are longer, 
and more spreading.

37. Q. rotundifolia. —Round-leaved Spanish Oak. Lame-
rack Dicr. v. 1. 723. Willd. n. 30. —"Leaves obovate-
oblong, abrupt, with spiny teeth; heart-shaped at the 
base; smooth above; downy beneath." —Native of Spain. 
Seen by Lamarck, in a young state, in the garden of Mont. 
Cels, and by Willdenow dry without fructification. The 
branches are round and downy. Leaves flaked, an inch or 
more in length; glaucous-grey, and not quite smooth, above; 
white and cottony beneath. The acorns are faked to be large 
and long, edible, like chestnuts. This description is not in-
applicable, on the whole, to our n. 31, Q. Bullata.

38. Q. humilis. —Dwarf Portugalcele Oak. Lamarck 
Dilc. v. 1. 719. Willd. n. 31. Q. pedem vix supparas; Bauh. Pin. 420. Robur 71; Chuf. 
Hist. v. 1. 19.) —Leaves obvate, with spiny ferratures; 
heart-shaped at the base; downy beneath. Calyx of the 
fruit flattened. Nut oblong. —Found by Clufius in barren 
fandy ground near Lisbon, very abundantly. The whole 
plant is rarely more than a foot high when wild; though 
Lamarck says it becomes twice or thrice as tall by culture. 
The young branches are downy. Leaves an inch, or inch 
and half long, on short footflanks; smooth and shining 
beneath; downy and hoary beneath; their larger veins 
furrowed and parallel. The acorns are described as more bitter 
than our common oak, their form oblong, their cups remarkably 
short and flattened.

39. Q. luftanica. —Portuguese Gall Oak. Lamarck 
Dilc. v. 1. 719. Willd. n. 32. (Q. valentina; Cavan. 
C. v. 2. 25. t. 129; Robur 4; Chuf. Hist. v. 1. 18, and 
R. 5; ibid. 19. Galla five Robur major; Ger. Em. 1348; 
q. minor; ibid. 1349.) —"Leaves elliptical, with deep 
pointed ferratures; downy beneath. Fruit raceme. Calyx 
hemispherical. Nut oblong." —Native of Portugal, and 
perhaps Spain. Lamarck says this species consists of several 
varieties; all very low frutis, subject to bear galls; their 
branches copious and fiedder; their leaves small, intermediate 
in form between the evergreen and the ordinary oaks of 
Europe. Willdenow describes the leaves an inch in length, 
oblong, obtuse, rigid; their ferratures somewhat pointed 
the upper surface polished and smooth; the under hoary 
with slender, hairy, crowded hairs. Footflanks short. Fruit 
racemose, or rather, as we should imagine, farked. He 
adds that the figure of Cavanilles fearlessly answers to the 

40. Q. infectoria. —Oriental Gall Oak. Olivier's Travels. 
English edition, v. 2. 42. t. 14, 15. Willd. n. 33. —Leaves 
ove-oblong, very smooth on both sides, deeply toothed, 
sharply serrated, deciduous. Fruit feathery. Calyx tenta-
flated. Nut elongated, nearly cylindrical. —This oak, ac-
cording to Olivier, is scattered throughout all Asia minor, 
from the Bosphorus as far as Syria, and from the coasts of 
the Archipelago, as far as the frontiers of Persia. It fel-
dom attains the height of six feet, and the stem is crooked, 
with the habit of a frutus rather than a tree. The leaves 
are an inch or half inch long, deciduous, bright green, 
smooth on both sides, but paler beneath; their ferratures 
deeid and broad, not acutely pointed. Fruit foliary, nearly 
feathery. Cup flightly downy, its scales not very distinct. 
Acorn two or three times larger than the cup, smooth, 
early cylindrical. The galls produced on the young 
branches of this oak, from the puncture of a species of 
Diptolepis, are preferred to all others for dyeing, and are a 
great article of the Levant. (See GALLS.) Olivier obser-
ves that the plant bears a number of different galls, 
besides the above, which are neglected, as useless.

41. Q. menzonnii. —Pointed-toothed Mexican Oak. 
Willd. n. 34. (Q. callanea; Nee in Annal. Scient. Nat. 
short, acute, alternate, smooth, much sub-divided. Leaves 
three inches long, and one broad, acute; abrupt and heart-shaped at the base, their ferratures 
awed; the upper surface green and smooth; the under 
ober clothed with fine yellow down. Footflanks two lines 

42. Q. tomentosa. —Downy Mexican Oak. Willd. n. 35. 
(Q. pedunculareis; Nee in Annal. Scient. Nat. v. 3. 270. 
Fitch. Mifs. Hisp. v. 1. 106. Willd.) —"Leaves oblong-
oveate, with tooth-like notches; densely downy beneath. 
Fruit racemose. Nut globose, nearly covered by the calyx."  
—Native of New Spain, in the road from Mexico to Aca-
pulco, beyond the river Mescal. A tree, twenty feet high, 
with an upright trunk, and grey brittle bark. Branches 
numerous, alternate, clothed with dene reddish wool. 
Leaves five inches long, hardly two wide, crowded; obtuse 
at the base; pointed at the end; bordered with tooth-like 
notches; green and smooth above; downy, with promi-
inent veins, beneath. Footflanks downy, very short. Fe-
male flowers on an axillary solitary flalk, three or four inches 
long. Acorn but little bigger than pepper-corns, each al-
most entirely concealed in its scaly, downy, reddish cup. 
Nee. This species agrees with our thirteenth, tribulus, 
in having its acorn concealed by the cup. The fruit is 
described, by the authors we are obliged to copy, as race-
moe. We have seen no specimens, but analogy would 
insue us to suppose it rather spike.

Mifs. Hisp. v. 1. 109. Willd. —"Leaves ovate, crenate, 
undulates; acute at each end; downy beneath. Nut 
fearedly longer than the calyx." —Native of New Spain, 
between Tixtala and Chilpancingo. A tree twenty or 
twenty-five feet high. Trunk erect. Bark brittle, affo-
coloured. Branches horizontal; the young ones creaf, fur-
rowed,
rowed, villous. Leaves alternate, from five to seven inches long, and three broad; green and shining above; more or less downy, and flesh-coloured, or reddish-brown, beneath; the margin undulated and crenate, the notches rounded, their edges turned towards the point of the leaf. Fruit supported by a very short common flalk. Calyx hemispherical, the size of Chick peas, Cicer arietinum; its scales acute at the point. Nut but little larger than the calyx. Plucked in with a very fine common flalk, with numerous closely-imbicrated scales. Michelau says the bark is whitish, peeling off in long strips.

44. Q. *splendens*. Silky-leaved Mexican Oak. Willd. n. 37. Nee in Annal. Scient. Nat. v. 3. 275. Fitch. Misc. Hilp. v. 1. 113. *Willd.*—"Leaves oblong-ovate, bluntly toothed; slightly downy above; densely silky beneath."—Native of New Spain, near Taxala. Trunk ereth, much branched, fifteen feet high. Branches partly horizontal, partly ereth, clothed with red shining down. Leaves scattered, crowded, three inches long, and an inch and half broad; green, with a thin downy coat, above; thickly clothed beneath with shining pubescence, the midrib only being prominent; their edges bluntly and unequally toothed. Footstalks very short, with an awl-shaped villous stipula at the base. Flowers and fruit not observed. *Nee.*

45. Q. *ruga*. Rugged Mexican Oak. Willd. n. 38. Nee in Annal. Scient. Nat. v. 3. 275. Fitch. Misc. Hilp. v. 1. 112. *Willd.*—"Leaves ovate-oblong, coriaceous, rugose; toothed towards the end; heart-shaped at the base; downy and rusty beneath."—Native of the woods of Huifquiluca and Ocuila, in the way from Mexico to Santo Cristo de Chalma. A medium-sized tree, having numerous, alternate, round, grey branches, rough with minute prominent points. Leaves three inches in length, hardly two in breadth, thick and coriaceous; rugged, green and shining on the upper side; brown and downy at the back; heart-shaped at the base; the margin toothed from the middle to the extremity. Footstalks two lines long, thickened at their base. Female flowers in scaly axillary clusters. *Nee.*

46. Q. *macrophylla*. Large-leaved Mexican Oak. Willd. n. 39. Nee in Annal. Scient. Nat. v. 3. 274. Fitch. Misc. Hilp. v. 1. 111. *Willd.*—"Leaves ovate, coriaceous; tapering and heart-shaped at the base; downy beneath. Fruit spiky."—Found by Louis Nee, the discoverer himself of the five preceding species, in the district of Chilpancingo and La Curva, and on the mountains of Quirapu, in New Spain. This is a tree, thirty feet high, with a stout upright trunk, and dense head. The principal branches are horizontal; the site upright, furrowed when young. Leaves a foot long, and seven or eight inches broad; rounded at the end; gradually tapering down to the emarginate, or heart-shaped, base, where they measure only four lines across; their upper surface green and shining; the under yellowish, clothed with very minute down; the margin crenate and wavy. Footstalks very short and thick. Female flowers feathery on a common stalk, and encompassed with downy bristles. *Nee.*

This is one of the tallest trees produced in the southern parts of the United States, and remarkable for the beauty of its form, as well as the large size of its acorns, which are plentiful and sweet, a delicious and beneficial food for hogs and other wild animals. The wood is excellent, much used for making wheel-carriages, and very readily split as to serve for balked-work and brooms. The leaves are fix inches, or more, in length, and three broad; silky in the spring; smooth and glaucous in summer; sometimes very downy on old trees. Footstalks an inch long; Stamine five to ten. Acorns an inch and half long; ovate; their cups shallow, covered with numerous closely-imbicrated scales. Michelau says the bark is whitish, peeling off in large strips.

48. Q. *virens*. Chinquapin, or Dwarf Chefnut Oak. Pursh n. 34. (Q. *pumila*; Willd. n. 41. Q. *Primus*, var. 4, pumila; Michaux Querc. n. 5. t. 9. f. 1. Q. Primus Chaquapin; Michaux Arb. v. 2. 65. t. 16, good. Pursh.)—Leaves on short flalks, obovate, smooth, glaucous beneath; tapering at the base; with nearly equal, dilated, acute, callous-tipped, tooth-like ferratures. Calyx of the fruit hemispherical. Nut ovate. Found on dry mountainous lands, from Pennsylvania to Carolina, flowering in May, when, according to Mr. Pursh, it is highly ornamental. This is a humble floribunda, not above three or four feet high. The young leaves are whitish and downy beneath; the adult ones smooth and glaucous, scarcely above one-third the size of the preceding. Female flowers, according to Michaux, small, two or three together, on a short, solitary, axillary flalk. Acorns of a middling size, with a thin, nearly hemispherical, cup.

49. Q. *montana*. Rock Chefnut Oak. Wildl. n. 42. Pursh n. 32. (Q. *Primus*; Sm. in Abbots Inf. v. 2. 163. t. 82. Q. *Primus*, var. 2, monticola; Michaux Querc. n. 5. t. 7.)—Leaves on short flalks, obovate, acute; downy and white beneath; with nearly equal, dilated, short, blunt, callous-tipped, tooth-like ferratures. Fruit in pairs, on short flalks. Calyx hemispherical, with rugose scales. Nut oblong-ovate. Found abundantly, in rocky situations, on the mountains of North America, from New England to Carolina, flowering in May. Michelau suggests that this species would be well worth cultivating in Europe. The tree rises to the height of fifty feet; the wood is tough and very useful, the bark excellent for tanning. It differs from Q. *Primus*, n. 47, with which it has been confounded, in the confluent white downfalls of the under side of the leaves, which are much smaller and less dilated upward. The acorns moreover are but half the size of that species, and more oblong, two together on a very short flalk.

50. Q. *leucodendron*. Swamp White Oak. Wildl. n. 43. Pursh n. 31. (Q. *Primus*, var. 5, tomentosa; Michaux Querc. n. 5. t. 9. f. 2. Q. *Primus* difcolor; Michaux Arb. v. 2. 46. t. 6. Pursh.)—Leaves nearly feith, ovate; downy and white beneath; with very broad, unequal, obtuse, callous-tipped, lobe-like teeth. Fruit in pairs, on long bristle-pointed flalks. Calyx hemispherical. Nut oblong-ovate. Native of low wet woods, from Pennsylvania to Carolina, flowering in May. Pursh. It grows to a very large tree. The leaves have extremely broad shallow teeth, or, as they might be called, lobes, approaching to the figure of our common English Oak leaves; their under side white and very downy. The acorns are sweet and edible, like most of the Primus tribe. Wildenow says the teeth are occasionally variable in size, one or two of them being sometimes remarkably elongated, and that the base of the leaf is more entire than in the foregoing.

51. Q. *calycina*. Yellow Oak. Wildl. n. 44. Pursh n. 33. (Q. *Primus*, var. 3, scuminata; Michaux Querc. n. 5. t. 8.)
Leaves on long footstalks, oblong-lanceolate, pointed; somewhat downy beneath; with numerous, nearly equal, dilated, acute, callous-tipped, tooth-like teeth. Calyx hemispherical. Nut roundish-obovate. — Found in the Allegheny mountains, and on the banks of the Delaware, flowering in May. Pursh. Michaux says it occurs in all the fertile countries to the west of those mountains; and as the temperature of that climate agrees with the north of Europe, the tree in question would be well worth trying here. The wood is excellent; bark very serviceable in tanning; and the acorns sweet. The tree is large and handsome, seventy or eighty feet high. Leaves much like those of our Sweet Chestnut in form, but glaucous and often downy beneath. Acorns much rounder than in any of the four preceding, and shorter in proportion to the cup. These Fine-forked Oaks, Primus and its allies, seem not to have as yet attracted the notice of European cultivators, perhaps from their having been improperly confounded by botanists. The above accounts of their distinctions, and their valuable qualities, it is hoped, may cause them to be fought out, and introduced into this country. Their different acorns might freely be easily imported.

Section 3. — Leaves lobed at the extremity.

52. *Q. aquatica*. Water Oak. Soloand. in Ait. Hort. Kew. ed. 1. v. 3. 357. ed. 2. n. 11. Pursh n. 45. Michaux n. 11. Michaux Querc. n. 11. t. 19. t. 20. f. 1. 3. 4. 5. and t. 21. (Q. folio cuneiformis, oblonge trifolius, intermedio producitore; Cron. Virg. 149. Q. folio non ferrato, in fummitate quasi triangulo; Catecb. Carol. v. t. 20. Herb. Linn.). — Leaves wedge-shaped, smooth; tapering at the base; dilated and obscurely three-lobed at the end, the middle lobe largest. Calyx nearly hemispherical. Nut roundish. — Native of swamps in North America, from Maryland to Florida, blooming in May. Miller is said to have cultivated this species in 1748, but it is little known in England. The tree is forty feet high; its wood, according to Pursh and Michaux, is little esteemed; but the latter is of opinion that it might prove more valuable if felled in winter; he mentions also that the tree is not peculiar to swamps, or inundated meadows, but occurs sometimes in dry sandy ground, as on plains near the sea-coast of Florida. Few trees vary so much in the shape of their leaves, according to age or situation, as this. The proper form of its foliage is wedge-shaped, much elongated and tapering at the base; dilated, rhomboid, or very slightly and bluntly three-lobed at the extremity; the edges entire; both sides usually smooth. Footstalks variable in length, but rather short; clothed, when young, with flary hairs, which are sometimes scattered over the back of the young leaf. Some of its leaves, however, even on the same tree, are deeply three-lobed; and those of young plants are, the first year, oblong and quite entire; the next two or three seasons, variously toothed and finuated; in some so much that botanists know not how well to distinguish its varieties from some of the following species. The acorns are short and roundish, with a shallow cup, and stand generally in pairs, on short stalks.

53. *Q. nigra*. Barren Oak, or Black Jack. Linn. Sp. Pl. 1413. Wild. n. 46. Ait. n. 12. Pursh n. 15. Sm. in Abbot's Inf. v. 2. 115. t. 12. Q. folio cuneiformis, folio trifidum, ad inhabras accedente; Catecb. Carol. v. t. 19.— Leaves wedge-shaped; somewhat heart-shaped at the base; dilated, abrupt, and very slightly three-lobed at the end; the middle lobe short; smooth above; fully beneath. Calyx hemispherical, with membranous scales. Nut roundish-ovate. — In barren sandy or gravelly woods, from New Jersey to Florida, blooming in May. This tree is of low growth, especially in the more northern states. It bears abundance of acorns, very good food for hogs. The wood is small, but excellent for fuel.

54. *Q. triloba*. Downy Black Oak. Wild. n. 47. Ait. n. 13. Pursh n. 14. Michaux Querc. n. 14. t. 4. (Q. rubra; Abbot's Inf. v. t. 90. t. 52.)—Leaves wedge-shaped, with three terminal, bluntly-pointed lobes; the middle one longest; downy beneath. Calyx of the fruit flatish. Nut nearly round. — Native of barren tracts, near the sea-coast, from New Jersey to Georgia, blooming in May. It was brought to England in 1800, by Meffra. Frazer. The tree is fifty or sixty feet high, of rapid growth, even in a poor soil. Michaux describes it as very fit for making live fences; though the wood is most generally used in America for palings. The leaves are much smaller than those of *Q. nigra*, rounded, not heart-shaped, at the base, and with longer footstalks. Their lobes are direct, not laterally dilated, each tipped with one or more small bristles, and the under side is covered with dense white down. The foliage of young flocks, that spring up where forests of this tree have been burnt, are often near a foot long, deeply pinnatifid, and sharply lobed; as represented in Michaux, t. 26. f. 2.

55. *Q. nigra*. Dwarf Jugged Oak. Wild. n. 48. Pursh n. 13. (Q. aquatica; Sm. in Abbot's Inf. v. 2. 117. t. 59. Q. aquatica elongata; Ait. n. 11. — Leaves oblong-wedge-shaped, smooth, somewhat finuated; three-lobed at the extremity; lobes divaricated, pointed, the middle one longest; forks of the vein downy beneath. — In barren lands, called pine-barrens, of South Carolina, flowering in May. Pursh describes it as "a low-growing species, always keeping distinct from *Q. aquatica*." The leaves are almost sessile, two or three inches long, much more distinctly lobed than in *aquatica* or *nigra*, and more finated or angular lobes, than in any of the three last described. The acorns are almost globular, with a very shallow cup.

Section 4. — Leaves finuated, with pointed lobes.

56. *Q. hemisphérica*. Hémisphérique Oak. "Bartram's Travels 320." Wild. n. 49. Pursh n. 12. (Q. aquatica maritima; Michaux Querc. n. 11. t. 20. f. 2.)—Leaves oblong-wedge-shaped; undivided, three-lobed, or finuated; smooth on both sides; lobes pointed. — Native of Georgia and Florida. Some of the leaves are very deeply three-lobed, or pinnatifid; others linear-oblong and undivided. Wildenow says they are evergreen, and that the foliage of the young plant is like *Q. phellos*, our first species, as to be hardly distinguishable. Michaux, however, affirms this supposed species to be but a maritime variety of *aquatica*, and Pursh thinks it a young plant of that kind.

57. *Q. elongata*. Downy-leaved Oak. Wild. n. 50. Ait. n. 14. (Q. falcata; Michaux Querc. n. 16. t. 28. Pursh n. 12. Q. dicyfer; Ait. ed. 1. v. 3. 358.)—Leaves downy beneath, finuated, with three or more somewhat falcate, bristle-pointed lobes; the terminal one elongated, jagged. Calyx hemispherical. — In sandy soil, near the sea-coast; from New Jersey to Georgia, blooming in May. A very large tree, commonly called Spanish Oak; its southern flates, Red Oak. Pursh. The height of the tree is fifty or sixty feet. Leaves on long stalks; obtuse or rounded at the base; deeply lobed, or in some measure palmate; the lobes often recurved, or fiddle-shaped; taper-pointed; and more or less notched at the end, each segment tipped with a long bristle. Acorns small, roundish; its cup hemispherical, with lax...
lax scales. The leaves of young trees are said to be very like those of *tigliob. n. 54.

58. Q. *tigliob. Dyers' Oak, Black Oak, or Quercitron. Willd. n. 51. Ait. n. 15. Pursh n. 16. Q. tigliobia angulosa; Michaux Querc. n. 13 t. 24. Q. dye; Willd. Arb. 274. 1.—Leaves downy beneath, obtuse-oblong, dilated, widely finuated; lobes short, obtuse, thinly toothed, bristle-pointed. Calyx of the fruit flat underneath. Nut globose.—In all large woods, particularly in the mountainous parts, from New England to Georgia, flowering in May. It is one of the largest trees of the American forest, highly valuable for its timber, as well as bark, which is so very superior in tanning to any other species of Oak. Pursh. In this state, this Oak is found by the *little in a good foil, always at a distance from the sea, attaining its greatest size, which is eighty feet in height, and eight in diameter, in the valleys between the high mountains of North Carolina. The bark is used by tanners, throughout the north and west parts of the United States. It gives a yellow color, whence the name of Querciton, and which enhances the value of the leather. The bark, bruised and powdered, was in great request among dyers in France, before the war interrupted this branch of commerce. The leaves are conspicuous for their broad, angular, abrupt figure, a span long, and nearly as wide, with shallow sinuses, and bristle-tipped angles. Acorns almost fleshy, globular, with a feby, hallow, flat-topped cap.

59. Q. dye; Willd. n. 52. Pursh n. 17. Sm. in Abbot's Inf. v. 2. 111. t. 56. (Q. tigliobia *flote; Michaux Querc. n. 13 t. 25. Q. virginiana, venis rubris muricata. Plak. Phyt. t. 54. f. 5.)—Leaves downy beneath, obtuse, pinnatifid; leaves oblong, toothed, bristle-pointed. Calyx turbinate. Nut ovate.—In large forests, from Pennsylvania to Carolina, flowering in May. This resembles the preceding and Q. coccineus. n. 61.

The young expanding leaves are covered with white down on both sides, which is not the case with either rubra or coccina. Pursh. This differs from the last in having much more finuated, or pinnatifid leaves, and larger, more ovate, acorns, whose cups are turbinated, or tapering at the base.

The qualities of the wood and bark probably agree with the *tigliobia, or Michaux, who considers the present plant as but a variety, would have mentioned the contrary.

60. Q. rubra. Mountain Red Oak. Linna. Sp. Pl. 1413. Willd. n. 53. Ait. n. 16. Pursh n. 20. Michaux Querc. n. 20 t. 35, 36. Abbot's Inf. v. 2. 205. t. 163. (Q. eufili *divifura. folis amploribus aculeatis; Plak. Phyt. t. 54. f. 4.)—Leaves smooth, oblanceolate, on long stalks; lobes acute, sharply toothed, bristle-pointed. Calyx of the fruit flat underneath. Nut ovate.—Native of forests on a fertile soil, from Canada to Pennsylvania, and in all the country west of the Alleghany mountains, blooming in May. It was cultivated by Miller before 1739, and is to be found in several plantations. A large and handsome timber tree, of rapid growth; its wood highly useful for building and for carriages; and the bark is said by Michaux to be the very best known for tanning, the European tanners, settled in America, having found it, by experiment, more efficacious than any of the oak bars of Europe. The tree is ninety or one hundred feet high. Leaves four or five inches long, on footed stalks about half that length; unequally finuated or pinnatifid, with rather spreading, but not remote, lobes, whose ends are very acute, as well as here and there, sharply toothed, each tooth and point tipped with a low bristle. Acorns rather large, ovate, with a short flat-bottomed cup. The leaves turn of a deep red in autumn, which is common to most American trees and shrubs, in a greater or less degree. Pursh says, this is exclusively known by the name of Red Oak, though various others are so denominated in several parts of America.

Q. *ambigua. Michaux Arb. v. 2. 120. t. 24. Pursh n. 19, is supposed to be the latter to be a hybrid between this and the following.

61. Q. coccina. Scarlet Oak. Willd. n. 54. Ait. n. 17. Pursh n. 18. Michaux Querc. n. 18 t. 31, 32. (Q. rubra s; Ait. ed. 1. v. 3. 357.)—Leaves smooth, oblong, deeply and widely finuated, on long stalks; lobes divided, acute, sharply toothed, bristle-pointed. Calyx of the fruit turbinate, half as long as the nut.—Native of woods, on a fertile soil, from New England to Georgia, blooming in May. This species has not, like other American trees brought to Europe, been cultivated before the end of the 17th century, by bishop Compton, as well as by the first earl of Portland. The bright red of the autumn gives the tree a beautiful and striking appearance, both in its native forests and our European plantations. It nearly equals the preceding in size; the wood, according to Michaux, is better, but the bark less valuable. The leaves are larger, with deeper, more rounded, sinuses, and more dilated lobes. Acorns half covered by the deeper, more turbinated, cup.

62. Q. *catheài. Barren Scrub Oak. Willd. n. 55. Pursh n. 21. Michaux Querc. n. 17. t. 29, 50. (Q. rubra s; Sm. in Abbot's Inf. v. 1. 27. t. 14. Q. eufili *divifura. folis amploribus aculeatis; Catheài. Carol. v. 1. t. 23.)—Leaves smooth, oblong, wedge-shaped at the base; deeply and widely finuated, on short stalks; lobes three or five, divided, acute, two or three-cleft, bristle-pointed. Calyx of the fruit turbinate, half as long as the nut.—Native of dry barren ground in Maryland, Virginia, Carolina, and Georgia, abundantly flowering in May. This species is shrubby, not above fifteen feet high; its wood of a bad quality, used only for firing. The shortness of the footstalks, and the fewness of the lobes of the leaves, added to their acute base, are sufficient botanical distinctions between the present and the two last, especially as the size and quality of the tree are so unlike those species.

63. Q. *palustris. Marl or Pib. Oak. Willd. n. 56. Ait. n. 18. Pursh n. 23. Michaux Querc. n. 19. t. 33, 34.—Leaves smooth, oblong, deeply and widely finuated, on long stalks; lobes divided, parallel, acute, sharply toothed, bristle-pointed; forks of the veins densely woolly beneath. Calyx of the fruit flattened. Nut nearly globose.—Native of low swampy woods, from New England to Pennsylvania, and in the Illinois country, flowering in May. Moira. Frater are recorded as having brought this species to England in 1605, but it was previously cultivated in Holland and France. This is a large tree, whole wood is tough, used for making spokes of wheels. The leaves are smaller than those of rubra or coccina, and with more numerous lobes than *catheài; their sinuses rounded and very wide, and the forks at the origin of their veins marked by a tuft of glandular hairs. The acorns are small, globular, with shallow cups, and generally very abundant.

64. Q. * jovisfolius. Pointed-leaved Mexican Oak. Willd. n. 57. Nee in Annal. Scient. Nat. v. 3. 267. Fifich. Mitte. Hifp. v. 17. 182. Willd. 11. 1. Nos. 150. t. 152. Q. jovisfolius latifolius, taper-pointed; unequal at the base; lobes toothed, bristle-pointed; forks of the veins villous beneath. Fruit racemose.—Native of New Spain, in the road from Acapulco to Mexico. This is the largest of all the Oaks in New Spain. Trunk thick, twenty-five feet high, ornamented with a dense head of innumerable branches. Leaves from five to seven inches long, an inch and a half or two inches.

Vol. XXIX.
inches broad, their footstalks an inch in length; ovate and unequal at the base, gradually contracting upwards to a sharp point, fruticate, beaft with awl-shaped teeth; green and shining above; reddish and veiny beneath, the forks of the veins villous. Female flowers in axillary four-flowered clusters, (or rather, we presume, flakes.) German ovate. 

Acorns small, feebly so big as a pea, nearly covered by the cup, which is clothed with blackish scales. 

65. Q. candicans. Hoary Mexican Oak. Willd. n. 58. Nee in Amil. Scient. Nat. v. 3. 277. Fitch. Mif. Hilp. v. t. 115. Willd.—Leaves obvate, fruticate; white and downy beneath; lobes toothed, bristle-pointed.—Native of New Spain, in sandy ground near Tistala. A tree of a middling size, with a dense head of upright branches. Leaves nine inches long, four wide, tapering at each end, fruticat, with bristle-pointed teeth; green and smooth above; white and downy beneath. Footstalks four lines in length. Flowers and fruit not observed. 

66. Q. ilicifolia. Holly-leaved, or Bear Oak. "Wangen. Ann. 79. t. 6. f. 177." Willd. n. 59. Ait. n. 19. (Q. Baniferi; Michaux Querc. n. t. 27. Pursh n. 21. Q. aquatica? Sm. in Abbot's Int. v. 2. 157. t. 79?)—Leaves obovate-wedge-shaped, with three or five deep bristle-pointed lobes, entire; downy beneath. Fruit fruticated, in pairs.—Found in dry barren fields, and on mountains, from New Jersey to Virginia, flowering in May; covering, wherever it occurs, large tracts of ground, thence termed Oak-barrens. It is known by the name of Bear Oak, Black Scrub Oak, and Dwarf Red Oak. Pufie. A shrub four to six feet, occasionally more, in height, with downy branches. Footstalks downy, near an inch long. Leaves two inches, or two inches and a half long, and near two wide, tolerably uniform, acute at the base, cut into five, rarely but three, deep divaricent, broad, acute lobes, entire at the margin, and feebly toothed at the summit, though tipped with one or two bristles; the upper side green, veiny, and smooth; the under pale, and finely downy. Female flowers in pairs, on thick, solitary, axillary, downy footstalks, much shorter than the footstalks. Acorns about half an inch long, nearly globular, half covered by their feebly hemispherical cups. Michaux thinks this species would serve well for making quick hedges. A specimen from Kalem, unnamed, is in the Linnean herbarium.

67. Q. Pseudopuber. Baffard Cork Oak. "Santi Viagg. 156. t. 44." Spreng. "Antiqu. Bot. 16. t. 11." Willd. n. 65. Descou. Atlant. v. 2. 348.—Leaves ovate-oblong, fruticate, hoary beneath; lobes numerous, pointed, entire. Bark fungous, cracked. Nut ovate. Calyx mucrated, with lax, recurved, linear scales.—Native of the mountains of Tuscany, Spain, and Barbary. Descoues termed it on mount Atlas, and the abbé Durand near Tangier. A tree fifty or sixty feet high, whole bark is corky, though less so than in Q. Suber, n. 35. Young branches downy or hoary, sometimes smooth, fruticated. Leaves deciduous, an inch and a half to three inches long, an inch or an inch and a half wide, acute; entire and lightly heart-shaped at the base; somewhat dilated upwards, and bordered with numerous, uniform, small, broad, acute, lobes or serratures, separated by roundish fimbriae; upper surface green and smooth; under glaucous, hoary, or somewhat downy. Acorns on short stalks, ovate, above an inch long, half covered by the cup, which is downy, and clothed with lax bluish scales, recurved at their tips. Desfontains says the leaves of young trees are deeply fruticated and serrated; those of old ones more feebly so. In our specimens from Durand and Broadmoor, the under side is feebly downy, except a dense fringe to the mid-rib. The transverse veins are more numerous, straight, and parallel, than in Sprengel's plate. Footstalks rather above half an inch long, smooth or downy. Acorns nearly sefate, crowded at the ends of the branches. Yet we think it must be, at least, the plant of Desfontaines.

68. Q. Argiopha. Great-prickly-cupped Oak, or Ve- landia. Linna. Sp. Pl. 1414. Willd. n. 61. Ait. n. 20. Mill. le. t. 215. Oliver's Travels, English edition, v. 2. 44. t. 13. (Q. orientalis, calloca folio, glan locundit in cupula craffa et floquosa; Tourn. Cor. 40. Velani; Tourn. Voy. t. 129. Querc. Cerri; Dale. Hilt. Vol. 1. t. 7.)—Leaves oblong-oblong, with bristle-pointed tooth-like lobes; hoary beneath. Calyx of the fruit very large, hemispherical, with lanceolate, elongated, spreading scales. —Native of the Levant. Miller cultivated this Oak in 1731. The tree is not so lofty as some other species, nor is the wood much esteemed, or used, but in cabinet work. Leaves fruticate, about three inches long, bright green; a little downy at the back; their edges, as in the last, very coarfly and acutely serrated, rather than lobed, each tooth tipped with a brily point. Acorn large, obtuse, a little hollow at the top. Cup suffused, woody, two or three inches in diameter, from the projection of its numerous, oblong, thick scales. These cups are used, as well as the gall-nut, (see n. 40.) by the Orientals, Italians, and English, in dyeing, and are a considerable article of commerce. Tournier says the modern Greeks call these acorns Velani, a corruption of Vaka, and the tree Velanida. The young acorns and cups, gathered from the tree, are much more esteemed than such as fall of themselves, when fully grown, and fell for twice the price of the latter. Dalechamp, Lobel, and Boughin, mislabe the unripe cup and acorn of this species, as belonging to Q. Cerri, n. 83.

Sect. 5.—Leaves fruticated, with blunt or pointlefs lobes.

69. Q. alba. White Oak. Linna. Sp. Pl. 1414. Willd. n. 62. Ait. n. 21. Pursh n. 29. Michaux Querc. n. t. 5. (Q. alba virginiana; Catelb. Carol. v. 1. t. 21. f. 2.)—Leaves oblong, deeply pinnatifid; glaucous beneath; lobes linear-oblong, obtuse, entire, dilated upwards. Fruit fruticated. Calyx depressed, warty. —Native of woods, on a fertile soil, from New England to Carolina, flowering in May; cultivated here in 1724, by Mr. Furber. Pursh says it is one of the most abundant and useful of its genus, in America, and grows in the middle States to an immense size. The adult leaves are nearly a fura long, deeply and elegantly pinnatifid; tapering and acute at the base; gradually dilated upwards: somewhat abrupt, though three-lobed, at the end; their lobes all entire, blunt, pointlefs, veiny; the upper surface green and shining; the under opaque and glaucous; not downy, as Linnaeus and Wildenow define them, except perhaps when young. Footstalks blunt, angular, half an inch, or more, in length. Fruit-footstalks twice as long, each bearing one or two, laterally selle, ovate acorns. Full an inch in length, with a short tuberculated cup. Michaux observes, that this Oak is preferred to all others in America, for building houses and ships; as well as for calks. The wood is so tough and pliable, as to serve for making baskets and brooms. The acorns are sweet, and Parkinson records that, in his time, the Indians were paid to obtain from them, by boiling, an oil which they used in cookery. A supposed variety, called jupefa, is figured by Michaux, in which the leaves are merely waved, not lobed; and green on both sides, though downy beneath. With this we are unaeeainted, as also with Wildenow's intermediate variety, called pufidaea.

70. Q. Ficiflua. Italian, or Small-prickly-cupped Oak. Linna.
QUERCUS.

Linn. Sp. Pl. 1414. Willd. n. 63. Ait. n. 22. (Phagus ecusius, mas et femina; Dalech. Hift. 5.)—Leaves ovate-oblong, tinmated, smooth; palaer beneath; segmentis bluntish; somewhat angular at the base. Fruit nearly leathery. Calyx scaly, hemispherical. Native of the south of Europe. Cultivated by Miller in 1739; chiefly in our gardens, flowering in May. Aiton. So little attention has been paid to this species by botanical writers, that we can find no certain description nor figure of it, except in Dalechamp. We do not pretend the plant intended in the first edition of the Hortus Kewensis be the true one; yet this seems what Willdenow meant in his Arctes, or Baumzucht, though he does not cite either that work or Furt. Kew. in his Sp. Pl. What Linnaeus briefly describes in his Mantissa, 460, under the name of Eufalus, seems to be Ceris, with which latter the description, copied by Willdenow, and the specific character extracted therefrom, well agree; but not at all with the original and authentic specimen of Eufalus in the Linnean herbarium. By this last alone can any one determine what Linnaeus had in contemplation, when he wrote both editions of Species Plantarum, and we shall here describe the specimen. The branch is angular, furrowed, and smooth. Leaves scattered, aggregate at the top, from two to three inches long, and, one and half at mull, in breadth; smooth and shining above; paler, rather glaucous, and almost equally smooth, beneath, with finely reticulated veins; tapering at the very base, but last above it dilated, angular, and in some measure cordate, as Dalechamp’s figures more distinctly shew. The summit is obtuse, and the margin cut unequally, on each side, into about five broad, blunt, entire, tooth-like serratures, or small lobes. Footstalks near an inch long, destitute of the long, linear, tufted, stipulate scales, or ramenta, found in Aegilops, Ceris, and Arcyria here mentioned. Young acorns axillary, nearly sepal, solitary or in pairs; the cups scaly, the size of small peas. Dalechamp represents the full-grown acorns about an inch long, embraced by an hemispherical scaly cup, about one-third that length. He says they are sweet and eatable, brought to table roasted by the Spaniards, as well as the rustic Italians, but sometimes found to affect the head, like dandle. The name Eufalus is derived by etymologyists from efeus, food, and is commonly taken for the Beech-tree, ordinary readers of Virgil’s Georgics not distinguishing one from the other; just as the Cicada of that poet has been vulgarly suppos’d the graftshopper. The Delphin edition of the Georgics has the above word Aesculus, as Linnaeus has adopted it, unwarrantably, for the generic appellation of the Horfe Chefnut; and the editors rightly observe, that some perfons confound it with Pagus, the Beech. Our P. Eufalus is most probably the Planus of Dioscorides, which he expressly says is a kind of Oak. See PAGUS.

71. Q. Robur. Common Britifh Oak. Linn. Sp. Pl. 1414. Sirn. Fl. Brit. n. 1. Engr. Bot. t. 1342. Woody. Med. Bot. t. 1. 126. Mart. Rufl. t. 10. var. pedunculata. (Q. pedunculata; Willd. n. 65. Ehrh. Arb. 77. Fl. Off. 168. Ait. n. 24. Q. foemina; Roth. Germ. v. 1. 408. v. 2. p. 488. Fl. Dan. t. 1180. Q. racemosa; Lamarck Dict. v. 1. 715. Q. cum longo pediculo; Bauh. Pin. 420. Q. hemeris; Dalech. Hist. 4. Quercus; Fouch. Hist. 229. Mart. Valgr. v. 1. 184. Duhm. Arb. v. 2. t. 47. Tabern. Kreuterb. 1374. Oak-Tree; Hunt. Engl. Sylv. 69, with a plate).—Leaves deciduous, oblong, smooth, dilated upwards; finules rather acute; lobes obtuse. Stalks of the fruit elongated. Nut oblong. Common in woods and hedges, throughout the more temperate parts of Europe, flowering in April. Nothing is more general in the woods and hedges of Britain, nor more important as an object of national culture. The tree is the most ornamental to our plantations and landscapes; the wood more useful than any other, for its hardness, toughness, and durability; the bark peculiarly valuable for tanning. The leaves are alternate, with short, or scarcely any, footstalks, obovate-oblong, smooth, irregularly finulate, with obtuse, rounded, pointed, entire, little (brows; their upper side of a rich shining green; the under paler, finely glaucous; the base somewhat heart-shaped, or auricled. Chyters, or rather fpikes, axillary; the male ones lax, pendulous, many-flowered, yellow; female on stalks an inch and a half or two inches long, composed of about three, laterally finulate, green flowers, fruited by a naked elongation of the common stalk. Calyx of the male nearly branched, bell-shaped, mostly five-cleft, with about ten flumes; of the female carious, scaly, downy, globose, at length hemispherical, woody, entire. German ovate. Style short, cylindrical. Stigmas three. Acorn elliptic-oblong, thrice the length of the cup. This being what Linnaeus, as well as British botanists, always considered as Quercus Robur, the superior quality of its wood, no where better understood than here, entitling it, above all others, to that appellation, we cannot, on any account, submit to the errors of Willdenow, or any other writer, who has been pleased to change the name; and we feel equal surprize and regret that the excellent editors of the new Hort. Kew. should, in this case at least, have carried their implicit conformity so far. We trufi they will hereafter correct themselves in this point, as well as in the barbarous name A trialicaria, retained by Willdenow, contrary to all propriety, for Dombeya. See that article.

72. Q. fultiflora. Selfis-fruited Oak. Salifb. Prodr. 392. Sm. Fl. Brit. n. 2. Engr. Bot. t. 1845. (Q. Robur; Willd. n. 64. Ait. n. 23. Lamarck Dict. v. 1. 717. Mart. Rufl. t. 11. var. fultilis. Q. fultilis; Ehrh. Arb. 87. Q. platyphyllus mas et femina; Dalech. Hist. 2. z. 3. Q. latifolias mas, que brevif pediculo et; Bauh. Pin. 419. Rail Syn. 440.)—Leaves on longif footstalks, deciduous, oblong, smooth; finules opposite, rather acute; lobes obtuse, Fruit felfile. Nut oblong. Native of woods and hedges, in the temperate parts of Europe; rather less common in England than the preceding, flowering in April or May. Professor Martin has rightly corrected Miller, who mentions the present as the common Oak of this country, and the former as rare. Why the German botanists, like Lamarck, take this for Robur, is difficult to understand, unless the measure originated in Inattention to the qualities, as well as history, of the trees. The wood of our fultiflora, in which name we gladly follow Mr. Salisbury, is of far less value than the true British Oak, and the importation of distinguishing the two species becomes, therefore, the more obvious. The leaves grow on longer footstalks, and are generally more equally and regularly pinnatifid. The female flowers, and the acorns, are almost perfectly felfile. In English Botany four fijmas are delineated; but we know not how far that character, which would be an excellent one, is confant.

73. Q. pubefcens. Downy-waved-leaved Oak. Willd. n. 66, excluding the reference to Fl. Brit. (Q. Robur lamargifala; Lamarck Dict. v. 1. 717. Q. Robur primus; Chl. Hist. v. 1. 18.)—Leaves oblong-ovate, falked, finulate, beneath; leaves obtuse, angular, wavy; somewhat heart-shaped and unequal at the base. Fruit nearly felfile. Native of France, Austria, Hungary, Taratary, and of the Val d’Aosta, Piedmont, in which last place it was reared by Mr. Davall. We have seen a tree of this...
this species, growing on the north lawn at Holkham, Norfolk, the feat of Mr. Coke, where it was planted by his ancestor, the earl of Leicester; but no British writer seems acquainted with the species in question, though unequivocally distinct. Willdenow judiciously says it is like his Robar, our *fijiflora*, but abundantly different, being of more humble stature, with smaller leaves, downy beneath, very hoary and white in the spring; somewhat heart-shaped at the base, and with smaller fruit. To this we would add, the leaves are remarkably undulated, especially in drying, and their upper surface is more or less befringed with very minute, scattered, hairy hairs. The fruit in Mr. Davill's specimen is quite fertile, either solitary, or in one instance accompanied by two abortive ones; in those from Holkham the female flowers are more or less elevated, three together, on a thick downy stalk. Hence perhaps Willdenow terms the fruit imperfect. The scales of the cup in both are downy, thin and flat, and coarsely imbricated.

A variety of this, with deeper segments, and of more humble growth, is Robur tertia, Clus. Hist. v. 1. 18. t. 1. Of this a specimen, erroneously named Ceris, and pinned to *Eucal.*, p. 75, above described, is preserved in the Linncean herbarium.

74. Q. atro-virens. Durm. Oak. Mart. Rul. t. 1. 12. (Q. alba; Sm. Fl. Brit. 1. 1027. Q. pubescens; Ait. n. 25, but not of Willdenow. Q. Robur nigra; Lamarck Dict. v. 1. 717. Chêne noir; Secondat du chêne. 3. t. 57.)—Leaves elliptic-oblong, flattened, finuated; downy and hoary beneath; lobes numerous, obtuse, even, and entire; base equal. Fruit fertile.—Native of France and the south of England, flowering in April and May. Prof. de M. Martin had his specimens from the New Forest, Hampshire, where it is known by the name of the Durm. Oak. The whole tree is well described by him as having much the air of a cherifruit, and being of freer growth than the true Robur; the bark lighter coloured and smoother; the wood not so strong, nor of so firm a texture. The leaves are less deeply, but more copiously, finuated, with five, six, or seven short lobes at each side; the under surface downy, and of a hoary grey, with purplish hairs. The foliation appears later than in either of our common Oaks, and lasts longer, sometimes the whole winter. *Acorus* fife, rather large. Lamarck's description, indicated above, agrees exactly with our *pubifera*, which, to which we add, the finuated of Secondat may belong, though we have not been able to consult his book. A more accurate study of this genus has led us to agree with our departed friend Willdenow, in distinguishing the Durm. Oak from our *fijiflora*, but he errs in referring to it his *pubifera*, and has led Mr. Aiton into the same mistake. Its leaves are more oblong, less deeply finuated, flat, not undulated; the under side whiter, with coloured veins. The fruit larger, and more decidedly fife.

75. Q. pubifera. Pyrenean Oak. Willd. n. 67.—

"Leaves oblong, pinnatifid, flattened; downy beneath; somewhat heart-shaped and unequal at the base; lobes obtuse, slightly toothed. Fruit flattened."—Native of the Pyrenees. The leaves are larger than in *fijiflora*, flattened, deeply finuated; densely downy underneath. *Footstalks* downy. *Acorus* four, fife, on one common elongated stalk. It differs abundantly from the *pubifera*, in having much larger leaves, finuated in a pinnatisect manner, very downy beneath, and flaked fruit. Such is Willdenow's account. We have seen no specimen. Can this be the above-mentioned variety of *pubifera*?

76. Q. segtina. Beech Oak. Lamarck Dict. v. 1. 725. Willd. n. 68. (Phellodrys alba angustifolia, folio ferrato; Dalech. Hist. 25.)—Leaves on short downy stalks, obvate, with numerous, uniform, shallow lobes; downy beneath; somewhat heart-shaped and unequal at the base. Fruit fertile.—Native of Spain and the south of France. Leaves small, an inch and half long, deciduous, obvate, very slightly finuated, or, more properly speaking, coarsely toothed, the lobes being very short, equal, and obtuse; the upper side polished and smooth, the under white and downy. *Footstalks* downy, Fruit fertile. Willdenow.

In the Linncean herbarium are specimens, gathered by Baron Altiroemer in Spain, which answer extremely well to the above description, and not amiss to the figure of Dalechamp, which Lamarck cites with hesitation. In these, however, the lobes, or teeth, are acute, and the upper surface covered with minute hairy hairs. There are also long, linear, recurved, ramiform *fife*, that are soon deciduous. We do not scruple to consider this as Lamarck's plant at least, and probably Willdenow's.

78. Q. ciliiflosa. Blunt-lobed Iron Oak. Michaux Querc. n. 1. t. 1. Pursh n. 25. (Q. stellata; Willd. n. 71. Ait. n. 26. Wangerb. Amer. 78. t. 6. t. 15.)—Leaves oblong, finuated, roughish on both sides; lobes obtuse; the upper ones dilated, abrupt, slightly divided. Calyx of the fruit hemispherical.—Found in most of the upland forests, from Canada to Florida, blooming in May. The tree is fifty or sixty feet high, spreading, its timber of great value for ship-building. The whitewash of the bark, as in *Q. alba*, causes both these species to be called White Oak by the Americans, who neverthelcss know how to distinguish their timber. The leaves of the presset are roughish beneath, with minute ruslly hairs, not hoary; and their upper surface appears to partake occasionally, as not always, of the same sort of pubescence. Their length is from three to five inches; the base wedge-shaped, spreading upwards into two smaller, opposite, rounded lobes, beyond which the *fif*; dilutes, suddenly and widely, into a pair of broad, slightly cloven, or emarginate, lobes, and, after another sudden contraction, ends in a terminal three-cleft one. The margin is entire throughout. *Footstalks* short, downy. *Acorus* three or four on a short stalk, of a middling size, scarcely exceeding our Dritish Oaks, elliptical, about half enclosed in the sealy cup.

79. Q. latifolia. Over-cup Lyrate Oak, Swamp-poll, or Water White Oak. Walt. Carol. 255. Willd. n. 72. Ait. n. 27. Pursh n. 28. Michaux Querc. n. 3. t. 4.—Leaves oblong, deeply finuated, smooth; much contracted in the middle; lobes acute; the upper ones dilated, angular, and abrupt. Calyx of the fruit globose, muricate, nearly covering the nut.—Native of swamps, from Carolina to Florida, and on the Mississippi; flowering in May. Purfe. Michaux lays, that though he always found this species in watery places, its growth, in a dry surfey-ground, exceeded that of more other species planted with it. He gives fifty or sixty feet as the height of the tree; Pursh from eight to fifteen only. The smooth fine-green leaves have more acutely-angular lobes than the foregoing, and are remarkably contracted about the middle. *Acorus* globose, nearly covered by the globalur prickly cup.
Quercus.

80. Q. macrocarpa. Large-fruited Oak, or Over-cup White Oak. Wild. n. 73. Pursh n. 26. Michaux
Querc. n. 2. 1. 2. 3.—Leaves oblong, lunate; downy
behind; terminal lobe very large, three-lobed, furfurated. Calyx of the fruit hemispherical, scaly, fringed with
bristles.—Found on dry flat or linnetone hills, in all the
countries to the west of the Allegheny mountains, flowering
in May. A large tree, whose wood, according to Pursh
and Michaux, is very excellent. The bark of the young
branches is corky. In wet situations the whole plant
is clothed, and becomes covered with lichens. The leaves
are a foot long, more truly and precisely lunate than those of
the last; but the specific name of the present is excellent,
the acorns being larger than those of any other known
American species. Their form is oval, their length two
inches, and they are half covered by the cup, several rows of
whole broad scales end in long bristles, making a rigid
fringe.

81. Q. oliviformis. Olive-shaped Mossy-cup Oak.
"Michaux Arb. v. 2. 32. t. 2." Pursh n. 27.—Leaves
oblong, smooth; glaucous beneath; deeply and uneq-
ually pinnatifid. Fruit elliptic-ovate. Calyx cup-shaped,
fringed."—Observed by Michaux on the banks of Hudson's
river, and in the western parts of New York; by Pursh in
Pennsylvania and Virginia, on iron-ore hills; flowering in
May. This is described as a large tree; folage hand-
some, somewhat resembling that of the last. We have not
examined either a specimen or figure. Willdenow does not
mention this species.

82. Q. crenata. Hairy-cupped Oak. Lamark Dict.
t. 12. (Q. Tournefortii; Wil. n. 72. Q. orientalis
latifolia, foline ad o Shawn pulchra incis, glande
maxima, cupula crenata; Tourn. Cor. 40. Voy. v. 2.
172.)—Leaves on long stalks, oblong, deeply pinnatifid; downy
behind; lobes lanceolate, blint, nearly entire. Calyx of
the fruit hemispherical, downy, blintly.—Gathered by
Tournefort in valleys and plains near Tocat, in Armenia.
Olivier says it is met with throughout great part of Asia
Minor and Syria. The timber is brought to the arsenal of
Constantinople, from the southern shores of the Black Sea,
and is also most commonly employed for the frame-work of
houses. The tree grows to a considerable height, and fur-
nishes excellent wood. This author, who takes the tree in
question for Q. Cerris of Linnaeus, may, possibly, confound
the real Cerris along with it, as Lamark, though not
without error, has combined them. Olivier's plate, how-
ever, very clearly represents the above plant of Tournefot;
and Lamark's excellent definition of the same, a variety
of his crenata, is abundantly sufficient to dispel it a species.
"Leaves very softly villous, deeply pinnatifid; their fig-
ments oblong, nearly simple, obtuse, somewhat pectinate;
(or parallel.) He says it is reported to grow wild in the
province of Angoumois, and is a tree of handsome aspect,
remarkable for its soft, downy, broad leaves, cut very
deeply into large segments, blunt at their extremity, often
simple, sometimes furnished with a few angles, or short
lobes, at their posterior margin. Acorns feline, their cup
briefly, as in the Burgundy Oak (Cerris). Tournefort's
specimens agree with the Angoumois Oak, and it is called,
by Lamark in a cultivated flat, near Godivillier. We
have seen no specimen, but the above accounts are sufficiently
clear to admit of no doubt. Olivier's plate represents the
leaves three or four inches in length, their segments about
an inch long, almost all simple and undivided, blint, enti-
tire, more or less dilatant, each making an angle with the
narrow linear border of the main rib. Foot-flanks slender, an
inch, more or less, in length, apparently smooth. Acorns
lateral, about an inch long, elliptical, obtuse, solitary, on
short simple stalks; the cups being somewhat yellow
brown, bristly, divided upwards and downwards, near half an
inch long. Nothing is exhibited, or described, concerning
the stipulae, which are very remarkable in the two following
species.

Wild. n. 75. Alt. n. 28. (Q. crenata a et z; La-
marck Dict. v. 1. 718. Q. halipheo; Julff. in Hort.
Ger. Cerris, Q. burgundiae, calye hepido; Bauh. Pin. 420.
Cerris Plini, grande glande; Lob. le. v. 2. 156. Dod.
1. 6, 7, 8.)—Leaves very few, short, oblong,
deeply and unequally pinnatifid; leafy beneath; lobes
laceolate, acute, somewhat angular. Stipulas longer than
the foot-flanks. Calyx of the fruit hemispherical, blintly.
—Native of France, Italy, and the Levant. Sometimes
cultivated in England, but not commonly. This is a tall
handsome tree, whose synonyms are much confounded by
old writers with Q. Aegillops, n. 68, and by more recent
botanists with the following. Its leaves are deeply pinnat-
tid in the manner of the foregoing; more or less unequa-
ally, but the lobes are more acute, pointed, and most general
angular, sometimes remarkably lobed or compound. The
under side differs essentially, in being neither downy nor
hoary, but rough with minute, feathered, tawny, blintly
hairs; the upper, which is of a darker green, and rather
finishing, is also occasionally roughish to the touch. Foot-
flanks rough, thick, hardly a quarter of an inch, sometimes
not a line, in length. Stipulae linear, acute, downy, from
half an inch to an inch long, permanent, accompanied by
an axillary tuft of similar, but smaller, scales. The acorns
we have not seen. They are represented feline, two or
three together, large, oblong, with an hemispherical cup,
which is frayed with long bristles, projecting in every di-
rection. They are said to be peculiarly bitter and astringent.
Lamark affirms, from his own observation, that the Q.
orientalis latifolia, glande maxim, cupula crenata, Tourn.
Cor. 45, scarcely differs in any respect from this. If so,
the term latifolia is not happily applied, unless Tournefort
had also noticed, as in our last, the deep divisions of the
leaves, which are full as remarkable in the present species.

84. Q. agilicata. Austrian Oak. Wild. n. 76. (Q.
Cerris; Hoff. Syn. 520. a et z. Alt. n. 28. Q. cri-
mina, cerris Linn.; Lamark Dict. v. 1. 718. Q. calye
hepido, glande minore; Bauh. Pin. 420. Cerris; Czit.
Hall. v. 1. 25, excellent. Cerris minoris ramulos cum flore;
Gen. Em. 1345, with Clusius's figure. Clusius Plini
more glande; Lob. le. v. 2. 156. Gen. Em. 1345. Aegi-
lops minora glande; Dod. Pemp. 831. Halipheo, Cerris
formans; Dachis. Hall. v. 1. 7.)—Leaves on longish
flanks, ovate-oblong, slightly but copiously furfurated;
downy and hoary beneath; lobes short, ovate, acute, enti-
ture. Stipulas shorter than the foot-flanks. Calyx of the fruit
hemispherical, blintly.—Native of Austria, Hungary, Carniola,
Italy, and other parts of the south of Europe, in lofty
mountainous places. It occurs not unfrequently in planta-
tions of exotic trees, both in France and England, being
generally mistaken for Q. Cerris, from which it is easily
be more certainly distinct. This tree is taller than the Com-
mon Oak, Q. Robur, and in favourable situations rises per-
pendicularly to a considerable height, as Clusius described
it, though Lamark says it is smaller, less handsome, more
twisted and knotty, than the last, as well as often hollow.
The wood is whiter, softer, and less valuable than Q.
Robur; the bark grey, tolerably even. Branches forming
a round
Leaves two or three inches long, acute, generally rounded and a little unequal at the base; their upper surface of a fine shining green, and nearly smooth; the under whitish, clothed with fine dents down; the margin, at each side, into four, five, or six, tolerably regular, rounded or ovate, acute, pointed, entire lobes, more or less deep, separated by round sinuses; the stalk of the leaf being left entire, of a considerable width. **Footstalks** near an inch long, downy. *Stipulae* as in the foregoing, but smaller and shorter, usually about half the length of the footstalks. **Acorns** like those of the luff, but smaller. The figures of *Lobel, Dodonaeus*, and *Ger. Emm. 1745*, do not well represent the leaves of this species, or indeed of the former: that of *Chiusus*, adopted by the editor of *Gerarde*, in p. 1746, is perfectly correct. The cuts of Dallechamp, both of one and the other, are insufficiently expressive, and very correct as to the footstalks. The lobes of neither of these species are quite pointless, but rather more pointed, as well as acute, than those of *Eftula*, n. 70.

We have thus added eight species of *Quercus* to Willelow's list. Those botanists who may take the trouble of following us with attention, will perceive that this valuable genus may require elucidation, particularly with respect to the European kinds; above all, the oriental kinds, none of which leaf, barely indicated by authors, we have been obliged to leave unexplained. Of the most common and important species, *Q. Rubra*, we have seen in Mr. Coke's woods at Holkham, some striking varieties, at least, whose distinctions and qualities are well worthy of examination. Two of these have shorter flower-stalks than the common *Rubra*, and one of them is three weeks earlier in coming into leaf than the other. The footstalks of both are longer than is usual in *Rubra*. How far a difference of quality in the wood may accompany these botanical distinctions, we must refer to the inquiries of those who are interested in, and have the means of investigating, so important a subject, which is indeed of the first economical, and even national, consequence. It is much to be wished that the species of the Norway Oak, so valuable for floors, on account of its straightness, and freedom from knots, could be determined. Perhaps these circumstances are owing to its being drawn up straight, with few branches, in its close native forests, and therefore it may not be specifically different from one or other of our own species. Michaux, and other writers on the American Oaks, have taught us, that the profusion of the leaves in this genus is of more specific importance than has previously been supposed, and we therefore have paid the more regard to it in discriminating some of the European kinds. The flowers, male and female, appear fill to demand more precise investigation and comparison, than they have any where received. S.

*Quercus*, in *Gardening*, furnishes plants of the forest, deciduous, evergreen, ornamental tree-kinds, of which the species cultivated are, the common oak-tree (Q. robur); the willow-leaved oak-tree (Q. phellos); the chubut-leaved oak-tree (Q. primus); the black oak-tree (Q. nigra); the red oak-tree (Q. rubra); the white oak-tree (Q. alba); the Italian or small prickly-cupped oak-tree (Q. coccifera); the great prickly-cupped oak-tree (Q. argilopa); the Turkey oak-tree (Q. coccifera); the evergreen or holm oak-tree (Q. flex); the holly-leaved evergreen oak-tree (Q. graminia); the cork-barked oak, or cork tree (Q. tuberc); and the kermes oak-tree (Q. coccifera).

Of the first there are several varieties; as with the acorns on long peduncles. This is found in the wilds of Kent and Sussex, where there are many large trees. The leaves are not so deeply sinuated, nor are they so irregular as in the common oak; but the indents are opposite; they have scarcely any footstalks, but quite close to the branches; but the acorns find upon very long footstalks. The timber of this oak is accounted better than that of the common oak, and the trees have a better appearance.

The broad-leaved evergreen oak, which grows upon the Apennines, and also in Spain and Portugal. The leaves are broader, and not so deeply sinuated as those of the common oak; they are of a lighter green on their upper side, and pale on their under; have very short footstalks, and their points are obtuse; the acorns have very long footstalks, which frequently fullain three or four in a cluster.

The dwarf oak, which grows in the south of France and Italy, and is a low bushy oak, rides but six or seven feet high, spreading out many slender branches the whole length. The leaves are oblong, and obtusely indented, about three inches long, and an inch and a half broad, standing upon slender footstalks; the acorns small, growing in clusters.

There are also many other varieties of common oak, which dealers in timber, and woodsmen, distinguish by their use, qualities, and accidents, and to which they give different names; but these being merely local, and not distinguished on permanent characters, it is difficult to ascertain them.

In the second species they distinguish two sorts; one of which is called the Highland willow oak, and grows upon poor dry land; the leaves are of a pale green, and entire, shaped like those of the willow tree; the acorns are very small, but have pretty large cups. The other grows in low meaf land, and rides to a much greater height; the leaves are larger and narrower, but the acorns are of the same size and shape. It is suggested, as probable, that their difference may be owing to the soil in which they grow. Martyn observes, that the latter becomes a large timber tree, and that there are said to be several varieties of it.

The third species has seemingly two varieties, one of which grows to a much larger tree than the other; but this may be occasioned by the soil, for the largest trees grow in rich low lands, where they become bigger than any of the North American oaks. The wood is not of a very fine grain, but it is very serviceable; the bark is grey and flaky; the leaves are five or six inches long, and two inches and a half broad in the middle, indented on the edges with many transverse veins running from the middle to the borders; they are of a bright green, and so nearly refeemle the chufet tree as scarcely to be distinguished from it. The acorns are very large, and their cups are short. The leaves of the other variety are not so large, nor so strongly veined; and the acorns are smaller, and a little longer. The different varieties are distinguished by the form of their leaves, which in the one is ovate, and in the other oblong.

The fifth has several varieties.

And in the ninth there are several varieties. The tenth species has likewise several varieties, differing greatly in the size and shape of their leaves; but these will all arise from acorns of the same tree: even the lower and upper branches have very frequently leaves very different in size and shape; those on the lower branches being much broader, rounder, and their edges indented and let with prickles; but those on the upper long, narrow, and entire. The leaves are from three to four inches long, and an inch broad near the base, gradually tending to a point; they are of a leaved green on their upper side, but whitish and downy on their under, and do not fall till they are shriveled off.
off by young leaves in the spring. The acorns are smaller than those of the common oak, but of the same shape.

The twelfth species has also two or three varieties; one with a broad leaf, a second with a narrow leaf, both evergreen; and one or two which call their leaves in autumn but the broad-leaved evergreen is the most common. The leaves of this are entire, about two inches long, and an inch and a quarter broad, with a little down on their under sides, on very short footstalks; these leaves continue green through the winter till the middle of May, when they generally fall off just before the new leaves come out, so that the trees are often alnmost bare for a short time. The acorns are very like those of the common oak.

The exterior bark forms the cork, which is taken from the tree every eight or ten years; but there is an interior bark which nourishes them, so that stripping off the outer bark is so far from injuring the trees, that it is necessary to continue them for; when the bark is not taken off, they seldom last longer than 50 or 60 years in health; whereas trees which are barked every eight or ten years will live 150 years, or more. The bark of a young tree is porous, and good for little; however, it is necessary to take it off, when the trees are twelve or fifteen years old, for without this the bark will never be good. After eight or ten years, the bark will be fit to take off again; but this second peeling is of little use. At the third peeling, the bark will be in perfection, and will continue so for 150 years; as the cork is taken from old trees. The time for stripping the bark is in July, when the second sap flows plentifully; the operation is performed with an instrument like that which is used for distarking the oak.

It is from the last species they collect the kermes, or scarlet grain, a little red gall, occasioned by the puncture of an insect called meacazillus. With this the ancients used to dye cloth of a beautiful colour.

Method of Culture.—These trees are all capable of being raised from the seed or acorns, which, in the common oak, should be gathered in autumn when quite ripe, just as they drop from the trees; but those of most of the foreign oaks are generally procured from abroad, and sold by the seedmen.

All the acorns should be sown as soon as they are obtained as possible, as they are apt to sprout if they remain long out of the ground; and for their reception a spot of light ground in the nursery should be prepared by digging or ploughing, dividing it into four feet wide beds, in which the acorns should be sown, either in drills, two inches deep, in five or six rows lengthwise of the bed; or rake the mould off the bed, the depth of two inches, into the alleys; then sowing the acorns all over the surface, about two or three inches apart, press them down with the spade, and spread the earth evenly over them two inches thick. When they come up in the spring, they should have occasional waterings and weeding; and when the plants are one or two years old, it is proper to plant them out in nursery-rows: this may be done in autumn, winter, or early in the spring, taking them carefully up out of the feed-bed, shortening their perpendicular tap-roots, and trimming off any lateral shoots from the stem, leaving their top perfectly entire; then planting them in lines two feet and a half asunder, and fifteen or eighteen inches in the rows, where they should stand, with the usual nursery care, till of a proper size for final planting out either as forest trees, or for ornament, training them up as full standards, with clean straight items, and with their tops still entire.

But in raising the striped-leaved varieties of the common oak, and any particular variety of the other species, it should be by grafting, (as they will not continue the fame from seed,) which should be performed upon any kind of oaking rocks raised from the acorns, and trained for standards, as in other kinds.

With respect to the final planting out, it may be performed in all sorts of deciduous oaks any time in open settled weather, from November till February or March; and in the evergreen kinds in October, November, or the spring; and in a mild open season in any of the winter months.

When the trees of all the sorts are from about three or four to six feet stature, they are proper for being planted out for good; though, as forest or timber trees, it is better to plant them out finally while they are quite young, from two to three or four feet in height; or when planted immediately from the feed-bed, where they are to remain, it may be advantageous, as the very young oaks root more freely than older trees, and take a freer growth. Tholc designed as forest or timber trees should be planted in large open tracts of ground, to form woods, placing them in rows only from four or five to ten feet asunder, and from two or three to five or six feet in the rows, to allow for a gradual thinning. But perhaps the best method of all for raising them, as timber trees, is from the feed, by fowing or setting the acorns. See Plantation and Planting.

Sometimes, indeed, large plantations of these trees, for woods, are raised by sowing the acorns at once in the places where they are to remain; it being generally found that the trees raised at once from the acorn, from their not being checked, much outstrip the transplanted trees in their growth. The method of performing it is this: the ground being prepared by good ploughing and harrowing in the autumn, having procured a proper quantity of acorns, draw drills across the ground four feet asunder, and two inches deep, dropping the acorns into them six or eight inches asunder, allowing for falling and thinning, covering them in evenly with the earth the depth of the drills; or, instead of drilling them in, they may be planted with a dibble the same depth and distance.

The general management of these trees in woods, or timber plantations, is the same as directed for forest trees in general. See Plantation.

All the above sorts of trees may be employed to diversify large ornamental plantations in out-grounds, and in forming clumps in spacious lawns, parks, and other extensive open spaces: the evergreen kinds, in particular, have great merit for all ornamental purposes in pleasure-grounds and plantations. And all the larger growing kinds, both deciduous and evergreens, are highly valuable as forest trees for timber; but the first sort claims precedence as a timber tree, for its prodigious height and bulk, and superior worth of the wood.

In planting any of the species for ornament or variety in large pleasure-grounds, some may be dispoled in affemblage in any continued plantation, some in clumps, and others singly.

All the different sorts of the oak will succeed in any foil of a middling quality, where the exposure is not unfavourable; but to the most advantage, where the land is of a loamy nature: they, however, thrive tolerably in those soils which are of a gravelly, sandy, or clayey description.

Besides the great value of these sorts of trees for the utility and durability of their wood, as timber, for the purposes of ship-building, house-building in stone, parks, palings, plots, railings, and a variety of other strong uses; they, in many of the kinds, afford considerable additional advantage.
advantage by their produce in bark, for the use of the tanners and cork-cutters, in tanning leather, and being made into cords; after the manner of which, it is also much employed in gardening, for the forming of hard hot-houses, in raising tender hot-houfe exotic plants: as well as in their annual crops of acorns, as an excellent food for the keeping and fattening of swine, deer, and some other animals.

Quercus, in Planting, a classical term sometimes applied to the oak-tree in nursery collections, intended for this sort of application. See Oak-Tree.

Quercus Marina, the Sea-Oak, in Botany, the name of one of the broad-leaved dichotomous sea-faules.

It is not agreed, among the late botanists, what was the Sea-oak of Théophrasus; and the most ancient botanists, Clusius and Celsispinus, suppose it to have been a species of the shrubby coralline; but that seems by no means to have been the case, since Théophrasus says his sea-oak had a long, thick, and flaky leaf, whence we may much more naturally conclude it to have been of the focus clafs.

Quercy, in Geography, a province of France before the revolution, in the government of Guinée; bordered on the E. by Rouergue and Auvergne, on the S. by Upper Languedoc, on the W. by Perigord and Agenois, and on the N. by Limosin: it contained two bishoprics, viz. Caors and Montauban. The air is good, and the land is fertile; its capital was Cahors. It now constitutes the department of the Lot.

Quereiva, in Ornithology, the purple-throated chatterer of Latham, a species of Ampelis.

Querela, Quarrel, in Law, denotes an action, or declaration, preferred in any court of justice. See Quarrel.

In an action where the plaintiff is called querens, i.e. complainant, his brief, complaint, or declaration, is called querela.

Querela Audita. See Audita.

Querela coram rege et concilio, a writ by which one is called to justify a complaint of a treafus made to the king himself, before the king and his council.

Querela Duplex. See Double Quarrel.

Querella, En gravi. See En gravi, &c.

Querenghi, Antonio, in Biography, a man of letters, was born at Padua in 1546. He displayed, at an early period of his life, a decided attachment to literature; he wrote verses before he was twelve years of age, and soon became dillinguished by his deep knowledge of the languages, civil laws, and the philofophy that was taught at that period. For some time he applied himself to theology, and made considerable proficiency in it. He next went to Rome, where he entered into the service of several cardinals, and at length became secretary of the facred college, in which capacity he was present at the election of five popes. Clement VIII. conferred upon him the canonry of Padua, which occasioned him to reside in that city, but he returned to Rome in the pontificate of Paul V., by whom he was promoted to some offices of trust. He died at Rome in 1613, at the age of 87. He was a man of various and extensive literature, and was much regarded by the learned of the time in which he flourished. His writings were numerous, and comprehended the sciences and polite literature. He is chiefly known to posterity by his poems, which are correct and elegant, but by no means animated. Moretti.

Queretano, in Geography, a town of Mexico; 89 miles N.W. of Mexico. N. lat. 20° 25'. W. long. 101° 36'.

Querfaa, in the Materia Medica of the Arabians, a name given by Aviceena and others to cinnamon, when gathered with the wood of the young branches.

It was a common practice in the early times not to strip the small bark from medicinal trees, but to cut off the little boughs, and use the bark and wood together. This the Greeks called xylo cinnamomeum, or woody cinnamon; and the Arabians, guerfaa, quefa, or kref.

Querfurt, in Geography, a town of Saxony, situated on the little river Weite, unimportant in itself, but having large suburbs; the number of houses is estimated at upwards of 500. The old castle belonging to it stands on a hill, and it has likewise a superintendency; 16 miles S.W. of Halle. N. lat. 51° 23'. E. long. 11° 45'.

Eff. Ch. Calyx of five leaves. Corolla none. Capsule of one cell, with one seed.

Obf. Linnaeus remarks, that this genus differs evidently from Minuartias, see that article, in having a folialy seed.

Q. canadensis, figured by Gartner, is removed hence by Michaux to the genus Angelia, which belongs to a different natural order, the Holarcina of Linnaeus, and has a capsule defrivate of valves. Gartner indicates its close affinity, except in number of glumes, to his Paronycha, see that article. Michaux and Pursh afford that its glumes vary from two to five.

1. Q. hispanica. Spanish Queria. Linn. Sp. Pl. 132. Wildl. n. 1. Att. n. 1. Loefl. 48. 83. Que. Pl. Elpan. v. 6. 667. t. 15. f. 2.—Flowers crowded into a tuft.—Native of sandy grounds in Spain. Seeds were sent to Kew, in 1800, by the late marchioness of Bute. The plant is a diminutive hardy annual, flowering most part of the summer. Root fibrous. Whole herb whitish, brittle, one or two inches high, with several leaves, round, rather downy, slightly redaith flem. Leaves opposite, feline, awl-shaped, three-ribbed, curved to one side, rather longer than the joints of the stem. Head of fowers oblong or quadriangular, densely dichotomous, easily breaking off from the stem. Braches opposite, awl-shaped, recurved, and hooked, easily catching hold of the coats of animals. Flowers very minute.

QUE

quaternis, caule dichotomo; Gron. Virg. ed. 1. 14. Any-
chlia dichotoma; Michaux Boreal-Amer. v. 1. 113. Pursh
v. 1. 176.)—Flowers solitary, stem forked.—Native of dry
lime-rite hills, from New York to Kentucky, flowering
from June to August. Introduced at Kew, in 1806, by
his royal highness the Duke of Kent, according to Mr.
Aiton, who marks it as a hardy biennial. Linneus and
others make it perennial; which the appearance of the plant
contradicts. The root is small, tapering, with a few pale
fibres. Stem solitary, near a span high, round, jointed,
smooth, reddish, erect, leaf: simple below; repeatedly
subdivided, forked and spreading, above; the branches di-
varicating, capillary, leafy, many-flowered. Leaves oppo-
site, on short stalks, obovate, entire, smooth, from one-
fourth to three-fourths of an inch long, covered on both
sides with reddish dots, which become prominent as the
leaves dry. These dots, Linneus says, disfigure by culture.
Stipules two at each side, membranous, acute. Flowers
very small, axillary or lateral, green, on short stalks.
Calyx-leaves concave, or vaulted, below the point.
Stamens, according to Michaux, always five in the wild
plant; in the cultivated one often but two. Linneus juitly
points out the resemblance of this herb, at first fight, to
Linum catharticum; but its strict affinity to Helichrysum, Poly-
genum, &c. is far more striking, as well as its total unlike-
ness to the original Queria; so that there can be no doubt
of the neceffity of removing it from the present genus,
whether the Anychia of Michaux be permanently established
or not.

3. Q. trichotoma. Three-forked Queria. Thunb. in
Bern. of the Linn. Soc. v. 2. 329. Wild n. 3. (Rubia
fipicis ternis; Thunb. Jap. 357.)—Flowers racemose. Stem
triply forked.—Native of Japan.—Herb with widely spreading,
thread-shaped, smooth branches. Leaves opposite, on
very short stalks, ovate, acute, nearly entire, smooth, widely
spreading, as long as the finger nail. Clusters axillary,
three; two opposite, one terminal, composed of three or
four pair of opposite, minute, decussate flowers. To
this description Thunberg adds:—"Corella cylinncr. Fruit
inferior, oblong, smooth."—This must be altogether a
mistake, if the plant has any pretensions to be reckoned a
Queria. Having seen no specimen, we leave the matter as
we find it. The genus before us must probably depend on
the first species only; and whether the character of the folli-
cacyr, by which one it stands distinguished from
Minuartia, be sufficient, there being the strictest conformity
in habit and every other particular, we feel much inclined to
doubt.

QUERIGU, in Geography, a town of France, in
the department of the Arriége, and chief place of a canton,
in the district of Foix; 23 miles S.S.E. of Taraces. The
place contains 809, and the canton 2483 inhabitants, on a
territory of 1242 kilomètres, in seven communes.

QUERIMBA, a cluster of islands, deriving its name
from the principal, in the Indian sea, near the coast of
Africa; fertile in dates, oranges, grapes, and other fruits
and legumes. The pastures feed great numbers of large
and small cattle, and the coasts abound with fish. These islands,
when first discovered by the Portuguese, were inhabited by
Arabians; but at present they are chiefly occupied by the
defendants of Portuguese. S. lat. 12° 20'- Allo, a
country of Africa, bordering on the coast. S. lat. 9° to
13°. —Allo, a river of Africa, which runs into the Indian
sea. S. lat. 12° 20'.

QUERKEINE, or Kerkeine, two islands in the
Mediteranean, near the coast of Tripoli; one of them
about ten miles long and five wide, anciently called "Cer-
Vol. XXIX.
the father of Louis XVI., and by the whole court. After the dauphin had undergone the small-pox, the king presented him with letters of nobility, unfilicted, as a mark of his esteem. He was appointed also first physician in ordinary to his majesty. He was a member of the Academy of Sciences, of the Royal Society of London, &c. Notwithstanding his long life, and his courtly favour, as well as extenuative employment, he died poofelled of little fortune, his liberality to his friends having prevented him from accumulating money. His death took place at Verailles, in December, 1774, at the age of eighty.

This able and indefatigable man left several works, which bear the stamp of considerabte research, clear and methodical views, and acute observation, mixed, however, with some disposition to hypotheses. His first essay on blood-letting, already mentioned, was published in 1730, under the title of "Observations sur les Effets de la Saignée, avec des Remarques critiques sur la Pratique de l'Homme;" and a second edition, considerably enlarged, was printed in 1750. But in the mean time he published another work, entitled "L'Art de Guérir par la Saignée," Paris, 1736, in which he recommends blood-letting in many diseases. In the same year appeared his "Éléments Physiques de l'Economie Animale," in two volumes, 12mo., which was reprinted in 1747, in three volumes. This work, however, was deemed very imperfect by Haller, and is in fact characterized by a love of hypotheses, rather than by the details of experience and observation. In 1743, his "Précis des Mémoires de l'Académie de Chirurgie," gained him considerable applause, as a work of literary research. In 1744 he published his "Recherches critiques et historiques sur l'Origine, fur les divers États, et par les Progrès de la Chirurgie en France," which called forth some reply on the accuracy of the historical statements. His other publications were entitled, "Traité de M. de la Peyronie du 18 Avril, 1747;" "Examen impartial des Controverses des Médecins et des Chirurgiens de Paris," 1748, 12mo.; "Mémoire présenté à l'Académie des Sciences, de Paris, où l'on examine la Saignée de l'Ancienne Législation sur l'Était de la Chirurgie en France," 1749; "Traité de la Supputation," 12mo.; and "Traité de la Garganture," 12mo.; all in the year 1749. And lastly, his "Traité des Fièvres continues," 1753, in two volumes, 12mo. Eloy Dict. Hilk. de la Médecine.

QUESNE, Abraham du, an able French naval commander, was descended from a noble family in Normandy. He was born in 1610, and was brought up to the sea-service under his father, who gave him the command of a vessel when he was only seventeen years of age. In 1637 he was present at the attack of the islands of Sainte Marguerite, and in the following year contributed greatly to the defeat of the Spanish forces before Gattori. He was afterwards in various actions on the coast of Spain. In 1644 he went to serve in Sweden, and was promoted to the rank of vice-admiral of the Swedish fleet. In this station he had a command in the famous battle in which the Danes were entirely defeated, and his vessel was one that was boarded and took the enemy's admiral ship. On his return to France he commanded a squadron sent to the expedition against Naples. The French navy being in a low state on account of the minority of the king, he fitted out several ships at his own expense in 1650, with which he sailed in the reduction of Bordeaux, which had revolted, and was aided by a Spanish fleet. In 1656 he had the glory of being opposed to the great De Ruyter. The Spanish and Dutch fleets had united to prevent the French from succouring the inhabitants of Messina, but Du Quefne, after a desperate fight, succeeded in entering the port. He was also engaged with De Ruyter when the latter was mortally wounded. Du Quefne obtained a more glorious and decided success in another engagement with the Spanish and Dutch fleets at Palermo, when, by means of his fire-ships, he destroyed twelve large ships of the enemy, and thus procured for his king the sovereignty of the Mediterranean. In 1652 he was sent with a fleet to awe the piratical states of Barbary, which had committed depredations on the French coasts, and in the following year he failed to Algiers, and bombarded the town with such fury as nearly to lay it in ruins. In the following spring the admiral anchored before the city, and did not leave it till he had destroyed almost all the buildings, with the whole of the shipping and fortifications, the consequence of which was they were obliged humbly to sue for peace. He struck terror into the fleets of Tripoli and Tunis, which were likewise compelled to purchase peace with France by submission. He performed other great and important services for his sovereign, but the remuneration due to him on account of all he did was impeded by his firm attachment to the reformed religion in which he was bred, and which the bigotry of the king regarded as criminal. He received, however, the royal gift of a fine estate, which was erected into a marquisate, and gave him a title; and on the repeal of the edict of Nantes, he was the only person exempted from its penalties. This great hero, one of the chief boasts of the French navy, preferred an extraordinary degree of health and vigour, notwithstanding the many wounds he had received, till his death in 1668, when he had attained to the 78th year of his age. He left a son, of whom we shall say a few words.

QUESNE, Henry du, was born in 1622, and at the age of fourteen he entered the French navy, and served with great distinction under his father. He was present at the bombardment of Algiers in 1663, and negotiated the peace of Tunis. At the period when the highest prospects in his profession lay before him, his attachment to the Protestant religion caused him, at the repeal of the edict of Nantes, to quit his country and the service, but he refused with indignation the offers that were made him to take a command in the armies of its enemies, and retired to Switzerland. His high reputation raised him to great credit with the Protestant powers, which he employed in engaging them to undertake the protection of his persecuted brethren; and through his means a great number of victims of the most cruel intolerance procured their liberation from the galleys. In 1701 he told his estate in Switzerland, and retired to Geneva, of which he was admitted to the citizenship. Here he died in 1723, respected alike for his learning and piety. As an author he had taken a considerable share in the version of the New Testament published by the pastors of Geneva, and he was author of a work entitled "Réflexions Anciennes et Modernes sur l'Eucharistie."

QUESNE, Fort du, in Geography. See Pittsburg.

QUESNEL, Pasquier, in Biography, a French priest of much celebrity, was born at Paris in the year 1634. Having completed his education, and being admitted a member of the congregation of the oratory, he took priest's orders in 1659. From this time he devoted himself, with great diligence, to the study of the Scriptures, and of the fathers, and to the composition of books in practical piety. At the age of 28 he was appointed first director of the institution belonging to his order at Paris. The first of his publications was entitled "Moral Réflexions upon the Gospels." After this he was employed in preparing for the press a new edition of "The Works of St. Leo," in two volumes, 4to., in which he has given a vast number of notes that
that reflected great honour on the learning of the editor. Its
value was enhanced, in the judgment of his countrymen, by
his introducing into it an able defence of the sentiments of
the Gallican church, in opposition to the pretenions of
the church of Rome. This circumstance gave great offence to
the papal government, and the edition was condemned in the
following year at Rome. On account of his attachment to
father de Sainte-Marthe, general of the oratory in France,
he was obliged to quit his diocese, and from other unpleasant
circumstances he thought it right to withdraw privately from
France into foreign countries. He took refuge at Bruxels,
where he continued his “Moral Reflections” on the acts of
the apostles, and the epistles. This, with his former work,
he published in 1687. He afterwards revised and made addi-
tions to the former work on the Evangelists, and printed
an uniform edition of the whole in 1693 or 1694, in four vols.
8vo. In the year 1703 the Jesuits, always impenial to the
rights and liberties of mankind, and who, to the utter dis-
grace of the present period, have been just re-established in
their powers, availed themselves of their influence with an
ignorant and bigotted king of Spain, to obtain an order for
the arrest of father Quefnel, who was now thrust into a
dungeon belonging to the archiepiscopal palace at Bruxels.
From this situation he was unexpectedly delivered in less
than four months by the ingenuity of a Spaniard, who con-
trived to open a passage through the walls of the prison suffi-
ciently large for his escape. Having thus obtained his li-
bery, he made the best of his way to Holland, where he
published several pieces in vindication of himself and writings
from charges preferred against both before the ecclesiastical
court of Mechlin, and the sentence of condemnation pro-
nounced by the archbishop. In the year 1705 the enemies
of Quefnel applied to the pope Clement XI. for the con-
demnation of the “Moral Reflections,” to which he acceded,
although he had some years before expressed his de-
cided approbation of them, and even wished to engage the
author to come to refit at Rome. Such, however, was
the pontiff’s insufficiency, that he issued a decree which con-
demned the “Moral Reflections” in general, but with-
out specifying any particular doctrines which merited such a
sentence. At length, at the instigation of the Jesuits,
eager in the cause of persecution, Lewis XIV. joined himself
against Quefnel, and applied to the pope for a more definite
decree; his holiness, for so the most wicked as well as most
virtuous of the popes have ever been denominated, in con-
sequence of this application, established a congregation of
cardinals, prelates, and divines, to enter into a particular
examination of the doctrines and maxims which Quefnel had
advanced. That his work might not be condemned without
any efforts on his part to vindicate it from the accusations of
his enemies, our author wrote, on this occasion, two
letters to the pope, which were safely conveyed to Rome,
but Clement did not deign to give a reply. State policy
had already determined what measures he should adopt, and
after the sittings of the congregation were ended, he issued
the celebrated bull Unigenitus, in September 1713, which
pronounced a sentence of condemnation upon 101 proposi-
tions extracted from the “Moral Reflections.”

Father Quefnel spent the last years of his life at Amster-
dam, where he formed some Janifetiff churches, and published
his apologetic and controversial pieces against the bull Uni-
genitus, and its abettors. He died in 1719, in the 86th
year of his age. Independently of his “Moral Reflections,”
he was the author of several other works of high reputation, of
which we may mention, a treatise on “Predetermination
and Grace,” in four vols. 12mo, under the fictitious name of
sieur Germain; and “The Discipline of the Church deduced
from the New Testament,” in two vols. 4to. A list of
this author’s works may be seen in Moreti.

QUESNEL, FRANCOIS-DU, called the Fleming, an ex-
cellent sculptor, was born at Bruxels in 1594. He learned
his art under his father, who was a sculptor, and at an early
age displayed so much ability, that the archduke Albert gave
him a pension and sent him into Italy. After the death of
that prince, he was patronized by the countable Colonna;
and the celebrated Poullin advising with the countable at the
same time, the two artists contracted an intimate friendship,
and studied together. Quefnel formed himself upon the
taste of the ancients, and chiefly excelled in making bas-
reliefs and models in a small size, representing cupids and
children, to which he gave singular grace and delicacy. He
employed himself several years on a marble fountain, for
the chapel of Loretto, in which he imitated the genuine beauties
of the antique. When the canopy of St. Peter’s was
finished, pope Urban VIII. ordered four colossal statues to
be placed in the niches. That of St. Andrew was given to
Quefnel, and although one of his competitors ventured to
affirm that he would only produce a great child, yet when
the figure was completed, it entirely effaced his own per-
formance. Notwithstanding the talents of this artist, which
were united to much perseverance and industry, he could
barely earn a subsistence, and was in a very low state of
health and spirits, when, in 1642, Lewis XIII. engaged
him as his sculptor, and as the head of an intended school
for that branch of art, at a very liberal salary. This change
of fortune he was unable to bear, and as he was on the point
of quitting out, he sunk into a melancholy derangement, from
which he never recovered. His death, which happened at
Leithorn in 1648, has been imputed, but probably on in-
sufficient evidence, to poison, administered by the hand of
a brother with whom he lived on very bad terms. He was
mild in his manners, but of a reserved disposition. His re-
putation is chiefly founded upon the exquisite softness which
he gave to marble, and the peculiar grace and beauty of his
infantile groups, finished with perfect anatomical exactness.

QUESNEL, LE, in Geography, a town of France, in
the department of the North, and chief place of a canton,
in the district of Avesnes. The place contains 15,047
inhabitants, on a territory of 9099. That of St. Andrew was
finished, pope Urban VIII. ordered four colossal statues to
be placed in the niches. That of St. Andrew was given
to

Quefnoi, in Geography, a town of France, in
the department of the North, and chief place of a canton,
in the district of Avesnes. The place contains 15,047
inhabitants, on a territory of 9099. That of St. Andrew was
given to

Quefnel, and although one of his competitors ventured to
affirm that he would only produce a great child, yet when
the figure was completed, it entirely effaced his own per-
formance. Notwithstanding the talents of this artist, which
were united to much perseverance and industry, he could
barely earn a subsistence, and was in a very low state of
health and spirits, when, in 1642, Lewis XIII. engaged
him as his sculptor, and as the head of an intended school
for that branch of art, at a very liberal salary. This change
of fortune he was unable to bear, and as he was on the point
of quitting out, he sunk into a melancholy derangement, from
which he never recovered. His death, which happened at
Leithorn in 1648, has been imputed, but probably on ins-
ufficient evidence, to poison, administered by the hand of
a brother with whom he lived on very bad terms. He was
mild in his manners, but of a reserved disposition. His re-
putation is chiefly founded upon the exquisite softness which
he gave to marble, and the peculiar grace and beauty of his
infantile groups, finished with perfect anatomical exactness.

QUEST, or QUESTO, an inquisition, or inquiry, made
upon oath of an impaneled jury. See Inquest, and
Jury.

The word is formed from the French quête, search; of the
Latin questum, a thing sought.

QUEST, in Hunting, the seeking out of hounds, or the
venting and winding of spaniels. See Hound.

QUESTEMBERT, in Geography, a town of France,
in the department of Morbihan; five miles W.S.W. of
Rochfort. The place contains 3668, and the canton 12,118
inhabitants, on a territory of 2574, in nine communes.

QUESTION, QUESTIO, in Logic, &c. a proposition,
whose truth a person being inquisitive about, proposes by
way of interrogation to another.

Logical questions are variously distributed; the ordinary

M m 2 division
division is into first or primary questions; as, Quis est? What is such a thing? And secondary, which arise out of the former; as, Hoc est?

QUESTION. Quodlibetical. See Quodlibetical.

QUESTION in Law. The quæstio de jure is generally to be distinguished from the quæstio de fato.

QUESTION is also sometimes used for torture; which fee. QUESTO-MEN, persons chosen yearly in each ward, to inquire into abuses and misdemeanors, especially such as relate to weights and measures.

QUESTO-Men, in Ecclesiastical Law. See SIDESMEN.

QUESTOR, QUESTOR, formed a quareno, seeking, searching, or collecting the revenues of the state, an officer in ancient Rome, who had the care of the public treasure.

The quæstorship, quæstoria, is very ancient, as having been established under the kings, probably in the time of Romulus or Numa, or at least under Tullius Hostilius. Tacitus (Annal. xi. 22) says, that the first quæstors were elected by the people, 64 years after the foundation of the republic; but he is of opinion that they had, long before that period, been annually appointed by the consuls, and even by the kings. But this obscure point of antiquity is contended by other writers. Dionysius and Livy date the original of quæstors about A. U. C. 269. Plutarch refers the institution to the time of Valerius Poplicola, when he allotted the temple of Jupiter for the treasurers, and granted the people the liberty of choosing two young men for the treasurers. Afterwards, viz. A. U. C. 332, two others were created to take care of the payment of the armies abroad, of fowling the plunder and booty, &c. for which purpose they generally accompanied the consuls in their expeditions; and were distinguished by the name of peregrini from the other quæstors, who assumed the title of urbani. This number continued till the entire conquest of Italy; and then, A. U. C. 439, it was again doubled. The four that were added redivid with the proconsuls and praetors, in the provinces, where they were employed in regulating the taxes and customs due to the state.

In the time of the republic, the senate appointed quæstors in each province, to assist the proconsuls, as lieutenants or treasurers, in the administration of the revenues; but, under the emperors, there was properly but one quæstor, or treasurer-general of the empire; those other inferior or subordinate quæstors were then called ailiates of the quæstor, adjunctes quæstoria.

The quæstor's office was originally confined to the army. They paid the soldiers, and took charge of monies coming by spoil and plunder, &c.

At length there were new ones erected to reside in the city, and to receive the public money, taxes, tribute, &c. Their number was increased as the empire increased. Sylla augmented it to twenty; Julius Cæsar to forty; some being nominated by the emperor, and the others by the people. Tacitus (Annal. xi. 22) seems to consider twenty as the highest number of quæstors; and Dio (lib. xiii, p. 174) intimates, that if the dictator Cæsar once erected forty, it was only to facilitate the payment of an immense debt of gratitude. Under succeeding emperors their number was not fixed. Of these, two were appointed for the city, to take care of the public treasurers, and to keep the laws and decrees of the senate; the others pertained to the provinces and the armies.

The quæstorship was the first office which any person could bear in the commonwealth, and might be undertaken at the age of twenty-four or twenty-five years. Accordingly, the quæstorship was called the first step of honour, and the quæstors, who were generally employed in the provinces abroad, assigned to them severally by lot, no sooner returned from their provincial administration than they took their places in the senate; and from that time forward, from the rank of equites, or what we commonly call knights, became senators for life.

The youth and inexperience of the quæstors, who entered on that important office in the 25th year, engaged Augustus to remove them from the management of the treasury; and though they were reëlected by Claudius, they seem to have been finally dismissed by Nero. In the provinces of the imperial division, the place of the quæstors was more ably supplied by the procurators, or, as they were afterwards called, "rationalers." But in the provinces of the senate we may fill discourse a series of quæstors till the reign of Marcus Antoninus. From Ulpian we may learn, that under the government of the house of Severus, their provincial administration was abolished; and in the subsequent troubles, the annual, or triennial elections of quæstors, must have naturally ceased.

There was also another kind of quæstors, called quæstores particulariores, whose office was to enquire into, and take cognizance of capital crimes, after the consuls had denied this privilege.

QUESTOR sacri palatii, or of the sacred palace, was one of the chief dignities under the emperors of Constantinople.

It was this quæstor that subcribed the receipts of the emperor, and the answers to the petitions and supplications presented to him. He also drew up and signed the laws and constitutions which the emperor thought fit to publish; and took care of the administration of justice.

Some compare his function to that of our lord high chancellor. It was usually one of the jurists that was charged with this office; it being required, that he should know the laws of the empire, be able to prefer and see them executed, and judge of causes brought by way of appeal before the emperor.

Constantine was the first who erected quæstors of the sacred palace.

QUESTUS, or QUESTUS. See QUESTUS.

QUESTUS est nobis, a writ of nuisance, which, by Stat. 15 Edw. I. lies against him to whom a houfe, or other thing, that breeds a nuisance, is defended, or abated; whereas before that statute, the action lay only against him who first levied, or caused the nuisance, to the damage of his neighbour.

QUETIE, James, in Biography, a learned French Dominican monk, was born at Paris in the year 1618. He embraced the monastic profession among the preaching friars when he was not more than 17 years of age, and having completed his philosophical course at Paris, he was sent by his superiors to Bordeaux, where he studied divinity, and received priest's orders in 1648. He lived a great age, exercising his talents in various ways, and died in the year 1698, highly respected for his great erudition, his extensive knowledge, and his virtues. He published a new edition of the "Summa Theologiae" of Aquinas, in three vols. folio, with notes. He did the same by a work entitled "Concilii Tridentini Canones." He was editor of "The Spiritual and Aesthetic Letters of Savonarola;" and he published, with his own notes, "The Life of Savonarola," from the Latin of John Pius, count of Mirandula, with considerable additions. He wrote the preface to "The Letters of Peter Morin," which he published from the author's manuscripts; as he also did his treatise "On the good Life or Abuse of the Sciences." He was author of a considerable part of the work.
work entitled "Scriptores Ordinis Praedicatorum, cum notis Históricis,” which was completed by Father Échard.

QUÉTREVILLE, in Geography, a town of France, in the department of the Channel; six miles S. of Con-
tances.

QUETTEHOU, a town of France, in the department of the Channel, and chief place of a canton, in the dis-
trict of Valognes; nine miles N.E. of Valognes. The place contains 1,921, and the canton 14,956 inhabi-
tants, on a territory of 150 kilometres, in 17 communes.

QUETTENBRUN, a town of Austria; eight miles E. of Laab.

QUETZ, a town of Saxony, in the circle of Leipic; two miles S.S.E. of Zorbig.

QUEVACAMPS, a town of France, in the de-
partment of Jemappé, and chief place of a canton, in the dis-
trict of Tournay. The place contains 953, and the canton 10,264 inhabitants, on a territory of 1073/4 kilo-
metres, in 15 communes.

QUEVAUILLERS, a town of France, in the de-
partment of the Somme; eight miles S.W. of Amiens.

QUEUE, in Commerce, a wine measure used in some parts of France. A queue of Champagne contains 384
pintes of Paris, or about 95 English gallons; a queue of Burgundy contains 432 pintes of Paris, or 107 English gal-
lons.

QUEUE, French tail, as applied to the heads of musical notes; the minum is the only white note with a tail to it, and the
crotchet the first black note with a tail to it.

QUEUE, in Heraldry, the tail of a beak.

If a lion has a forked tail, he is blazoned by double-
queue.

QUEUE d'Aronde, q.d. swallow's tail, in Fortification, a
term applied to outworks, when narrower at the gorge than at the face or front; i.e. when the sides open towards the
champaign, and contract towards the gorge. The name is occi-
nected by its resemblance, in figure, to a swallow's tail, which the French call queue d'aronde.

Of this kind are some fingle as well as double tenailles; and some horn-work's where the sides are not parallel.

On the contrary, when the sides are less than the gorge, the work is called contre queue d'aronde.

QUEUE d'Aronde, in Carpentry, a method of jointing,
called also cleve-tail.

QUEVEDO, de Villanueva, Francisco, in Biography, a
celebrated Spanish writer, was born at Madrid in 1570.

He became distinguished at an early period for his literary
attainments, and obtained the honour of knighthood, but
indulging his fatrical vein too freely against the administra-
tion of Count d'Olivares, he was thrown into prison, from
whence he did not make his escape till the diligence of that
minister. He died in the year 1645, at the age of 75. He
is regarded by his countrymen as having attained to a con-
siderable degree of excellence in most of the different kinds of
composition. His heroic poems are said to be characterized
by energy and spirit; his lyric by sweetness and beauty;
and his humorous poems by ease, pleasantry, and ingenious
invention. His printed works fill three vols. 40 of which
two are occupied by poetry and one by prose. The former
were collected by Josepf Gonzales de Salas, who illustrated
them with notes and dissertations. They were published in
1650, at Madrid, under the title of “El Parnaso Espagnol.”
The humorous pieces of Quevedo have rendered his name
broadly known in foreign countries, and have been translated
into the English and other languages.

QUEVILLY, in Geography, a town of France, in

the department of the Lower Seine; three miles W. of

ROUEN.

QUEULEN, a river of Chili, which runs into the Pacific
ocean, S. lat. 39° 10'.

QUEYPO, a town of Mexico, in the province of Costa
Rica, near the Pacific ocean.

QUEYRAS, a town of France, in the department of the
Higher Alps; 12 miles S.E. of Briancon.

QUEYTOR, a name sometimes given to the river Ava,
at least to that part which runs between Ava and Prom.

QUI, in Rural Economy, a common term frequently ap-
plied to the female of the cow kind of animals while in the
young state. It is the most generally employed in the northern
parts of the country. See Why.

QUI-CALF, a name usually made use of in the northern
parts of the island, to signify a female or heifer calf. See
Why-Calf.

QUI TAM, in Law, is used where an information is exhi-
bited against any person on a penal statute at the suit of the
king and the party who is informer, when one part of the
penalty for breach of the statute is to be given to the
king, the poor, or to some public use, and the other part to the
informers or prosecutor; and the party informing profes-
ses for the king and himself. The suit is called a qui tam
action, because it is brought by a person, "qui tam pro domino rege,
& c. quam pro se ipso in hac parte sequitur." If the king,
therefore, himself commences this suit, he shall have the
whole forfeiture. (2 Hawk. P.C. 268.) But if any one hath a
"qui tam" or "popular" action, no other perfon can pursue it; and the verdict passed upon the defendant in
the first suit is a bar to all others, and conclusive even to the
king himself. This has frequently occasioned offenders
to procure their own friends to begin a suit, in order to
foreclose and prevent other actions; which practice is in
some measure prevented by a statute made in the reign of a
prince very sharp-minded with regard to penal laws, 4 Hen.
V. c. 26; which enacts, that no recovery, otherwise than
by verdict, obtained by collusion in an action popular,
shall be a bar to any other action prosecuted bona fide. A
prosecution, says judge Blackstone, that lears borrowed from
the rule of the Roman law, that if a person was acquitted
of any accusation, merely by the prevalence of the accuser,
a new prosecution might be commenced against him. F. 47:
153. See Information.

QUIA, in Logic, See Reason.

QUIA DOMUS REMVLT CURVAM, in Law. See Recto.

QUIA TEMPERANTE, a denomination given to the statute of
Wellm. 3. 18 Edw. I, which directs, that upon all false or
feoffments of land, the feoffee shall hold the fame, not of
his immediate feoffor, but of the chief lord of the fee, of
whom such feoffor himself held it; and hence it is held that
all manors existing at this day must have existed by immem-
orial prescription, or at least ever since this statute was made:
for no new manor can have been created since that statute;
because it is essential to a manor, that there be tenants who
hold of the lord, and that statute enacts, that for the
future no subject shall create any new tenants to hold of
himself.

QUI IMPROVIDIL, a superfeoffed granted in many cafes where
a writ is erroneously sued out, or mislaid.

Such is that granted in behalf of a clerk of the chancery
sued against the privilege of the court, in the common pleas,
and pursued to the exigent.

QUIADKOUA, in Geography, a town of Prussia, in
the province of Bartenland; nine miles S.E. of Allerburg.

QUIBBLETOWN, a town, or rather a village of Ame-
rica,
QUIBERON, a fortified town of France, in the department of Morbihan, and chief place of a canton, in the district of L'Orient, situated at the extremity of a peninsula, to which it gives name, opposite to the isle of Belle Isle; remarkable for an unfortunate expedition of English troops and emigrants against France, in the year 1795; 17 miles S.E. of Port Louis. The place contains 1,161, and the canton 5618 inhabitants, on a territory of 95 square miles, in three communes. N. lat. 47° 30'. W. long. 3° 2'.

QUIBO, a small island on the outer part of the bay of Panama; it is uninhabited, but affords wood and water for shipping.

QUIBONDO, a small island in the Indian sea, near the coast of Africa. S. lat. 8° 8'.

QUIBOR, a town of South America, in the government of Caraccas; 15 miles S.W. of Segovia Nova.

QUIBURY, a town of New Navarre; 20 miles S.S.E. of Càfà Grande.

QUICAPOUX, a river of America, which runs into the Mississippi, N. lat. 43° 2'. W. long. 92° 5'.

QUICARO, a town of New Navarre; 150 miles S.S.E. of Càfà Grande.—Also, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 7° 54'. W. long. 80° 42'.

QUICI, in Entomology, a species of the cerambyx, mentioned by Marcgrave.

QUICK, in Gardening, a term applied to signify any fort of young plant, but especially those of the white-thorn kind. By it is also often understood a live hedge, but more properly the shrubs of which such live hedges are formed. In a strict sense it is, however, applied to the crataegus oxyacantha, or hawthorn, the young plants or sets of which are commonly fold by the nurseries under the name of quicks.

In the choice of these sets, those which are raised in the nursery are in general to be preferred to such as are raised out of the woods, as the latter have seldom good roots; many persons, however, prefer them, as they are larger plants than are commonly to be had in the nurseries. See CRATAEGUS.

QUICK. See Medlar and Pyrus.

QUICK-Beam. See Pyrus, and Service-Tree.

QUICK-Beam, in Planting, a name given in some places to the tree usually known by the title of mountain-ash. It has been recommended as useful for forming fences, in some cafes, by Dr. Anderfon, and others. Where it is employed in this way, the plants must be kept down to the proper height, by being cut over as often as they may be occasioned; and thus encouraging them to throw out lateral branches in a greater abundance, and, of course, induce the fence to become more close and thick in its lower parts. By these means a tolerably perfect hedge may be raised, from plants of this fort, in situations where the white-thorn will not succeed in any proper manner.

QUICK-Hatch, in Zoology. See Unsex Lucus.

QUICK-Hedge, in Agriculture, a name given to all such as are raised from quicks, or any other fort of living plants. The proper forming and planting of quick-hedges have hitherto been much too little attended to by the farmer, as it is a matter of great importance, and which interests him in a very high degree. Whatever fort of plants may be employed for this purpose, the work should constantly be well performed in the first instance, and the hedges and plants be afterwards kept in due order and regularity by suitable pruning, cutting in, and other proper management. There is a great number of different methods of raising and making hedges of this kind, as by planting the sets on the plain turf, or the mould a little raised above it, or on mound, formed by the sods and mould dug up in the line of the hedge, elevated to different considerable heights; by setting the plants out in one row only, in double rows, or sometimes in a still greater number; by putting them in, in straight lines, in irregular manners, in the triangular form, or in the quincunx method. They are sometimes cut over at certain heights, at others not cut down at all; the fides are allowed in some cafes clipped or cut in, but in others this is avoided altogether. When planted on banks, they are mostly cleaned and moulded up annually.

A great variety of different sorts of plants is employed in forming and constructing these hedges, as those of the hawthorn, the black-thorn, the crab-tree, the hazel, the willow, the beech, the elder, the poplar, the alder, and several other kinds, according to particular circumstances and situations. And on the exposed coasts or shores of the southern parts of the kingdom, a new fort of shrub or plant has lately been recommended for this use, which is that of the tamarisk, or tamarix gallica, as it thrives rapidly, it is said, when planted in situations most exposed to the blast or broke of the sea; forms an admirable shelter, and being of quick growth, soon comes to answer the end designed. The writer of the agricultural report of the county of Cornwall has known a hedge of it, which he has been told was planted about seven years ago, and the bushes, apparently, cannot be less now than from ten to twelve feet in height, and are feathered to the very bottom. It thrives well about the Lizard, bears cutting perfectly well, and in exposed situations, where it might be injured if left to grow high, may be kept close and low to much advantage. It unfortunately, however, will not stand the frost, and should never be attempted, of course, in situations exposed to the severest effects of it. The propagation of it is by cuttings, which take root without any difficulty. It is suppos'd that this shrub was brought by the monks from Normandy to Mont St. Michael in the above county, and thence spread to other parts. See Hedge, and Quickset Hedge.

The quick-hedges of this country are in a very great degree raised from the white-thorn, which unquestionably forms the cheapest and most durable kind, where the nature of the soil, situation, and other circumstances are favourable for the purpose. It will not, however, flourish in bad land, in exposed situations, where the bottom is wet and springy, or where the growth of weeds is very abundant. In all such cafes other kinds of plants are therefore had recourse to in the formation of them.

In many upland districts beech-hedges have been planted to considerab]le extents, and found, when kept under proper management, to be very handsome, and of great service in such exposures. Birch-hedges have likewise been tried in different cafes, and found to grow remarkably fast, even in cold bare taily soils, but they require to be cut over at the time they are about four feet in height and carefully plased. Both these sorts of hedges have this in their favour, that they will grow in very poor soil as well as in very exposed situations; and both will flourish and grow strongly where the white thorn cannot live. Their want of prickles, however, is a great objection to them in this view; but they afford good shelter.

Quick-hedges constitute the ordinary fort of fences in this country, and unless in particular situations, and for particular purposes, are the most proper and eligible. It has been
been observed by the writer of a late work, that in parts which have been long inclosed without arable cultivation, hedges, of seemingly great age, are met with, which are many times crooked, ragged, and irregular, as though they had been, in the first instance, formed and laid out from the wild underwood of such places. While in other cafes, low plants of the various coppice kinds rise and grow on dikes or mounds but little raised above the surface of the land, seemingly as though they had formerly been collected from brush-woods and replanted on such banks, in some few of the same manner as is still practised on higher banks in particular districts towards the west, and in South Wales. But taking the country at large, the method of raising quick-hedges by setting grown plants taken from such situations, has long ceased to exist and prevail as a general practice; young plants of white-thorn, or other sorts, set out in the bank and ditch mode with a low protecting dead fence on the side: contrary to the ditch at first, is the plan commonly had recourse to, such plants being first raised in small grounds for the purpose in regular rows, and not taken, as formerly, from brush-woods and waffle commons.

Quick-Lime, in Rural Economy, such lime as is in the caulific or most active state, and which possesses the greatest power of operating upon different substances with which it may come in contact. It is quite the opposite in its qualities and properties, so that which has fallen down into a powdery state, in consequence of being faterated with water and carbonic acid gas, or fixed air, or which is cracked and become effete. Its powers, when applied upon land in this condition, have already been noticed in speaking of lime. See Lime.

But it possesses qualities and properties in the way of a cement, the utility of which for building, for various domestic purposes, properly belong to this place. According to Dr. Anderson, lime is in the belt and most fit state for this use when the most perfectly caulific, or in the most crystallizing condition. It is remarked, that the powder of lime, when reduced by means of water into a thin or fluid part of paste-like form, and then suffered to become dry, concretes into a coherent mass, which fixes to itones and other hardbodies in a very firm manner, and in this way becomes a proper cement for building any sort of walls. And that, after this pasty material has once become firmly dry, it is quite indissoluble in water, and incapable of ever being softened again by the moisture of the atmosphere or other similar causes. Hence it exceeds many other sorts of cements. When composed for the purpose of building walls, &c. it is usually denominated mortar; but when formed as an application in the way of a smooth coating upon any plain surface without intermixture with flony matters, it is commonly here termed playfer.

When made from the lime of the purer sort of lime-stone, it is found to be more soft and crumbly, and to acquire a lefs degree of hardnes, and to be broken with much lefs force, than where the lime-stone from which it is made contains a large proportion of sand, in which case it becomes much more hard, firm, and durable.

It has, however, been discovered that the purest lime may be rendered a firm cement by adding a proper proportion of clean hard sand to it; hence the practice of blending sand with lime, when intended for mortar, has become so universal. This is fully flown to have been very early the case, by the oldest lime-built walls which are now to be met with.

It nevertheless still remains a desideratum to ascertain the due proportion of sand which is necessary, as both writers and practical masons greatly disagree in opinion on this matter, as well in their directions about the mode of mixing the materials, as of applying the cement; some of the more modern, especially, ascribing extraordinary effects to a small variation in these particulars, while others deny that these circumstances have any sensible effect on the durability and firmness of the cement.

It is conceived that these different and contradictory opinions arise from an imperfect knowledge of the nature of quick-lime, and the variations it may admit of; for these variations are so great, as to render it impossible to afford any general rules that can possibly apply in all cases. It is, therefore, conceived to believe those who are desirous of acquiring any confident and satisfactory knowledge on this head, to endeavor to ascertain, in the first place, the circumstances which render calcareous substances at all capable of becoming a cement, and then to trace the several changes that may be produced upon it by other extraneous causes. Having explained the circumstances which cause the differences in lime-stone, and pointed out the different constituent principles of it, as well as various other peculiarities; it is stated that lime, which has in any way absorbed its full quantity of air from the atmosphere and become mild, is altogether unfit for becoming a cement, and that, of course, it is evident, that a great change may be produced upon the quality of any lime, by having allowed lefs or more of it to be in this state before it is worked up into mortar. And further, that if a large quantity of water be put to fresh flaked quick-lime, and beat up with it into a thin sort of pate, the water diffolves a small portion of the lime, which as it gradually absorbs its air, is converted into crystals; between the particles of which crystals, that part of the lime which was not diffolved, and the other extraneous matters which may have been mixed with it, are entangled, so as to form a firm coherent mass of the whole. And that the pesty substance formed in this manner, is the well-known article mortar; and this heterogeneous, imperfectly semi-crystallized mass, constitutes the common cement employed in building ordinary walls or other erections. These circumstances, therefore, being known, it is thought that it will not be difficult to comprehend what are the particulars that are necessary to form the most perfect cement of this nature. That since lime becomes a cement only in consequence of a certain degree of crystallization taking place in the whole mass, it is sufficiently obvious that the firmness and perfection of that cement must depend upon the perfection of the crystals; and the hardness of the matters that are entangled among them; for if the crystals are ever so perfect and hard of themselves, if they be separated from one another by any brittle incoherent medium, it is evident that the whole mass must remain in some degree brittle and incoherent. That as water can only dissolve a very small proportion of lime, even when in its most perfect saline or caulific state, or while it remains deprived of its carbonic acid gas, and as happens in other similar cases, no more of the lime can be reduced to a crystalline mass than has been actually diffolved in the water; it happens of course, that if mortar be made of pure lime and water alone, a very small proportion only can be dissolved by that small quantity of water that is added to it: and as this small proportion alone can afterwards be crystallized, all the remaining undiffolved particles of the lime will be entangled among the few crystals that are formed. And as the undiffolved lime in this mass will in time absorb its air, and be converted into mild calcareous earth without having had a sufficiency of water to allow it to crystallize, it must concretely into a friable mass exactly resembling chalk; it follows, that this kind of mor-
QUICK-LIME.

mar, when as dry as it can be made, and in its highest degree of perfection, will always be soft, and easily crumbled into powder.

But that, if, instead of forming the mortar of pure lime alone, a large proportion of sand be added to it, the water will in this case dissolve as much of the lime as in the former; and the particles of hard sand, like sticks or threads, when making sugar-candy or other crystals, while surrounded by the watery solution, will help to forward the crystallization, and render it more perfect than it otherwise would have been, so as firmly to cement the particles of sand to one another. And as the gransules of sand are perfectly hard of themselves, so as not to admit of being broken down like the particles of chalk, it necessarily follows, that the cement made of these materials must be much more perfect in every respect than the former.

After considering a variety of circumstances in regard to the solubility of lime in water, and its crystallization, it is remarked, that when a large quantity of sand is mixed in the mortar, that sand will of course bear a great proportion to the whole mass; so that the water that may be mixed with the sand must be much greater in proportion to the quantity of lime contained in this mortar, than if the whole had consisted of pure calcareous matter. And that, as the sand absorbs none of that water,—that water, now pure, is at liberty to act on more upon those few particles of caustic lime that may still remain in the mortar, which will be dissolved and converted into crystals in their turn. In this way it may happen, in some circumstances, that a very large proportion of the lime may become crystallized; so that the mortar will consist almost entirely of sand enveloped in crystalline matter, and become in due time as hard as stone itself; whereas mortar, consisting of pure lime, without sand, can hardly ever be much harder than chalk. It is not, however, to be supposed, that in any case this dried mortar will assume that transparent crystalline form, or the compact firmness of some sorts of calcareous matters, such as marble and lime-stone. In mortar, in spite of the utmost care that can ever be taken, a very considerable quantity of the lime must remain undissolved; which undissolved lime, although it may be so much separated by the sand and crystalline lime-stone as not much to affect the hardness of the mortar, yet it must still retain its white chalk-like appearance. As marble and lime-stone are, however, always formed by those particles of lime that have been wholly dissolved in water, and from which they have been gradually separated by a more fluid and more perfect mode of crystallization, they have nothing of that opaque calc-like appearance, but assume other colours, and appear more firm, uniform, and compact; the sand and other matters that may be enveloped in them being entirely surrounded with a pure crystalline matter.

But to obtain the most perfect kind of mortar, it is not, however, enough that a large proportion of sand should be employed, and that the sand should be intimately mixed with the lime; it is also of the utmost importance that a large proportion of water be added; for without this it is impossible that a large proportion of the lime can be crystallized; and the mortar, in that case, would consist only of a mixture of chalky matter and sand, which could hardly be made to unite at all, and would be little more coherent than sand by itself, and less so than pure chalk. In that case, pure lime alone must afford rather a firmer cement than lime with sand. It is also of very great importance that the water be retained as long in the mortar as possible; for if it be suddenly evaporated, it will not only be prevented from acting a second time upon the lime, after a part of what was first dissolved has been crystallized, but even the few crystals that would be formed when the water was suddenly evaporating, would be of themselves much more imperfect than they otherwise most certainly would have been. In proof of which, infallencies of the crystallization of common salt, lump sugar, and sugar-candy, are adduced; after which it is noticed, that every one knows what a difference there is between the firmness of the different sublimations; and that as great must be the difference between the firmness of that cement which has been slowly dried, and that which has been hastily hardened by the powerful action of a warm air.

It is contended, it is owing to this circumstance that the lime, which remains all winter in a mortar tub filled with water, is always found to be much firmer and more coherent than the mortar that was taken from the same tub and used in any work of masonry, although in this case the materials were exactly the same. From the same cause, any work cemented with lime under water, if it has been allowed to remain undisturbed and uninjured until it has once become hard, is always much firmer than that which is above the surface of the water.

In order to render the force of the above reasoning more strong and convincing, lime cement or mortar is compared to a mass of matter consisting of a congeries of stones closely compacted together, and united by a strong cementing matter that had, while in a fluid state, pervaded all the interstices between the stones, and afterwards become a solid indissoluble substance. If the cementing matter be exceedingly hard and coherent, and if the stones bedded among it be also very hard and firm, the whole mass will become like a solid rock, without fissures, that can hardly be broken to pieces by the power of man. But, although the cement should be equally firm, if the stone, of which it consists, be of a soft and friable nature, suppose chalk or sand-stone, the whole mass will never be capable of attaining such a degree of firmness as in the former case; for when any force is applied to break it in pieces, although the cement should keep its hold, the solid matter cemented by it would give way, and the whole would be easily broken to pieces. Whereas in mortar, the sand that is added to it represents the stones of a solid matter in the composition, the particles of which are united together by the lime which had been formerly dissolved, and now crystallized, which becomes an exceedingly solid and indissoluble concretion. And as the particles of sand are of themselves exceedingly hard, and the cement by which they are united equally so, it is plain that the whole concretion must be extremely firm, so as to require very great force to disunite any particle of it from the whole mass. But if, instead of employing sand, the only solid body that is entangled among the cementing matter should be chalk, (as in all cases where the mortar consists of pure lime alone,) or any other slightly cohering substance, the cementing particles of that composition being so perfect, it is impossible that the whole can ever attain a great degree of firmness, as these chalky matters will be easily broken asunder.

It is remarked, in addition, that a variety of conjectures have been made about the nature of the lime cement employed by the ancients. It has been thought that they possessed an art of making mortar, which has been long since entirely lost; as the cement in the walls which have been built by them, appears to be, in many cases, much firmer than that which had been made in modern times. Yet, when the mortar of these old buildings is analyzed, it is found to consist of the same materials, and nearly in the same proportions, in which they are now made use of.
QUICK-LIME.

And it is thought probable, that their only secret consisted in mixing the materials more perfectly than the rapidity or avarice of modern builders will permit, in employing their mortar in a much more fluid state than is done now, and in allowing it to dry more slowly, which the immoderate thickness of many of their walls would naturally produce, without any preconcerted design on their part. Tradition has even handed down to the present times the memory of the most esoteric of these particulars; as the lower classes of people, in every part of the nation, at this moment invariably suppose and believe that these old walls were composed of a mortar so very thin, as to admit of its being poured, like a liquid, between the stones, after they were laid in the course: and the appearance of these old walls, when taken down, seems to favour this popular tradition. Nor is it doubted but that this may have been the case. The stones in the outer part of the wall, it is thought, were probably bedded in mortar nearly as is practiced at present; and the heart, after being packed well with irregular stones, might have the interfaces between them entirely filled up with fluid mortar, which would infuse itself into every crevice, and in time adhere as firmly as the stones themselves, or even more so, if the stones were of a sandy friable nature. And that, as these walls were usually of very great thickness, it might often happen, that the water in this mortar, by acting successively upon different particles of caustic lime, would at length be entirely absorbed by successive crystallizations, so as to become perfectly dry, without any evaporation at all; in which case, a very large proportion of the original lime must have been regularly crystallized in a low and tolerably perfect manner, so as to attain a firmness little inferior to lime stone or marble itself.

It is supposed that, upon these principles it is easy to account for the superior hardness of some old cements, when compared with that of modern times, in which a practice very different is usually followed, without having recourse to any wonderful arcana whatever.

Monseur Loriot, a late French writer, imagined that he had made a perfect discovery of the way in which the ancients employed their quick-lime, so as to obtain such an extraordinary firm cement; from which discovery, he conceived, very important benefits might be derived to society. According to his opinion, the ancient cement consisted of lime and sand nearly in the same proportions as are commonly employed for that purpose at present. But instead of making it of flaked lime entirely, as is done now, he contends that they employed a certain proportion of their lime unfaked, which they mixed with their mortar immediately before it was used. And it is further noticed, that this newly discovered cement dries and hardens almost under the hand of the operator, without cracks or flaws of any sort; that it neither expands nor contracts with the air;—that it is impervious to moisture, and may not only be employed for making roofs of houses that are subjected to the continual dripping of water, basins, aqueducts, canals, &c., which will infallibly contain water in any quantities, but even finer works of the pottery kind; that it perfectly refits frosts, and has a variety of other interesting qualities. The trials of Dr. Anderson on the same fort of materials do not, however, confirm the great certainty and utility of this discovery. "That such effects as the writer describes," says the doctor, "will invariably be produced, merely by adding a certain proportion of unfaked lime in powder to mortar, or even by making the mortar entirely with powdered quick-lime, I may without hesitation venture to deny, not only from the reasoning that has been given, but from actual experiment, again and again repeated by myself, and which is likewise, in some measure, corroborated by the experience of Mr. Doffie."

On these accounts, it is supposed, that if Monseur Loriot, has really experienced these uncommon effects from the mortar he has tried, it must have been occasioned by some other unobserved peculiarity, and not merely by the circumstance to which he seems to ascribe it. Possibly the doctor supposes the lime he employed may have been impregnated with a gypsum, or the sulphate of lime, as is probable, for many reasons. The effects and qualities of which, as to becoming a fine powder, and of suddenly setting, are well known, but it never acquires the flaky hardness that lime cement is sometimes endowed with, although it takes the smoothest polish of any cement we know: on which account, it has long been employed as a plasters where fine ornaments are required.

There are unquestionably, however, many doubtful and mysterious circumstances connected with this matter, which require the aid of further trials and experience in their full explanation.

There are still further a few other circumstances that may influence the quality of common lime-mortar. If lime-tone be sufficiently calcined, it is deprived of all its moisture, and of all its carbonic acid gas, or fixed air. But experience shews, that lime-tone will fall to powder on the effusion of water upon it, when it is much less perfectly calcined, and while it still retains almost the whole of its fixed air. And that as masons have hardly any other rule for judging whether lime-tone be sufficiently calcined, except this single circumstance of its falling to a powder when water is poured upon it, it may thus easily be perceived, that the same lime may be more or less fitted for making good mortar, according to a circumstance that, in a great measure, eludes the observation of operative masons; for if it should happen that all the pieces of lime drawn from a kiln at one time, were just sufficiently calcined to make it fall to a powder with water and no more, that powder would be altogether unfit for making mortar of any kind. This is a case that can seldom happen; but as there are a great many intermediate degrees between that state and perfect calcination, it must often happen that the lime will approach nearer to one of these extremes at one time than at another; so that the mortar may be much more perfect at one time than at another, owing to a variation in this particular.

All those who have written on the subject of lime as a cement, have endeavoured to ascertein what is the due proportion of sand for making the most perfect cement. But a little attention to the matter will shew, that all rules, which could be preferred as to this particular, must be too vague and uncertain, as to be of little utility to the practical mason; as, besides the variation which may arise from a more or less perfect degree of calcination as above, it is a certain fact, that some kinds of lime-tones are much more pure, and contain a much smaller proportion of sand than others do; some being found almost perfectly pure, while others contain eleven-twelfths of sand and all the intermediate proportions of it. Therefore it would be absurd to lay that pure lime would require as small a proportion of sand when made into mortar, as that which originally contained in itself a much larger proportion of sand than any writer has ever ventured to propose for being put into mortar.

Besides, there are differences caused by the different nature of the calcination in the different sorts of lime-tone, from which it may, upon the whole, be concluded, that
about one-tenth of pure lime-flour is not enough calcined to admit of being made into mortar; and that of the most impure forts of lime-flour, not above one-fourth of the lime contained in it is so much calcined as to be in a caustic state.

The variation that is produced by these means in regard to the proportion of sand that will be required to the lime in the one or the other case, is found to be so extremely great as hardly to be conceived. It is, however, stated, that the beat mortar that has been seen made, was formed of lime which had been found to contain eleven parts of sand to one of lime: to this there was added between twice and thrice its whole bulk of sand by measure; which may be allowed to have been at least three times its quantity by weight. Therefore, supposing that every particle of that lime had been so perfectly calcined as to be in a caustic state, there could not be less than forty-four parts of sand to one of lime. As much may, however, be allowed for the uncaustic part of the lime as is pleased, and the calculation made accordingly. But it is hardly possible to suppose that above one-hundredth part of this mass, independent of the water, consisted of pure caustic calcareous earth.

On these considerations it is conceived, that it is impossible to prescribe any determinate proportion of sand to lime, as that must vary according to the nature of the lime and other accidental circumstances, which would form an infinity of exceptions to any general rule. But it would seem that it might be safely inferred that the moderns in general rather err in giving too little sand, than in giving too much. It deferves, however, to be noticed, that the sand, when naturally mixed with the lime than can possibly be ever affected by any mechanical operation; so that it would be in vain to hope to make good mortar artificially from pure lime, with such a small proportion of caustic calcareous matter as may sometimes be affected when the lime naturally contains a very large proportion of sand. But there seems to be no doubt, that if a much larger proportion of sand were employed, and if that were more carefully blended and expediently worked, than is common, the mortar would be much more perfect than is usual in modern times, as has been proved by actual trials.

Another circumstance that tends greatly to vary the quality of cement, and to make a greater or smaller proportion of sand necessary, is the mode of preparing lime before it is beaten up into mortar. When for platter, it is of great importance to have every particle of the lime-flour flaked before it is worked up; for, as smoothness of the surface is the most material point, if any particles of lime should be beaten up in it, and employed in work before sufficiently fallen, the water, still continuing to act on them after it was worked up, would infallibly flake such particles, which forcibly expanding themselves, would produce those excrescences on the surface of the platter commonly termed blisters. Consequently, in order to obtain a perfect kind of platter that will remain smooth on the surface and free of blisters, there is an absolute necessity to allow the lime to lie for a considerable time macerating or fouling in water, before it is worked up. And the same fort of process is necessary for the lime when intended for use as mortar, though not so absolutely. Great care is, however, required in the management in this respect; the principal things being the getting of well-burnt lime, and the allowing it to macerate or foun on the water for only a very short time before it is used; but that which is the beat burnt will require the maceration of four days in the water before it is sufficiently flaked in the whole mass for this purpose. See Sourino Lime for Mortar and Platter.

It has been almost universally admitted, that the hardest lime-flour affords a lime that will consolidate into the firmest cement; and hence generally concluded, that lime made of chalk, produces a much weaker cement than what is made of marble or lime-flour. It would seem, however, that if ever this be the case, it is only incidentally, and not necessarily so. As from the nature of calcareous matter, every kind of lime is equally fit for becoming a firm cement, if it be first reduced to a proper degree of causticity, and has afterwards a due proportion of sand properly mixed with it, before it be employed in work. Different forts of lime, without doubt, differ much from each other in the proportion of sand they naturally contain, and, of course, require very different proportions of sand to be added to them before they can be made equally perfect as a cement; which is an economical consideration, of no small moment in some cases, as it may make one fort of lime a great deal cheaper than another on some occasions, and, of course, deferves the attention of builders in general. See Lime.

The excellencies and defects of other substancess that may be occasionally mixed with lime in making cement may be just noticed. Those commonly used as an addition to mortar, besides sand of various denominations, are powdered sand-flour, brick-dust, and sea-shells. And for forming platter, where choianes rather than hardnes is required, they are lime that has been flaked and kept long in a dry place, till it has become nearly effete, powdered chalk or whiting, and gypsum in various proportions; besides hair and other materials of that nature. But some others have been more lately advised, such as earthy bolls, flintly burnt and pounded, powdered and fitted old mortar rubbish, and others of a similar kind. All of which substancess are found objectionable in some respect or other for this use, and being the only perfectly mutable material that can be easily met with; on which account it has been always justly preferred. Pure firm crystallized sand is the best, but all pure sands are not equally proper in this intention, see these substancess respectively. See also Cement and Sand.

It is stated by Sir Humphry Davy, in his work on "Agricultural Chemistry," that there are two modes in which lime acts as a cement; in its combination with water, and in its combination with carbonic acid. When quick-lime is rapidly made into a paste with water, it foons loses its softness, and the water and the lime form together a solid coherent mass, which consists of seventeen parts of water, to fifty-five parts of lime. When this hydrate of lime, while it is consolidating, is mixed with red oxdy of iron, alumina, or silica, the mixture becomes harder and more coherent than when lime alone is used; and it appears that this is owing to a certain degree of chemical attraction between hydrate of lime and these bodies; and they render it less liable to decompose by the action of the carbonic acid in the air, and less soluble in water. It is thought that the basis of all cements that are used for works which are to be covered with water must be formed from hydrate of lime; and that the lime made from impure lime-flours answers this purpose very well. Puzzolana, it is said, is composed principally of silica, alumina, and oxdy of iron; and it is used mixed with lime, to form cements intended to be employed under water. It is stated that Mr. Smeton, in the construction of the Eddyflone lighthouse, used a cement composed of equal parts, by weight, of flaked lime and puzzolana. Puzzolana, it is said, is a decomposed lava, or ashes, which was formerly imported in considerable quantities from Holland, is found to
to be a mere decomposed basalt: two parts of flaked lime and one part of tarsa form the principal part of the mortar used in the great dykes of Holland. It is supposed that substances which will answer all the ends of puzzolana and tarsa, are abundant in the British isles. An excellent red tarsa may be procured in any quantities from the Giant’s Causeway, in the north of Ireland: and decomposing basalt is abundant in many parts of Scotland, and in the northern districts of England in which coal is found.

It is observed that Parker’s cement, and cements of the same kind made at the alum-works of lords Duncais and Mulgrave, are mixtures of calcined, ferruginous, sileceous and aluminous matter, with hydrate of lime.

It is noticed, that the cements which act by combining with carbonic acid, or the common mortars, are made by mixing together flaked lime and sand. These mortars at first solidity as hydrates, and are slowly converted into carbonate of lime by the action of the carbonic acid of the air. It was found by Mr. Tennant, that a mortar of this kind, in three years and a quarter, had regained fifty-three per cent. of the quantity of carbonate of lime, which constitutes the definite proportion in carbonate of lime. The hardnes of the mortar in very old buildings is also thought to depend upon the perfect conversion of all its parts into carbonate of lime. The purer lime-flakes are the best adapted, it is said, for making this kind of mortar. The magnefian lime-flakes make excellent water cements, but act with too little energy upon carbonic acid gas to make good common mortar. The Romans, on Pliny’s authority, made their mortar a year before it was used; so that it was partially combined with carbonate of lime gas before it was employed, it is supposed.

It is likewise suggested, in regard to the cultivation and improvement of land by means of this material, that quick-lime in its pure state, whether in powder, or diffused in water, is injurious to plants; grass in several instances having been killed by watering it with lime-water; but that lime, in its state of combination with carbonic acid, is an useful ingredient in soils. Calcareous earth is found in the ashes of the greater number of plants, and exposed to the air, lime cannot long continue calcic, but soon becomes united to carbonic acid. That lime, when combined with about one-third of its weight of water, constitutes hydrate of lime; and that it becomes carbonate of lime by long exposure to the atmosphere, the place of the water being supplied by carbonic acid gas. On mixing freshly burnt or flaked lime with any moist fibrous vegetable matter, a strong action occurs between them, and they form a sort of compost, part of which is commonly soluble in water. In this way, lime renders matter, before comparatively inert, nourishing; and from charcoal and oxygen, abounding in vegetable matter, it becomes converted into carbonate of lime at the same time. Mild lime, or powdered calcareous substances, have no action in this way on vegetable matter; by their operation they prevent the too quick decomposition of bodies previously diffused; but do not tend to form soluble matters. Consequently it is clear that the operation of quick-lime and mild calcareous substances, depend upon wholly different principles. The former, on being applied to land, tends to bring the hard vegetable matter contained in it into more rapid decomposition and solution, as a proper food for plants. The latter only improve the texture of it, or its relation to aborption: it is merely an earthy ingredient. Quick-lime, in becoming mild, has a similar action, but while taking on that state, prepares soluble out of insoluble matter. On this depends the operation of lime in the preparation for wheat crops, its efficacy in fertilizing peat, and in bringing into cultivation all sorts abounding in hard roots, dry fibres, or inert vegetable matter. The question, of course, whether quick-lime should be applied to land or not, depends on the quantity of inert vegetable matter it contains; and that whether mild lime, marle, or powdered lime-flake, should be used or not, on the quantity of calcareous matter already in the land. All sorts of land are improved by mild lime, and ultimately by quick-lime, which do not effervesc with acids; and the sandy sorts more than the clays kinds. In land deficient in calcareous matter, but containing much soluble vegetable manures, the use of quick-lime should definitely be avoided, as tending either to decompose the soluble matters, by uniting to their carbon and oxygen in becoming mild, or to combine with the soluble matters, and form compounds with less attraction for water than the pure vegetable substance. The fame is the case in regard to most animal manures; but its operation is different in different cases, according to the nature of the animal matter. On the whole, it should however never be employed with animal manures, except when too rich, or for preventing noxious effluvia. It is hurtful in mixture with common dung, and tends to produce infusibility in the extractive matter. It is useful in mixture with simple vegetable barks, etc.

The solution of the question about the inutility and disadvantage of magnesian lime, which has lately been found useful in small quantities on the poorer lands in Leicestershire, as from twenty-five to thirty bushels the acre, and in larger ones, on the rich soils; it is supposed to depend upon that fort of lime having a less attraction for carbonic acid than the other, in consequence of the portion of that substance in it, and thereby remaining longer in the calcic flake; and its becoming sooner a carbonate of lime in the rich than in the poor soils. Magnesia, while in the calcic flake, is poisonous to certain kinds of plants, and acts in the mixture as lime. It may be usefully applied in large quantities to peat-earths; and to lands injured by too much of this fort of lime, peat-earth will be a proper and effectual remedy, when used in a suitable proportion.

More full information may be met with on this curious and interesting subject in the first volume of Anderson’s Essays on Agriculture and Rural Affairs, in Dufic’s Memoirs of Agriculture, vol. ii. and in Sir Humphry Davy’s “Agricultural Chemistry.”

Quick-Manures, a term sometimes applied to that fort which is spread over crops upon the surface of the land, such as foot, small dung, different sorts of ashes, &c. As manures in this intention on pasture lands, wheat, clover, tare, and other similar crops, twenty bushels of foot is recommended to the acre, sixty bushels of rabbit or poultry dung, and sixty of pigeons’ dung and ashes; but much larger as well as smaller proportions are made use of in different inferences and circumstances. The foot and dung should be thrown over the crops about the middle of March, the ashes in February, and all in the most equal and exact manner possible, as much depends upon this being properly performed. See Ashes, Dung, and Soot.

In different counties there is much difference in the use of substances of these kinds in this way as manures. In Hertfordshire the usual quantities of foot employed in this manner are from about twenty to forty bushels, on the wheat crops; but in some places they are used to the extent of fifty or more on the acre. The application of this material is universal throughout almost every parish in the whole county, in this mode and intention. Ashes in the same district are considered by some as rendering the soil more light and open, without contributing, in any great degree,
to the nutrition of the crops over which they are sown. The proportions in which they are used to the acre over the clover, and occasionally the wheat crops, are from fifty to one hundred bushels. They are supposed to be very serviceable to the two clover crops, and greatly beneficial to the succedaneum wheat one, by some persons; but others are of quite the contrary opinion, thinking them of very little use to the wheat, except by increasing the quantity of the clover. They are also useful in destroying mos in the surface of is the fine of lands. They are to be kept dry, and commonly sown over the crops in November or January in mild moist weather.

In Oxfordshire, peat-slakes are made use of from about twelve to forty bushels upon the acre; and those of coal from sixteen to upwards of fifty. They are sown over the wheat, clover, safflower, and turnup crops, the coal being somewhat the best on the clovers, and the peat on the turnips.

In Berkshire, peat-slakes are used very generally for most sorts of crops, except wheat, barley, and peas, either sown with the furrows, harrowed in together, or thrown on the land as a top-dressing, only; but they are more preferred for all sorts of artificial grass crops, and on natural meadow and pasture grasses, as well as turnips. The quantities employed are from fifteen to twenty bushels and upwards on the acre. They are applied in March or April, several acres being capable of being sown in the course of the day. They only last about a couple of years in the land. The ashes of bean chaff are likewise found beneficial hereabouts, bringing up white clover when put upon the grass lands.

Different sorts of ashes have been found very useful on the grass lands in Suffex, at the rate of from twenty to thirty bushels on the acre, employed as a manure.

In Essex coal-slakes are laid upon the clover, safflower, and grass crops to the quantity of sixty bushels on the acre or more, with very great effects in promoting their increase.

In the county of Hertford they manure for turnips and some other crops with rabbit and poultry dung, at the rates of from fifty to sixty bushels or more on the acre, with good success. And in some part of the Oxford district, pigeons' dung is found an excellent manure when thrown over the young barley crops, mixed with that of poultry. In Essex too, it is found beneficial for promoting seed when sown over the rape or cole crops in the proportion of eight bushels to the acre.

There are several other articles which are occasionally thrown over crops on the surface of the land as a manure, in this intention, such as those of the duff of malt, rape-cake, bones, plaid of Paris, and some others. Malt-duff is made use of on wheat and barley in many parts of the county of Oxford, and on the young wheats in Hertfordshire, in the quantity of five quarters to the acre. In Berkshire thirty bushels per acre. Rape-cake duff is also used in the former of those last counties on the wheats with great success. Pounded bones are likewise greatly beneficial when strewn over the grass and some other sorts of crops, being sometimes a very forcing manure, and at the same time killing. The plaid of Paris has been used on clover, safflower, lucerne, and other crops with immense effect, in some parts of Oxfordshire, thrown over them about March, to the quantity of six bushels per acre. But in Suffolk, in the proportion of eight bushels to the acre, when sown over natural grasses, bean, potato, pea, and barley crops, it had not the least good effect. Nor even when tried on other sorts in the quantity of six bushels to the same extent of land.

Powdered oil-cake that has been spoiled by keeping, is an excellent application as manure in the above way. The same is the case with chopped tanners' hair, which has been found superior to this use to either malt-duff or any sort of calcareous matter. Horn-standings are likewise very beneficial when laid on in this manner to grass lands, in the proportion of from fifty to one hundred bushels to the acre, lasting five or six years, and being of very easy carriage they should be employed in damp weather about February or March. See Manure.

All these different sorts constitute excellent quick forcing manures, when applied in some of these ways for some of the above purposes, and should be much more generally employed in such methods than is at present the case.

**Quick Match, in Artillery, is formed of three cotton threads drawn into length, and dipped in a boiling composition of white wine vinegar, saltpetre, and mealed powder. After this immersion, it is taken out hot, and laid in a trough where some mealed powder, moistened with spirits of wine, is thoroughly incorporated into the twists of the cotton, by rolling it therein; thus prepared, they are taken out entirely and thrown through a roughened powder, and then hung upon a line to dry. There is also a quick match made of worlief instead of cotton. For its use, see Fire-Ship.**

**Quick with Child, in Law. See Reprieve.**

**Quick Pork, in Medicine. See Pulse.**

**Quick Sand, in Sea Language, denotes a looeful quaking sand, into which a ship sinks by her own weight, as soon as the water retires from her bottom. See Quicksand.**

**Quick Thorn, in Agriculture, a name frequently applied to young plants of the hawthorn or white-thorn kind, which are fit for being planted out for the purpose of forming a hedge-fence. See Quicks.**

It also signifies this fort of thorn generally.

**QUICKEN TREE, in Gardening, the common name of a tree of the ornamental fruit kind. See Sorbus.**

**QUICKENING, in Midwifery, the first perception women have of the motion of the fetus. This usually happens in the third or fourth month of pregnancy. It has puzzled physiologists to explain why the motion of the fetus should not be perceived earlier, as it is endowed with life from the first moment of conception. But, besides that the parts of the fetus are too soft and tender to affect the uterus by its motion, the membranes enveloping it are too thick, and there is then a proportionally larger quantity of fluid in the ovum than afterwards, which keeps the embryo from touching the sides of it. The uterus also during this period is confined in the cavity of the pelvis, which being of small capacity, and every way surrounded with bones, leaves little room for the motion of the fetus. But as soon as the uterus emerges into the cavity of the abdomen, it readily yields to the motion of the included fetus, and the parts by which it is now surrounded being extremely delicious and flexible, they are affected by the slightest motion---or. In some women of delicate habits, the moment of quickening is marked by a slight hysterical paroxysm. In these cases it seems probable, that the uterus has flipped suddenly into the abdomen, but ordinarily it rises slowly and gradually, whence the shock on the bowels is so incon siderable, as scarcely to make any sensible impression. See Contraction.**

**QUICKENING-Drag, in Agriculture, a name sometimes given in different districts to the couch and quick drag. See Drag.**

**QUICKJOCK, in Geography, a town of Sweden, in the Lapmark of Lutca; 15 miles N.W. of Lutca. N. lat. 69° 30'. E. long. 17°.**

**QUICKS,
QUICKS, in Agriculture, a name commonly given to the young fets of the white-thorn, which are used in planting hedges of that fort. See Quickset Hedge.

It is thought to be indispensably necessary to the success of this fort of fets, as hedge plants, in every situation, that they be well provided with roots and root fibres of the healthy kind, by Mr. Nichol, who has had much experience upon the subject. And that this is best secured by taking them from a fennary of rich mould at the end of the first or second year, according to their strength; and nursing them, after that, likewise in rich earth, for one or two feasons longer at the farthell: but, in the latter cafe, removing them into fresh rows at the end of the first year. It is contended, that plants of this age, and thus treated, will outgrow thofe of greater size in any fort of foil or situation. This has been repeatedly proved by impartial trials; and the cafe, it is fuppofed, is obviously this, that small plants, even by the fame treatment, are raised with better roots, in proportion to their items, than large ones. Therefore in the choice of quicks, regard fhould be had to the roots, not the tops of the plants. Their being nurfed the feafon previous to their being removed for hedging purpofes, in rich mellow earth, and being allowed a fufficiency of room, kept clear of weeds and other matters, is the beft mode of preparation, it is imagined, that can possibly be adopted.

There is, however, it is maintained, a double advantage in making ufe of young plants of this nature. They are cheaper and fitter for exposed situations than thofe of older growths; not becaufe their tops are lefs bulky, which, since they are to he cut over about half their lengths before being planted, is immaterial, but becaufe they have better proportioned roots to the fize and strength of the items, and of course are better fitted to feek nutriment for their common fuffenance and support.

The items of the plants, as has been fuggedted above, fhould be cut over about half their lengths, or, in general, about fix inches above the ground mark; an operation which may be performed by the common hedge hearers, a large fharp knife; or by gathering a handful of them evenly, and laying them upon a block or other familiar body, and chopping them off by means of a hatchet. They fhould always be carefully raifed, and even the fmalleft fibre be retained. And at all times, until replanted, the roots fhould be expofed as little as poftible to the air or atmosphere. See Quickset.

Quick is a term sometimes applied to the weed called couch-gras, in different places, and which is of a very troublefome nature, not being extirpated out of the land without much difficulty. See Couch.

QUICKSAND, any fort of spot or bed of running land, either near to the surface of the foil, or at any depth below it, which has a fhaking quaggy feel under the foot at certain times or feafons, in conformance of containing certain proportions of water. The writer of the work on "Landed Property" has remarked, that they are for the most part topical, and in general only temporary, commonly appearing in and after wet feafons only; clofing and becoming firm when their supplies of moisture are exhausted by long drought. In these cafes the surfaces are free from the deposition of the moory earth of bog plants, which demand a conftant coolnefs, if not a perpetual fupply of moisture, being caufed by heads or small beds of fand or gravel rifing through firmer strata to the surface. They are of course apt to be fcorched in dry hot feafons. In order to remove them, the fame writer advises, that the centre of the part which is affected fhould be marked out

when the feafon is wet, in order that a drain may be cut, when it is dry, of a fufficient depth quite up to the mark, letting it have the neceffary defects, and then filling it with fuitable materials to admit of the water being conveyed off as it is collected in the sub-foil. When the defect has been thus removed, where it is fitted in the area of a field, it is a good practice to cover the part by foil of the fame nature as that of the field where it is fitted, by bringing it from those parts which are the moft elevated, as by this means it may be rendered of an uniform quality with the reft, and of course have a better appearance, as well as be more advantageous in the growth of crops.

Dangerous tracts and spots of this nature are frequently found in marshy and fandy lands, which are occasionally covered by the tides. And large deep beds or layers of quick or running land are often met with in digging pits, quarries, mines, and other forts of shafts, to great depths under the ground, and caufe much trouble and difficulty in getting on with fuch kinds of work, on account of the quantities of water which they contain and let pafs off into them: thus occafioning the neceffity of much difficult drainage, and other inconveniences. See Quarries, Pitt, &c. Drainage of.

QUICKSAND Bay, in Geography, a bay on the weft coast of North America. N. lat. 45° 50'. W. long. 124°.

QUICKSET, in Agriculture, a term generally applied to the white, or hawthorn plant, the fets or young plants of which are raifed by nurferymen for fale, for the purpose of planting and forming hedge-fences. The roots of the thorn will, however, anfwer equally well, and in fome cafes much better, as there is a certainty of their being of the right fort, or fuch as have prickles upon them, which does not always happen in ufe the quicksets, as they are liable to diappear when raifed in this method, but which is never the cafe in the root-model. See Fence- Thorn, and White-Thorn.

Young plants of the quickset kind are best raifed in small portions of ground fett apart for them; in which, after they are come up from the feed to fome height, they fhould be transplanted in lines at narrow diftanccs, in a ftraight manner, with small intervals between the rows; where they are to remain from three to five years or more, being annually well cleaned and moulded up. Some, however, transplant them more than once, and think it an advantageous way, but they do well in either method. Well grown plants, with ftout clean items, are the moft proper for planting out as hedge plants.

QUICKSET Hedge, a name given to all forts of hedge-fences which are confituted of any fort of living plants; but more efpecially of thofe of the white-thorn kind. Hedges of this nature compofe the principal fences of this country. In the drier and better forts of foil, thofe of the thorn kind generally prevail; but in moft other situations, thofe of some other forts of plants, according to the particular nature of the soils and expofures. The quicks or quicksets of the thorn forts are commonly fuppofed to form the beft hedges, when planted in the raifed bank or dike method. The manner of placing them out in thefe, is different in different cafes, both in refpect to the form and number of the rows, as well as the diftances of the plants from each other. Some think one regular or irregular row the moft proper, others prefer two ftraight ones; and some fuppofe a few inches diftance from plant to plant the moft beneficial; while others think eight or nine inches to be much better. Strong well-grown quicksets are commonly preferred in all cafes. It is remarked in the Essex Report, by one of the perfofs engaged in drawing it up, that in the
parish of Birdbrook, in the north-east part of it, "some excellent hawthorn hedges have been lately raised, by planting one row only at six inches alder, rather than two rows nine inches or a foot apart. The hedges have not been cut down, nor do they require it, to thicken their bottoms, as they are, at this time, a complete protection against hogs, and in other respects form a beautiful and effectual fence. Nothing can be more evident, it is thought, than that a row of plants let thus, . . . . six inches distant from each other, will form a more complete and effectual fence at the bottom, than an equal number planted thus, . . . . at a double distance, and occupying the same length, but a greater depth of ground upon the hedge row." This reasoning of Mr. Vancouver's, Mr. Young observes, may, for aught he certainly knows, be conclusive, but it strikes him in a different light. It is true, that the plants in each row are, in the latter made, at double the distance from each other than they are in the former; but it is to be observed, that in the double row, the plants are diagonally as near each other as in the single row, and, consequently, there is the same vacant space for any animal to pass through in the single row as in the double; and what must be a great advantage to the latter, the plants will shoot out their branches laterally on the outsides at least, just as those in the single row, and twice as far lengthwise, meeting with no obstruction in their progress. Of course, it is naturally to be concluded, that the double-rowed plantation must form a fence, if not altogether twice as strong and secure, yet vastly stronger and leecher than the single one. He does not, however, presume to set speculation against fact, as he has not seen the hedge noticed above, while Mr. Vancouver has. He has, however, himself planted one in a single row, as above described and recommended; the plants have grown well; the hedge is a good one, but would, he thinks, have been still better, if there had been two rows instead of one, as some others are that he has of that description.

In Suffolck, the quickset hedges at Goodwood are capital, and deserving of every attention, being raised and trained in a most masterly manner. The duke of Richmond planted them about eighteen or twenty years ago. They surround a very considerable farm, and are in a wonderful state of preservation. They form an excellent fence, without the allusion of any ditch, bank, rail, or pale; confit of three rows of white-thorn plants, which spread three or four feet at bottom, but are clipped regularly and gradually to a thin edge at top; the shoots are so numerous, and trained with such care, that even in winter, without a leaf, the thicknes is uncommon. By the young hedges now in training, it appears that one method pursued has been to plant the central row first, and when that is well established, to add another on each side of it; at least this is done in these new hedges. They are kept in a state of garden neatness; the branches are drawn into the line defined, by being tied with mat, or other lines, and the clipping done with the exact attention; the union of the hedges with the gate-poles is close and perfect, and as to gap, &c., there is no such thing. How they have been preferred from cattle, but especially from sheep, is marvellous, if either are ever allowed to enter these closes; an attention never ceasing, and a boundless expense, so far as necessary, must have been exerted. They cannot be recommended to the imitation of farmers on account of the trouble and expense of them, but they are beautiful as an object to the farming eye, and for their perfection, they merit all that can be said of them.

On the Willburton farm in the same district, there are some very good quickset hedges, which were planted about twenty-three years ago; the quick was set about two inches alder, and sedge; they are cut twice in a year; are four and a half feet high, and two feet thick. There is very little ground lost by the hedge, as it occupies only four feet. The same excellent fort of quickset hedges has also been made in some other places.

Here two rows of white-thorn plants are common, which are put on the bank of the ditch, care being taken not to have them too near it, for fear of its draining them too much and preventing their growth. In some districts, where the cultivation is principally of the arable or village kind, and in exposed upland situations, there is frequently a great prejudice and objection to the introduction and formation of any fort of live hedges, whether of the quickset or any other description, as they take up much space, harbour birds and insects, greatly hide the grain, and tend to promote blight, rust, and mildew, by preventing the free circulation of air. Also in bleak exposures they are not raised without great difficulty. Such objections, however, speedily vanish when they are kept sufficiently low and well cut in and trained on the sides. See Hedge and Fence.

QUICKSILVER, a very ponderous fluid mineral, by the chemists called mercury. For the method of gaining, preparing it, &c. with its properties, uses, &c. see MERCURY.

Quicksilver, when rubbed down and blended with unctuous matters, forms a sort of ointment, which is useful in the curing of different diseases of the cutaneous kind, as well as in delirious lice and other vermin that infect animals of different kinds, which form the live-stock of the farmer.

It has also been rated on the authority of Mr. Bradford, as communicated to the Society for the Encouragement of Arts, &c. to have been found useful in its crude state in destroying insects on fruit trees. On a plum-tree he made the following trials; he took a small awl, and pierced, floping, through the rind, and into part of the wood of the branch, but not to the heart or pith of it; and poured in a small drop or two of the quicksilver, and flopt it up with a small wooden plug, made to fit the orifice; and the result was, he says, that the insects all drop off from that branch the next day; and in a day or two more, from off the other branches of the tree, without any other puncture; and the tree continued in full vigour, and throve well all the summer after. Encouraged by this success, he next tried it upon an honey-fucks, the leaves of which were quite covered with them; and here he scraped away the top of the ground with a trowel, and run his awl, in the same floping manner, into the main stem, just above the roots; but with the same caution as above, not quite to the inner pith; and the success was the same as before. The insects all drop off dead the next day after the experiment was made.

These trials are said to have been confirmed by other experiments; but they are still in want of full and satisfactory confirmation.

QUICKSILVER, Virgin. See Virgin.
QUICKSILVER Water. See Water.
QUICKSTADT, in Geography, a town of Norway, in the province of Aggerhus; 42 miles N. of Christiania.
QUICK-WORK, in a Ship, is a general name given to all that part of a ship which is under the surface of the water, when the ship is laden for a sea-voyage. The term is also applied, occasionally, to that part of the side which is above the water-line, and which is usually painted with trophies, &c. on the outside. Falconer.

Quick-work is likewise applied to the frakes that flut in the inlets, between the spars and the clamps.
**QUID, What, in the Schools, is used to denote the definition of a thing. It is thus called, because the definition answers to the question, quid est? what is it? Hence we have two kinds of quids; nominal, quid nominis; and real, quid rei.

Quid juris clamat in Lavo, a writ that lies where I grant the reversion of my tenant for life by fine in the king's court, and the tenant will not attorn; then the grantee shall have this writ to compel him. This writ seems to be obsolete, since the fourth and fifth of Anne. See Attornment.

Quid pro quo, q. d. what for what, denotes the giving of one thing of value for another; or the mutual consideration and performance of both parties to a contract.

Quid pro quo, or Qui pro quo, is also used, in Physic, to express a mistake or cheat of an apothecary, in administering one medicine for another; or in using an ingredient in a composition different from that prescribed.

A northern physician, in a printed thesis on quid pro quo, owns ingeniously, that they are very frequent. He distinguishes very accurately a great variety of kinds of quid pro quo; some with regard to the operation, others with regard to the subject; and others with regard to their form, or effects. The first comprehends the quid pro quo of the physician; the second, those of the patient; the third, those of the apothecary.

Quid Leo, a term which signifies the loss of the ruminate power in animals of the live-flock kind. It is mostly produced by local weaknesses of the stomach, caused by eating improper coarse kinds of food in large quantities, or other similar means. It may be heit restored by the use of strong acids of the vegetable and other kinds, and its return prevented by strong bitter infusions, as thole of gentian, bark, &c. See Cud.

QUIDDEINEN, in Geography, a town of Prussia, in Oberland; 6 miles S.E. of Holland.

QUIDDENY, Quiddany, (of the Latin cydonium, or cydoniutum,) a conferve of quinces, called also marmalade.

QUIDDITY, Quidditas, in the Schools, a word of the fame significication with essence. The name is derived hence, that it is by the essenee of a thing that it is tate quid, such a quid, or very thing, and not another. When upon seeing, or hearing, the name of a thing, with whose nature, &c. we are unacquainted, we ask, Quid est? What is it? We mean no more by the interrogation, but that we desire to have its nature and essence explained by a definition. Whence quiddity is usually defined the essence known or expressed in a definition.

And hence what is essential to a thing is said to be quiddity, as quidditas, knowledge, &c.

QUIEBOU, in Geography, a town of France, in the department of the Charente; 6 miles S.W. of St. Lo.

QUIC, Michael, L.P., in Biography, a learned Dominican monk, who flourished in the latter part of the 17th and in the 18th century, was born in the year 1661. He received a liberal education, having been instructed in classical learning at his native place, and he was then sent to study philosophy at the college de Plessis, at Paris. At twenty years of age he determined to renounce the world, and took the habit in a Dominican convent. Here he studied with uncommon industry and proportionate success, the Greek, Hebrew, and Arabic languages, rhetoric, divinity, the sacred scriptures, and ecclesiastical antiquities. In the year 1692 he first appeared as an author, by publishing “A Defence of the Hebrew Text and the Vulgate Version,” against a work, entitled “The Antiquity of Time restored,” written by father Pezon. The latter having published a reply, Quien answered in a work entitled “The Antiquity of Time exploded.” He next attacked him in “Remarks” on his “Attempt at a literary and historical Commentary on the Prophets,” printed in the Memoires de Trevoux, for March 1711. During the following year he published “S. Joannis Damasceni Opera quae extant Gr. et Lat.” in 2 vols. fol. accompanied with dissertations abounding in erudition. He intended to have given a third volume, containing fuch pieces as had been falsely attributed to that father, but it was never sent to the press. The fame fortune has attended his labours on “The Works of Leo of Byzantium,” to which he had paid a considerable share of attention. Towards the close of his life he entered into a controversy with father Courayer, concerning the validity of the ordinances of the church of England, in which the palm of victory was given to his opponent. Le Quien died in 1753, at the age of 72 years, respected for his piety, and uniform correctness of conduct. He was author of various “Differtations” to be found in Defmaules “Memoires de Lettre et d’Histoire,” and the “Mercure de France.” At the time of his death he was engaged in printing the most considerable of his works, relating to the ancient and present state of the eastern churches. “His plan includes the whole of his churches, under the four grand patriarchates of Constantinople, Alexandria, Antioch, and Jerusalem; presents a geographical description of each diocese, and of the eiscopal cities, and then gives a particular account of the origin and establishment of the churches, their extent, their jurisdiction, their rights, their prerogatives, the succession and order of their bishops, their political government, the changes which they have undergone,” &c. As the author did not live to finish his work, it was published with additions, in the year 1740, under the title of “Michaelis le Quien Orients Christianus, in quatuor Patriarchatus digestus, quae exhibeat Ecclesiae, Patriarchae, ceterisque Prefules Orientis,” &c. in 3 vols. fol. Morei.

QUIENFIORD, in Geography, a bay on the coast of Norway; 27 miles N. of Christianland.

QUINS, a river of Norway, which runs into the sea, 18 miles N. of Cape Lindefefs.

QUIESCENT, something at rest.

QUIETISM, in Ecclesiastical History, the sentiments of the Quietists, a religious sect, which made a great noise towards the close of the 17th century.

Mohinos, a Spanish priest, who died at Rome in the prison of the inquisition, pales for the author of Quietism; and yet the Illuminati in Spain had taught something like it before.

A sect similar to this had appeared at Mount Athos, in Thessaly, towards the close of the fourteenth century, under the appellation of Hesychists, which denotes the name with Quietists. These were a branch of the Myzizez, (which see,) or those more perfect monks, who, by a long course of intense contemplation, endeavoured to arrive at a tranquillity of mind entirely free from every degree of tumult and perturbation. These Quietists, in conformity to an ancient opinion of their principal doctors, (who imagined that there was a celestial light concealed in the deepest retirements of the mind,) used to sit every day, during a certain space of time, in a solitary corner, with their eyes eagerly and innoveously fixed upon the middle region of the belly, or navel; and boasted, that, while they remained in this posture, they found, in effect, a divine light beaming forth from the soul, which diffused through their hearts inexpressible sensations of pleasure and delight. To such as inquired what kind of light this was, they replied, by way of illustration, that it was the glory of God, the same celestial radiance that surrounded Christ.
Christ during his transfiguration on the mount. Barlaam, a monk of Calabria, from whom the Barlaamites derived their denomination, styled the monks, who adhered to this institution, Maffalians and Euchites: and he gave them also the new name of Umbilicants. Gregory Palamas, archbishop of Thessalonica, defended the cause against Barlaam, who was condemned in a council held at Constantinople in the year 1341.

The name is taken from a sort of absolute rejîl, and inaction, which the soul is supposed to be in, when arrived at the state of perfection, which is the language is called the unitive life. To arrive at this, a man is first to pass through the purgative way; that is, through a course of obedience, inspired by the fear of hell: hence he is to proceed into the illuminative way, before he arrives at perfection.

The sentiments of the Quietists, with regard to God, are wonderfully pure and disinterested. They love him for himself, on account of his own perfections, independently of any rewards or punishments: the soul acquiesces in the will of God, even at the time when he precipitates it into hell; inasmuch that instead of stopping him on this occasion, B. Angello de Foligny cried out, "Ha! Ha! Lord, to call me into hell: do not delay if thou hast abandoned me: but finish my destruction, and plunge me into the abyss!"

At length the soul, after long travail, enters into rest, into a perfect quietude. Here it is wholly employed in contemplating his God: it acts no more, thinks no more, defines no more; but lies perfectly open, and at large, to receive the grace of God, who by means thereof drives it where it will, and as it will.

In this state it no longer needs prayers, or hymns, or vows; prayers where the spirit labours, and the mouth opens, are the lot of the weak, and the imperfect: the soul of the faint is, as it were, laid in the bosom, and between the arms of its God, where, without making any motion, or exerting any action, it waits, and receives the divine graces. It then becomes happy: quitting the existence it before had, it is now changed; it is transformed, and, as it were, funk and swallowed up in the Divine Being, insomuch as not to know or perceive its being distinguished from God himself. Fenel. Max. des Saints.

QUIETISTS, the disciples of Mich. de Molinos; or the adherents to the opinions delivered in the article Quietism. The sentiments of Molinos were contained in a book, which he published at Rome in the year 1681, under the title of the "Spiritual Guide," in consequence of which he was cast into prison in 1685, where he was soon obliged to renounce, in a public manner, the errors of which he was accused; and this solemn recantation was notwithstanding followed by a sentence of perpetual imprisonment, from which he was in an advanced age delivered by death, in the year 1696. Molinos had a considerable number of disciples in Italy, Spain, France, and the Netherlands. One of the principal patrons and propagators of Quietism in France, was Marie Bouvier de la Motte Guyon, a woman of fashion, remarkable for the goodness of her heart, and the regularity of her manners; but of an unfezzled temper, and subject to be drawn away by the seduction of a warm and unbridled fancy. This female apostle of mysticism derived all her ideas of religion from the feelings of her own heart, and described its nature to others as she felt it herself. Accordingly, her religious sentiments made a great noise in the year 1687; and they were pronounced unfound, after accurate examination by several men of eminent piety and learning, and professedly confuted, in the year 1697, by the celebrated Boeufet. Hence arose a controversy of great moment, between the prelate last mentioned, and Fenelon, archbishop of Cambrai, who seemed disposed to favour the religious life of Madame Guyon, and who, in 1697, published a book, cited in the last article, containing several of her tenets. Fenelon's book, under the title of "Contre le Boeufet," was condemned by the year 1699, by Innocent XII. and the sentence of condemnation was read by Fenelon himself at Cambrai, where he exhorted the people to respect and obey the papal decree. Notwithstanding this seeming acquiescence, the archbishop perilled, to the end of his days, in the sentiments which, in obedience to the order of the pope, he retracted and condemned in a public manner. See the article Fenelon.

QUIETO, in Geography, a river of Iliria, which runs into the Adriatic, two miles W. of Btaita.

QUIETUS, freed or acquitted, a term used by the clerk of the pipe, and the auditors in the exchequer, in their acquittances or discharges given to accomptants, which usually conclude with the words at sine reeectis quietus; which is called a quietus ctit.

A quietus ctit granted to a sheriff, discharges him of all accounts due to the king.

QUIFORO, in Geography, a district of Africa, on the Gold Coast.

QUIGNONES, Francis de, in Biography, an eminent Spanish cardinal in the 16th century, who embraced the religious life at an early age, in a monastery of Franciscans, and subsequently afforded such evidence of superior talents, that he was elected general of his order in the year 1522. He obtained the office of confessor to Charles V. and upon the capture of Rome by the imperial army in 1527, and the imprisonment of pope Clement VII. in the castle of St. Angelo, his services were solicited by that pontiff, in negotiating for his liberty, and were afterwards rewarded with a cardinal's hat. After this, he was by the same interest nominated bishop of Cauria, and lent in the capacity of apostolical legate into Spain, and the kingdom of Naples. He died in the year 1549. He was author of a reformed breviary printed at Rome in 1536, which met with the approbation of popes Clement VII. and Paul III. but it was afterwards suppressed by Pius V.; hence it has become rare, and is sought after by collectors. Several spurious editions have been printed at different times. It is inserted in the "Annales Minores" of Wadingius, and in the second edition of Joly's treatise "De Reformandis Horis Canoniciis."

QUIJUBATUI, in Ornithology, the name of an American species of parakeet.

It is of the size of a lark, and in general of a yellow colour. Its eyes are black, and its head grey. The edges of its wings are of a dusky green, and its tail long and yellow. It is a very beautiful bird, and very easily tamed. See Psittacus Guarouba.

QUIKNE, in Geography, a town of Norway, in the province of Bergen; 105 miles N. of Christiania.

QUIL, in Zoology. See Quirfel, and Viverra Mungo.

QUILAQUIL, in Ornithology, the name given by the people of the Philippine islands to a very beautiful species of parrots, which is commonly found wild in the woods there. It is all over of a fine green colour, and is smaller than the common parrots, and has a broad black bill, and black legs. It is a very wild bird, and will not learn any thing.

QUILATE, in Spanish and Portuguese Coinage, a term used for carat; which see.

QUILEA, in Geography, a sea-port town of Peru, near the Pacific ocean, which gives name to a fertile valley, in the jurisdiction of Arequipa. S. lat. 16° 47'.

QUILICI,
QUILICI, Gaetano, in Biography, an Italian opera- 
figer, with a bale voice: a good musician, who arrived here in 1759, during the performance and opera regency of the Mattei. He continued to perform on our lyric stage near thirty years, and is, we believe, still living in London, we fear, in penury and obscurity. Since quitting the stage, he has supported himself, a bed-ridden wife, and an ideot 
on, by teaching to sing, and has made some admirable scholars.

QUILIMANCY, in Geography, a river of Africa, 
which runs into the Indian sea, 26 miles S. of Melinda. S. lat. 3° 16'. E. long. 40° 16'.—Also, a sea-port town of 
Africa, in the kingdom of Melinda, at the mouth of the 
before-mentioned river, belonging to the Portuguese. S. lat. 3° 16'.

QUILLAMNE, a town of Africa, in Mozambique. 
S. lat. 18° 15'. E. long. 37° 30'.

QUILLAJA, in Botany, a genus of plants found in 
Chili, and described by Molina. Jull. 444. Lamarck II. 
Hetr. t. 774.—Clafs and order, Monoezia Dodecandra. 
Nat. Ord. uncertain. 
Eff. Ch. Male, Calyx five-cleft. Corolla none. Sta- 
mens twelve, or more.

Female, Calyx five-cleft. Corolla none. Germs five, 
superior, opposite to the segments of the calyx. Styles five. 
Capsules five, erinaceous, of two valves, and one 
cell. Seeds numerous, oblong, inserted into the bottom of 
the capsule, dilated and winged at the summit.

Such is the character made out by Juffieu, from 
the publications of Molina and Frezier, and from specimens 
of the fruit, brought to Europe by Dombey. They belong 
to a tree, whose bark has a foapy quality. The leaves 
are alternate, simple, evergreen. Flowers axillarv.—The ge- 
nerus appears akin to the Magnoliso of Juffieu, but whatever 
it may be, the name is barbarous and quite inadmissible; 
only tolerable for a time, till some botanist, furnished with 
hetter materials to define the genus, shall be entitled to give 
it a more classical appellation. Juffieu remarks, that another 
plant of Dombey's appears to belong to the above genus. 
This is a tree referred by him to Dioecia lepofandria, whose 
fruit is called Gao colorado, and which is the fame with the 
"Loque, or Peruvian tree with five capsules," of Josep de 
Juffieu, whose branches, according to his manuscript ac- 
count, are fo long and pliant, as to be twifled into cords, 
serving, in the province of Cufco, for the support of hang- 
ing bridges.

QUILLALA, in Geography, a town of Chili, on the 
Aconcagua; 30 miles E.N.E. of Valparayso. 

QUILLAN, a town of France, in the department of 
the Aude, and chief place of a canton, in the district of Li- 
moux; 10 miles S. of Limoux. The place contains 15 68, 
and the canton 9195 inhabitants, on a territory of 272½ 
kilometres, in 22 communes. N. lat. 42° 52'. E. long. 2° 16'.

QUILLAYACU, a town of Peru, in the diocese of 
Lima; 60 miles E.N.E. of Guanaco. 

QUILLE, a town of Sweden, in the diocese of 
Gotland; 23 miles N. of Uddevalla. 

QUILLEBEUF, a town of France, in the depart- 
ment of the Eure, and chief place of a canton, in the district of 
Pontaudemer, feated on the Seine; eight miles N. of 
Pontaudemer. The place contains 1200, and the canton 
7272 inhabitants, on a territory of 107½ kilometres, in 16 
communes. N. lat. 49° 29'. E. long. 0° 38'.

QUILLET, Claude, in Biography, born at Chiron, 
in Touraine, about the year 1602, was brought up to me- 
dicine, which he practised some years, till he was obliged to 
quit the country on account of his opposition to a measure of 
Richelieu, which is thus narrated. Quillet was at Loudun 
at the time that Loubadement, a creature of the cardinal, 
was sent thither to take informations respecting the pretend- 
ed poiffession of some ruins by the forceries of Urban GRAN- 
DIER (see his article), an imposture which Richelieu thought 
fit to favour. The counterfeit Satan one day threatened, that 
on the Morrow he would lift up to the roof of the church 
any one who should presume to call his power in question. 
A large company appeared on the next day with M. Loubad- 
emont, when Quillet, who also was present, challenged the 
devil to keep his word. To the surplice of the superstitious 
who had met on the occasion, nothing followed, but the 
challenger found to his cost that he had given offence to a 
mightier power than Satan, and felt it necessary to quit 
Loudun in haste, and retire to Italy. He went to Rome, 
and was engaged as secretary to the French ambassador at 
that court. He probably returned to France with that mi-
nilier, after the death of Richelieu, and in 1655 he publish- 
ed at Leyden, under the name of Calvidias Lexit, the 
poem by which he is chiefly known, entitled "Callipedia 
devi de pulcheria Proliis habendae ratione." In the first 
edition were some satirical lines against Mazarin. The 
cardinal sent for him, and having gently remonstrated with him 
for treating his friends with levity, promised to give him 
the first vacant abbey. Quillet threw himself at the cardinal's 
feet, asked pardon, assured him he would instantly obliterate 
the offensive lines, and begged, as a sign of his penitence, 
to be allowed to dedicate the poem to him. This was done 
in the Paris edition of 1656, and Quillet became the flatter- 
er of him who had been the object of his satire. He 
died at Paris in 1661, repenting not of his abdation, but 
of the licentious cast of some of his verses. The 
Callipedia has gone through many editions, and has been translated 
into various languages. "It is," says an able critic, "an 
ingenious performance, agreeably varied by fable and epifode, 
but frivolous in its main topic, and in its rea'oning. Its 
details are frequently loose and inflammatory, and that a car- 
dinal should have allowed it to have been dedicated to him, is 
a proof how little regard was paid, at that period, to the 
rules of decorum. The verification, though generally free 
and flowing, is by no means correct, and the diction is fre- 
cquently impure." Quillet compos'd a version of Juvenal 
in French verse, and a Latin poem in twelve books, entitled 
"Henriados," or the actions of Henry IV. This, with 
other papers, he left to Menage, with 500 crowne to de-
fray the charge of printing them, but the abbe took the 
money, and neglected the conditions.

QUILIGA, in Geography, a country of Africa, in 
Upper Guinea, near the river Maqualbar. 

QUILLOBO, in Botany, a name given by fome to a 
species of ketmia, called also quingombo. 

QUILLOT, Killo, or Killo, in Commerce, a Turkish 
corn measure, weighing, in wheat, about 23 okes, or 60lbs. 
avoiduposis: 4 killos make 1 fortin; 4 ot killo answcr nearly to 1 English quarter. A killo of rice contains 10 
oke, and the oke is 400 drachms.

QUILLOTA, in Geography, a town and jurisdicticn 
of Chili. The town does not contain above 100 families, but 
those scattered over the country exceed 1000.

QUILLY, a town of France, in the department of 
the Lower Loire; 7 miles N. of Savenay.

QUILOA, a country and kingdom of Africa, situated 
near the eafi coast, near the mouth of the Coavo, about 
180 miles from north to south; but the extent inland towards 
the west is unknown. This country was first discovered by 
the Portuguese, in the year 1498. The king and his sub-
jects
fects are Mahometans; the latter partly black and partly tawny. They all speak the Arabic and several other languages, which they learn from the nations they traffic with. Their dress is that of the Arabian Turks: the women especially affect finery, with variety of ornaments about their necks, arms, wrists, and ankles; particularly bracelets made of ivory, curiously wrought, which upon the death of a parent, husband, or near relation, they break in pieces, in token of sorrow, whilst the men express theirs by having their hair, and abasing from food. The capital of the kingdom is situated on an island near the mouth of the Coque, and is said to be large, rich, and well built. The houses are of stone and mortar, handsome, and after the Spanish manner. They are several stories high, and have each a pleasant garden behind, well watered and cultivated, here being plenty of springs of fresh water. The houses are finely furnished within, and terraces on the top, with a kind of hard clay, and the streets so narrow, that one may easily leap from one side to the other. On one side of the town is the citadel, where resides the Mahometan prince. It is adorned with lofty towers, and surrounded with a ditch and other fortifications. It hath two gates, one towards the port, whence one may see the ships falling in and out; the other looking towards the land. The country about Quilao, though low, is yet very pleasant and fertile in rice and millet, fruits and good pastures; so that they breed abundance of cattle, besides poultry of all sorts, both wild and tame. They have fish likewise in great plenty, and very good. The climate is likewise affirmed by most travellers to be very temperate and healthy; Sanut being the only author we know of who hath ventured to affet the contrary in all these respects. S. lat. 8° 33'.

QUILONNE, a province of Africa, in the kingdom of Saba.

QUILOVIA, a small island in the Indian sea, near the coast of Africa. S. lat. 13°.

QUITAINEN, a town of Prussia, in the province of Oberland; 8 miles S.E. of Holland.

QUITAO, one of the Laccadive islands, in the Indian sea. N. lat. 12°. W. long. 72° 45'.

QUILTING denotes the operation of weaving a fort of coat or texture, formed of the strands of rope, about the outside of any vessel, to contain water, &c. as a jar, cask, bottle, &c.

QUIMICHPATLAN, in Zoology. See Scinurus Vo- lucella.

QUIMINATIN, in Geography, a small island in the sea of Mindoro. N. lat. 10° 55'. E. long. 120° 40'.

QUIMIRI, a town of Peru, in the diocese of Lima; 40 miles N.E. of Nacca.

QUIMO, a small island on the east side of the gulf of Bothnia. N. lat. 63° 17'. E. long. 21° 52'.

QUIMPER, a city of France, capital of the department of Finisterre, and chief place of a district, feated on the Oder; before the revolution the see of a bishop, the seat of a governor, an admiraltry, &c. The place contains 60,808 inhabitants, on a territory of 50 kilometres, in seven communies. N. lat. 47° 50'. W. long. 4° 5'.

QUIMPERLE, a town of France, and chief place of a district, in the department of the Finisterre. The place contains 4162, and the canton 9128 inhabitants, on a territory of 125 kilometres, in 15 communies.

QUIN, Dr., of Dublin, in Biography, an eminent physician, and one of the most enlightened dilettante musicians with whom we have ever been acquainted. This gentleman, who, during his travels, resided in Italy some years, had heard and studied music with such taste and intelligence, that his opinions and conversation on the subject were equally entertaining and instructive. He resided in Dublin at the time of Handel’s arrival in that city, 1742, and perfectly remembering his performance, perfect, and manners, in 1788 wrote as word, that “he (Handel) was received in Ireland by persons of the first distinction with all possible marks of esteem, as a man, and admiration as a performer and composer of the highest order.” And adds, “the Mefiffah, I am thoroughly convinced, was performed in Dublin for the first time, and with the greatest applause. Mrs. Cibber and Ignatia Avolio were the principal performers. Thefe, with the affilience of the clorors of St. Patrick’s cathedral and Christ-church, formed the vocal band; and Dubourg, with several good instrumental performers, composed a very respectable orchestra. There were many noble families here, with whom Mr. Handel lived in the utmost degree of friendship and familiarly. Mrs. Vernon, a German lady, who came over with King George I. was particularly intimate with him, and at her house I had the pleasure of seeing and conversing with Mr. Handel; who, with his other excellencies, was poifled of a great Rock of humour; no man ever told a Jolly with more. But it was requisite for the hearer to have a competent knowledge of at least four languages: English, French, Italian and German; for in his narratives he made use of them all.”

QUIN, JAMES, was born in London in 1693. He was the son of an Irish gentleman, and received his education in the capital of that country. His father had, ignorantly, married a woman supposed to be a widow; whole husband, after a long absence, returned and claimed her. The subject of this article was the offspring of this connection, and was accordingly illegitimated, and upon his father’s death, in 1710, was left almost destitute. For want of education he was, at the age of twenty-one, without a profession, and was under the necessity of appearing on the stage at Dublin, in the very lowest characters. He displayed, however, rising talents, which induced a friend to advise him to attempt some better parts in London, and he was accordingly admitted into Drury-lane company in 1715. After the experience of a year or two, he entered himself under Rich at Lincoln’s-Inn theatre, where he continued to perform during seventeen years. He was allowed, by the most competent judges, to shine both in tragedy and comedy. His utterance was weighty and impressive, which, however, was accompanied with various defects. He was, from caustics not well ascertained, continually changing from one theatre to another, and perhaps he may be ranked among that number with whom it was difficult to keep terms. His passions were strong, his temper irritable, and his language often coarse. He was of convivial habits, and, it has been said, grossly attached to the pleasures of the table. There was, however, a fund of generosily in his temper, which showed itself in many sentiments, and, occasionally, in benevolent actions. The circumstance of his giving a 1000 to the poet Thomson, when he was under an arrear for debt, has often been told to his honour. It was the commencement of a strong friendship between them. After Thomson’s death, he appeared in that poet’s tragedy of Coriolanus, and spoke a prologue, written on the occasion by lord Lyttleton, with a pathos that did honour to his feelings. His last performance was the favourite part of Falstaff, for the benefit of his friend Ryan in 1753. He now retired to Bath, where his fund of anecdote, and strong pointed sense, rendered his company much sought after. He had good breeding, which fitted him for the highest societies, when he chose to act the gentleman; and his frankness and coarseness were frequently
Quin, in Geography, a village of the county of Clare, Ireland, where are the remains of a monastery, which was founded for Franciscan friars in 1402, and repaired by the Roman Catholics in 1604. Bishop Pococke speaks of it as one of the finest and most entire monasteries he saw in Ireland. It is situated on a fine stream, with an affluent of several streams to the church; at the entrance one is surprised with the view of the high altar, entire, and of an altar on each side of the arch of the chancel. The building is quadrangular, with piazzas supported by a number of pillars; there are apartments on three sides of the cloisters, with a vaulted room under them all. A round tower and some other ruins are adjoining. Quin is 15 miles from Limerick, on the road to Galway, and about 180 miles W.S.W. from Dublin. Archdall's Monastic. Carlisle.

Quina Folia, in Botany. See Lea.

Quinabaug, in Geography, a river of America, formerly called "Mobegan," which rises in Brimfield, Massachusetts, and is joined at Oxford by French river, which has its source in Sutton, Worcestor county. It runs a southerly course, and discharges itself into Shetucket, about three miles above Norwich Landing, in Connecticut. In the first part of its course it furnishes many good mill-sites; as it advances, the intervals in many places are wide, and afford a most excellent soil.

Quina-Quina, in Botany, a Peruvian name, generally applied to the Peruvian bark. (See Cinchona.) Jussieu, however, in his Gen. Pl. 366, informs us, that it properly belongs to a tree, nearly if not entirely agreeing in genus with Myropermum of Jacquin, or Myroxylon of Linnaeus. (See the last-named article.) An account of the Quina-quina may be found in the Memoires de l'Acad. des Sciences for 1738, p. 237.

Quinaria, so called by Loureiro, Fl. Cochinch. v. 1. 272, from the prevalence of the number five in the parts of fructification, is the Wampi or Wampi of the Chinefe, now established as a genus by the name of Cookia. (See that article.) This plant paffed long, in the gardens of England, for Guarea triechioides, according to the observation of the late Mr. Dryander.

Quinarium, Quinary, in Antiquity, a little Roman coin, equal to half the denarius. See Coin.

The quinary was properly the Roman halfpenny. Medalists indeed use the term quinary in the general for a medal of any matter, not exceeding the size of our sixpence; but F. Chamillard, in an express dissertation, flues this to be an abuse. The silver coins, current under the republic, he shews, were two: the one weighing a drachm, and called denarius, as containing ten alies; the other weighing half a drachm, and called quinarius, as containing five alies: which coins continued on the same footing as the emperor.

Hence the origin of the word quinarius: and hence, in propriety, it is only the silver medal of the weight of half a drachm that the name belongs to; the Romans having never given it to any other species of the same size with it. It is only by way of analogy, therefore, that the moderns apply it to the medals of gold, or copper, of the same size with the silver quinarius; those of gold being fixed at a value much above, and those of bract much below five alies.

The only relation between these quinarii is, that the gold quinary is the half of a gold medal, as to weight and value; and the bract quinarius half a bract medal, as the silver quinarius is half a silver one.

Hence a feries of quinarii should seem at least a necessary in the cabinets of the curious, as the feries of great medals; they being all equally different species of money, which teach us how many kinds of pieces there were of any metal current in commerce.

Add to this, says our author, that the quinaries were of a finer and more finished coin than the other medals, being wrought by the hands of the masters; which seems owing to the nicety required in engraving whole figures in too small a compass. He adds, that though quinaries are very scarce, yet M. the duke of Maine had almost a complete set of them.

Quinault, Philip, in Biography, a French poet, was born in 1636, probably in a low condition; though while some fay he was the fon of a baker, others maintain that he was ferved from a family of confluence at Paris. He had, however, very few advantages of education, but he was soon found to possess a talent for poetry and the belles lettres. Before the age of twenty he brought out three pieces on the stage; and for a number of years, he continued to produce dramatic works of different kinds, which were much applauded by the public voice; but some of which drew upon the author the fates of Boileau, who carried the matter so far as to injure his own reputation. Quinault now associated himself with Lulli in the composition of operas, and displayed an excellence in lyric poetry, or that adapted to music, which placed him beyond competition in that branch, and has ranked him among the distinguished characters of the age of Lewis XIV. Nothing, it is allowed, can be more tender, delicate, and ingenious, than the turn of his fongs and love-dialogues; and no one has more happily accommodated the melody of French verse to musical expression. His "Armida" and his "Atly" are spoken of as master-pieces of their kind. Notwithstanding the high reputation which he enjoyed as a poet, he applied himself to the study of the law, and eventually made his fortune by marrying the rich widow of a merchant, to whom he had been useful in his profession. After this, he purchased the place of an auditor in the chamber of accounts. He was received into the French academy, and, in the name of that society, harangued the king on his return from the campaigns of 1675 and 1677. He died in 1688, having enjoyed a pension from Lewis XIV. several years previously to his decease. In his last illness he was extremely penitent, on account of his having devoted his talents too frequently to the excitement of the licentious passions. He left a family of five daughters, and was esteemed in society attentive, polite, and mild. Besides his numerous pieces for the stage, he wrote occasional poems. His works were printed at Paris in 5 vols. 12mo., 1739, and again in 1778.
Quinault's apprenticeship to poetry was served under Tristau l'Hermite, by being his domestic. The lessons of Tristau were probably of some use to him, as that author had had long experience in theatrical matters; but Quinault owed still more to nature: as before he was twenty years old, he had distinguished himself by several pieces for the stage, which had considerable success; and before he was thirty, he produced sixteen dramas, some of which were well received by the pit; but not all equally. It is supposed that some of these early pieces prejudiced Boileau against Quinault early in his career. There was neither regularity in the plan, nor force in the style: romantic lovers and common-place gallantry, in scenes which required a nervous pencil and vigorous colouring. There were defects not likely to escape the laird of the French Juvenal. He covered the young poet with ridicule; reproached him with the affected soft and languishing dialogue of his lovers, by whom even I hate you was said tenderly.

Quinault, born with great sensibility, was so wounded by his severity, that he applied to the magistrates, not only to silence Boileau, but oblige him to remove his name from his satires; but the attempt was vain. His enemy insulted him still more cruelly by an epigram on the subject.

"Peace! peace! my friend—

If from the public thou'dl avoid disgrace,

From thy own works, not mine, thy name efface."

It was not till after Quinault was inflamed by Lulli to write for the opera, that he silenced all his enemies, except Boileau and his party, who envied him his success. The French nation knew no better music that that of Lulli, and thought it divine. Quinault's was thought of secondary merit, till after his decease; and then, in proportion as the glory of Lulli faded, that of Quinault increased. Voltaire, in the first edition of his "Siecle de Louis Quatorze," in 1749, seems to have been the first who spoke out on the subject; not forry, perhaps, to lower Boileau a little in the eyes of the public. He there says, that "Quinault was celebrated for his beautiful lyric poetry, and for the gentleness with which he opposed the unjust satires of Boileau. His poetry was greatly superior to the music of Lulli. It will always be read; and Lulli, except in a few of his recitatives, can no longer be supported. However, it was long believed that Quinault entirely owed his favour to Lulli: Time appreciates all things."

After this, his writings began to be examined and felt; and of late years, his name is never mentioned by his countrymen with contempt. His operas, though admirable to read, are all calculated for modern music; and are obliged to be new written, ere they can be new set, even in France. Marmontel, who had modernized several of them for Piccini to set in 1788, gave M. Laborde a dissertation on the dramatic writings of Quinault for music; which is published in the fourth volume of his "Essai sur la Musique."

He begins by asserting that Quinault was the creator of the French opera upon the most beautiful idea that could be conceived: an idea which he had realized with a superiority of talent, which no writer has since approached.

His design was to form an exhibition, composed of the prodigies of all the arts; to unite on the same stage all that can interest the mind, the imagination, and the senses. And this illusive theatre Voltaire has admirably described:

"Il faut fe rendre à palais magique," &c.

"Hatfe to the magic palace, where abound

The joys sublime of verse, of dance, and sound;"

Where bright illusion fascinates the sight,

And fire-notes the enchanted ear delight;

Where all the plastic powers of art are shewn,

And joys unnumber'd are combin'd in one."

For this purpose a species of tragedy is necessary, that shall be sufficiently touching to move, but not so audacious as to relish the enchantments of the arts that are necessary to embellish it. Historical tragedy, in its majesty and gloomy simplicity, cannot be sung with any degree of probability, nor mixed with festivals and dances, or be rendered susceptible of that variety, magnificence, show, and decoration, where the painter and the machinist ought to exhibit their enchantments.

In Italy, where genuine tragedy has no theatre appropriated to its use, a people passionate for music have permitted Regulus, Themistocles, Alexander, and even Cato himself, to utter their speeches in song; but a people, whose taste ought to be more severe, and more delicate, as to probability, having for comparison the school of Corneille and Racine, would have been very unwilling to substitute the recitative of Lulli to the declamation of Baron. Melody itself is a fabulous and magical language; and in a theatre where all is prodigy, it seems consistent that the manner of speaking should be that of enchantment as well as the recitative of Lulli to the declamation of Baron. When once it is settled that all the characters converge in a musical language, no other is expected, and the audience is soon reconciled to it. But all this is to prove that the French alone are right, and Italy and all the rest of the world wrong as to the musical drama. The rift of Europe is tired and ashamed of flying gods and goddesses, and have long since surrendered mythical wonders both in poetry and music to their children. But all people are thought barbarians, who do not implicitly adopt the taste and fashions of France.

But to return to Quinault, whom all the wits of the time tried to write down. Ignorant of music and its powers, they thought Lulli always right, and the poor, modest, unpretending Quinault always wrong. Pottier has long discovered the converse of this assumption to be the truth. Quinault's great mistake and misfortune, says La Harpe, was the calling his pieces tragedies, and not operas. He would not then have been regarded as a rival of Racine, or have offended classical hearers or readers with the little resemblance these compositions had to Greek and Roman dramas, or to the genuine tragedies of the moderns.

Voltage in Gardening, the common name of a tree of the apple kind. See Pyrus Cydonia.

Quince, in the Materia Medica. The fruit of the quince is alluring and flamboyant; and its expressed juice, in small quantities, as a spoonful or two, is of considerable service in nausea, vomitings, eructations, and some kinds of alvine fluxes. This juice was formerly ordered in the long, Pharm. to be made into a syrup, called "lyrups cydoniarum," or syrup of quinces, prepared by digesting three pints of the prepared juice with a drachm of cinnamon, half a drachm of ginger, and half a drachm of cloves, on warm ales,
QUI

ashes, for six hours, then adding a pint of red port, and dissolving in the strained liquor nine pounds of sugar. But the only preparation of the quince which it now directs is, a mucilage of the seeds, made by boiling a drachm of the seeds in eight ounces of water, till it acquires a proper consistence. This has been recommended in aphthous affections, and excoriations of the mouth and fauces; however, though it may be a more pleasant mucilage, it is certainly less efficacious than that of the simple quince. Lewis and Woodville.

A useful refringent marmalade is made by boiling the juice with fine sugar to a due consistence, in the proportion commonly of three pints to a pound. The juice of quinces becomes richer, by keeping them for some time, after they are gathered, in a dry airy place.

QUINCE, in Geography, a small island near the S.W. coast of Ireland, and county of Cork; five miles W. of Gally-Head.

QUINCHAC, a small island in the Pacific ocean, between the island of Chiloé and the continent of Chili. S. lat. 43° 32'.

Gen. Ch. Cal. Perianth superior, of one leaf, in four deep, ovate, unequal segments, one larger than the rest. Cor. of one petal; tube funnel-shaped, much longer than the calyx, quadrangular, curved, limb in five lancelate, acute, spreading segments. Stam. Filaments five, very short, inferted into the top of the tube; anthers oblong, the length of the limb. Fil. Germin roundish, style thread-shaped, the length of the tube; stigma capitatum. Peric. Berry (rather drupa) roundish. Seed solitary.

1. Q. chilesis. Willd. n. 1. (Quinchamali lini folio; Feuill. Plantes Médicinales, 57. t. 44.)—Gathered by Feuillée on the mountains of Chili, and by Dombey, among stones on the hills about Lima, flowering in December and January. The root is annual, composed of a few simple yellow fibres. Stem several, prostrate, simple, round, leafy, from four to six inches long. Leaves scattered, foifile, linear, entire, fleshy, smooth, bluntish with a small point. Flowers in simple, terminal, solitary, dense spikes. Corolla green externally, of a fawn yellow within. Seed round, unconnected.—We have taken the generic character, and the description, from Dombey's manuscript, compared with one of his original speciments. The fruit appears to be a drupa, (he terms it baccus,) the size of a hemp-seed, whose coat becomes coriaceous by drying, and separates, along with the permanent calyx at its summit, from the seeds, or nucleus, to whose upper part the corolla remains attached. Jussieu, Lamarec, and Willdenow, having formed their ideas from dried speciments only, took the coat of the drupa for an inferior calyx, and the fritle of these writers conceives the flower to confit of a superior inner calyx, to which he was led by an idea of the affinity of this genus to Tbidium. Willdenow, not adverting to any such affinity, terms the inner calyx of Jussieu, a corolla, which agrees with the opinion of Dombey, the only botanist who has examined the living plant, and by whose authority we are led to consider the true calyx as superior. If we are right, this genus will belong to the natural order of Rubiaceae, notwithstanding its solitary seed. Dombey expressly says it is akin to Morinda.

Feuille relates, that the Indians take a decoction of this plant for internal disorders, especially when they believe themselves labouring under an internal abscess, of which there is no external appearance. The decoction, taken warm, is supposed to break the abscess, and to cause an evacuation of its contents by the usual purges.

QUINCUNX, Quinque unics, denotes a thing that consists of five twelfth parts of another.

QUINCUNX, in Gardening, is the name of a form of planting in which trees are planted by fives, four of them forming a square, and the fifth placed in the middle, thus, and which may be repeated over and over again in one continued plantation, with as many trees in several ranges as may be proper. It was formerly a fashionable mode of planting groves and other regular plantations, but is now less common. It is seen more fully below:

Something of this mode of arrangement has always had a good effect in the disposition of shrubbery plants, &c. though not in the regular order of it, but something nearly so, which gives the shrubs a greater scope of growth, and shews them to greater advantage. It is likewise a mode of planting that is proper in the kitchen-garden, in transplanting many kinds of eculent plants; such as lettuces, endive, strawberries, and even all the cabbage kinds, and many other plants, which gives them a greater scope to grow than if planted exactly square at the same distance from each other.

It is of this kind of quincunx that Cicero speaks, in his Cato Major; and Quintilian, lib. viii. cap. 3.

The modern quincunes, Daviler observes, are made like those of the ancients, except for the fifth tree, which is now generally diffused; so that, being as it were netted, and their avenues viewed by the side of the rectangle, they formed a perfect chequer.

QUINCUNX, in Astronomy, &c. denotes a position, or aspect of the planets when distant from each other a hundred and fifty degrees, or five signs.

QUINCY, in Geography, a town of France, in the department of the Seine and Marne; six miles S.W. of Meaux.

QUINCY, a post-town of America, in Norfolk county, Massachusetts, taken from Braintree; 10 miles S. of Bolton. It contains 1,281 inhabitants, most of whom are farmers; but large quantities of shoes and boots are manufactured for exportation. The town has an episcopal and congregational church.

QUINDECAGON, in Geometry, a plain figure which has fifteen sides and fifteen angles.

The word is formed somewhat irregularly, from the Latin quinde, five, and the Greek exag, ten, and γωνία, angle. Pentagon would be a more regular term.

If the sides be all equal, it is a regular quincunx.

Euclid shews how to inscribe it in a circle, Prop. xvi. lib. 4. And the side of a regular quincunx so described, is equal in power to the half-difference of the side of the equilateral triangle, and side of the pentagon; and also to the difference of the perpendiculars let fall on both sides, taken together.

QUINDECM VIR, XV. VIR. a Roman magistrate, who
who had fourteen colleagues joined with him in the same function.

Under Tarquin the Proud, there were first two magistrates erected to take care of the sacrifices to be performed; these were called daimoniri. Their number, at length, grew to ten, and then they were called decemviri. In the time of Cicero it had reached to fifteen, when they assumed the name of quindicemviri; and though their number grew to forty afterward, yet Servius oberves, on the sixtith of the Aeneid, that their name never after changed, but they still continued to be called quindicemviri.

They were the persons who examined the Sibyls' books, and were the interpreters of them; yet they never did this but by a regular order of the senate, declared by a senatus consultum. They also presided at the sacrifices, and all other extraordinary ceremonies of religion.

On medals, a dolphin joined with a tripod marks the priesthood of the quindicemviri; who, to publish their solemn sacrifices, used on the eve of them to carry a dolphin at the end of a pole throughout the city; that fish being esteemed sacred to Apollo, as the crow was amongst birds.

QUINEPAUGE, or East River, in Geography, a river of America, in Connecticut, which runs a southerly course into the N.E. corner of New Haven harbour.

QUINCEY, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Besançon; nine miles S.W. of Besançon. The place contains 1079, and the canton 11,734 inhabitants, on a territory of 2725 square kilometres, in 36 communes. N. lat. 46° 6'. E. long. 5° 57'.

QUINGOMBO, in Botany, the name given by the people of Congo to a species of ketmia, distinguished by M. Tournefort by the name of the ketmia Brachiflora folio fuscum, fructu pyramidato fulcato, the flag-leaved Brachiflora ketmia, with a pyramidal fulcated fruit.

QUINISDAL, in Geography, a town of Norway, in the province of Christiania; 55 miles W.N.W. of Christiania.

QUINSEXTUM, in Ecclesiastical History, denotes a council held at Constantinople in the year 692; called also the council in Trullo, and by the Greeks Pentabole, q. d. fivesixth; as intimating that it was only a supplement of the two preceding councils. Though, in propriety, Fleury observes, it was a council itself.

Marshall observes, that the fifth and sixth general councils having made no canons relating to the external celebration of divine worship, the government of the church, and the lives and manners of Christians, the Orientals judged it necessary to supply that defect by this; and that the 126 canons falsely attributed to those, were in reality made here. See Trullium.

QUINNET, in Mining, the name of a tool used in the cleaving rocks by means of gunpowder. This is a sort of wedge fitted to the flat side of what is called the gun; that is, a cylindrical piece of iron, only flattened in one part for receiving this, and drilled through. When a proper hole has been made in the rock by the borers, the powder is put in, and then the orifice being stopped by the gun, and that wedged in by this quinnet, the powder being fired by a train communicating with the hole drilled through the gun, exerts all its force on the rock, and splits it in several directions at one explosion. Phil. Trans. N° 167.

QUINOA, in Geography, a town of Mexico, in the province of Culiacan; 50 miles S.E. of Culiacan.

QUINQUAGENERIUS, among the Romans, was an officer in the army, who had the command of a company of fifty men.

QUINQUAGENERIUS was also an officer of policy, who had the inspection of fifty houses, or families.

And in the ancient monasteries, quinquagenarius was a superior who had fifty monks under his guidance.

QUINQUAGESIMA-SUNDAY, Shrove-Sunday. It is thus called, as being about the fiftieth day before Easter. Anciently they used Quinquagesima for Whitunday, and for the fifty days between Easter and Whitunday; but to distinguish this Quinquagesima from that before Easter, it was called the Palchal Quinquagesima.

QUINQUANGLES, See Leaf.

QUINQUANNIUM, QUINQUENNIAL, in the French Calendar, a respite of five years, which insolvent debtors formerly obtained by virtue of the king's letters, to have time for the payment of their debts.

When the thing intended was only to prevent the sale of their effects at an under-value, the term of one year was ordinarily granted, and this was called the benefic of annion.

But when the debtor would avoid the surrendering of his effects, upon proving that he was reduced by poverty, louses, &c. to make use of this expedient, the term of five years was granted, and called the benefit of quinquannion.

QUINQUATORIA, in Antiquity, a name given to the feats of Minerva, otherwise called Panathenaë.

Some think they were termed quinquatira, because they lasted five days; but others, with more reason, think it was because they fell out five days after the idea of the month.

QUINQUE Poutes, the five cinque ports. "Servitium quod barones quinque portuum praescriptum recognofcent facere ad fummonitionem regis per annum, ci costigerit per 15 dies ad cultum eorum proprium; ita quod primus dies computatur a die quo vela navium erec- runt, usque partes ad quas tendere debent, vel ulterius, quod casum exulter ad cultum ejus." Thorn.

QUINQUEFOLIUM, in Botany, Cinquefoil, the old name of the Linnaean genus Potentilla, many, but by no means a majority, of whole species have five leaflets on a stalk. Gartner, who, like many others, was discontented with Potentilla, substituted the word Pentaphyllum. See Pentatilia.

QUINQUEMOPOIX, in Geography, a town of France, in the department of the Lower Seine; seven miles N. of Rouen.

QUINQUENNALIA, in Antiquity, games, or feasts founded at Tyre, celebrated every five years, in honour of the deified emperors.

The quinquennalia began to be expressed on medals about the middle of the third century. F. Pagi produces a medal whereon are engraved those of the emperor Posthumus; they are not found on any medals of his predecessors.

QUINQUENALIS, a magistrature in the colonies, and municipal cities of the Roman Commonwealth; much the same with adile at Rome.

They were not thus called from their continuing in their office five years; but because they were elected every fifth year, to preclude at the census, and to receive the declaration each citizen made of his effects.

QUINQUENNES, in some old Historians, a name given to a certain people of India, among whom the women began to bear children at five years old, and seldom lived more than eight years. Pliny gives us this account; and Solinus, who repeats it from him, increases the miracle by telling us, that
that they were a nation of women who had no men among them.

**QUINQUEPARTITE LEAF, among Botanists. See Leaf.**

**QUINQUEPRIMI, among the Romans, the five principal men in the senate of every municipal town.**

**QUINQUEREMIS, in the Naval Architecture of the Ancients, a name given to a galley which had five rows of oars. They divided their vessels in general into monocrora and polycrotia: the former had only one tier of rowers; the latter had several tiers of them, from two or three, up to twenty, thirty, or even forty; for such a vessel we have an account of in the time of Philopater, which required no less than four thousand men to row it. See POLYCROTA.**

**QUINQUERTIONES, among the Romans, an application given to those who had gained the victory in the quinquertium, or pentathlon.**

**QUINQUERTIUM** was the same with the Grecian pentathlon, comprehending the five exercices of running, leaping, throwing, darting, and wrestling. See PENTATHLON.

**QUINQUE VIR, frequently wrote V. VIR, a Roman magistrate, who had four colleagues joined with him in the same function.**

There were various kinds of officers thus denominated. Pomponius the lawyer mentions quinquervi on this and on that side of the Tiber, established for the administration of justice in the night-time, in lieu of the ordinary magistrates, who were not judged proper to run up and down the streets in the dark.

Rofinus tells us, that they were sometimes the quinquervi who conducted the colonies, and divided the lands allotted to them among the several families.

Sometimes the epulones were five in number; in which case they were called quinquervi. See EPULO.

**QUINQUEVIRI MONETARI, were officers first erected under the confulature of Valerius Poplicola, to moderate the excessive usury, or interest, which creditors or bankers used to exact from the people.**

**QUINQUINA. See Cortex Peruvianus.**

**QUINSEY, sometimes written Quinanje, and Quincy, in Medicine, a corruption of the French word quinquaine, which again is derived from the Greek, cynanche, κυνάγχη, signifying fore-throat, or inflammation and tumour of the internal faucets. The term is applied generally to inflammations of the throat, but more particularly to the acute inflammation of the tonsils. A tonsil, enlarged from inflammation, is also emphatically called a quinsey. See CYNANCHE TONSHILLARIS.**

**QUINSEY, among domestic animals of the live-stock fort, is an affection about the throat and breast, which often attacks them, and which is very obstinate and troublesome. In horses it is usually called anticor.**

**QUINSIEME, or Quinzieme, in our old Law Books. See FIFTY-THIRD.**

**QUINSICAMOND, or Long Pond, in Geography, a lake of Massachusetts, between Worcester and Shrewbury. This is a beautiful lake, in form of a crescent, about five miles long, and from 60 to 100 rods broad. It is intersected with a number of islets, one of which is upwards of 200 acres in extent.**

**QUINSON, a town of France, in the department of the Lower Alps; 25 miles S.S.W. of Digne.**

**QUINT, a sequence of five cards of the same colour. See Sequence.**

**QUINTA, Ital. QUINT, Fr. (See FIFTH and DIAFORETIC.) The chord of the in thorough-bass is resolved two ways: first, by the base rising one note, and the lowest treble note descending; secondly, by the highest note of the chord rising, and the lowest remaining stationary, when the discord is resolved upwards. This is what Rameau calls le double emploi de la diminution.**

**QUINTA Pars, in old madrigals, a 5th vocal part, composed of the refult of the other four.**

**QUINTAN EFFETTO. See QUINTESSENCE.**

**QUINTAIN, Quintana, in Ancient Customs, a poll, or pillar, driven into the ground, with a buckler fixed to it, for the performance of military exercices on horseback, the throwing of darts, breaking of lances, &c.**

Matth. Paris describes the quintain as a kind of mark, formed like a man from the nave upwards, holding a shield in his left hand, and in his right a fword or flick; the whole so fitted as to turn round on its foot, and foars that a cavalier running a-tilt against it with a lance, if he hit it in the breast, it rolled round, and, unless he were very dextrous, struck him with the fword held in the other hand.

In other places, at the top of a poll, was erected a slender beam fitted to turn round a spindle; at one of whose ends was a slope or flat board, and at the other a bag of sand or dirt. The sport was, with a long flaff, or wooden lance, to ride a-tilt at the board, and to be either fo skilful or lucky to escape the blow of the sand-bag.

This some take to be the familiar with the arietum levatio, frequently prohibited in our old fynods and episcopal constitutions.

The custom is still retained in Shropshire, and some other counties, among the nuptial solemnities. He that breaks the most poles against the quintain, has the prize; which was anciently a peacock, but is now a garland.

Some derive the word from an ancient game called quintus; others from a man of the name of Quintus.

The vallus and palus, mentioned in Cesar, are taken, by Vigenere, for a kind of quintain, or wooden man, fixed up as an adversary, or man of fraw, to prove one's dexterity against.

Mention is made of this exercice in the Code, De Aleatoribus, and in the Partitides of Cujas on the fame. Juvenal speaks of women engaging in it:

"Aut quis non vidit vulnera pali? &c."

**QUINTAIN was also a right which the lord had to oblige all the millers, watermen, and other young people unmarried, to come before his castle every three years, and break several lances or poles against a poll, or wooden man, for his diversion.**

**QUINTAL, in Commerce, the weight of a hundred pounds.**

The quintal admits of some difference in different places, according as the pound confuits of more or fewer ounces, and the ounce is lighter or heavier.

Thus, e. g. the Paris quintal, or hundred, in the old system, yields 125 lbs. at Montpelier; and the Montpelier hundred only 8 lbs. 9 oz. 18 gr. French poids de marë, or 88 lbs. avoirdupois nearly. The quintal of Conflantipole is esteemed the heaviest of all those used in the Levant: it contains 44 okes, or 100 rottoni; the oke being 4 yufdromes or cheques, or 400 drachms, and the rotton 176 drachms. The quintal, or kituel of cotton yarn is 45 okes.

The quintal, or cantaro, weighs about 123 lbs. avoirdupois, and the oke als. 13 oz.; the rotton, 19 oz. and the cheque, 1 1/2 oz. avoirdupois. The quintal is equal to 112 lbs. of Amsterdam; 124 lbs. of Venice; and 160 of Leghorn. The quintal of Lisbon contains 4 arrobas, the arroba 32 pounds, the pound, libra, or arrate, 2 marks, or 16 ounces; the ounce, 8 outavas: 13 1/2 quintals make a ton. The
This form was deemed principally useful for travellers, sailors, &c. infinitely as it renders the quintinessence portable; so that the quantity, e. g. of a pin's point, shall be an efficacious medicine.

**QUINTESSENCE** in *Alchemy*, is a mysterious term, signifying the fifth, or last and highest quintessence, or power, of a natural body.

This is supposed to be, as it were, the soul drawn from the gross body and its four elements, by a most perfect distillation; and, by means of which, the thing is said to be spiritualized, i.e., rendered exceedingly pure, spiritual, and, as it were, incorruptible.

The ancients, who allowed nothing to be real but what has a body, would have the soul of man to be a fifth element, a kind of quintinessence without a name, unknown here below, indivisible, immovable, all celestial, and divine. Fenelon.

**QUINTESSENCE of the Elements**, is the hermetical mercury. **QUINTESSENCE of Wine**, a term used by Glauber to express an essential oil of wine, which he directs to be made by a careful distillation; and which he is very fond of, as having a power to mellow, improve, and even to specify the poorer wines into the nature of those from which it was obtained.

This is one of the schemes of Glauber, generally esteemed an impracticable one. Though very plausible in theory; but though in general there is a disagreeable flavour in the quintessence drawn after his method, which is different from the true flavour of the wine, and spoils the liquor it is added to; yet, by proper care, there is a possibility of succeeding so far as to render this extraneous flavour almost imperceptible, and produce an oil that will mend poor wines extremely, and give a truly vinous flavour to such as are in themselves tasteless. But whatever may be done by this method, may also be done with much more certainty, and much less trouble, by the concentration of wines by freezing. This may be easily practiced in the wine countries; and thus means Burgundy, Champagne, and other the most valuable wines, may be reduced into thick extracts and robes, by the means of which wines may be made in England; a very small quantity of these concentrated wines being sufficient to convert the whole of any of the poor ttablets and insipid wines, which are of themselves of little or no value, into the very wine from which the rob was made; and that in such perfection, that the nicest judge cannot find out the difference.

These robes of wine, made and preserved upon the spot, would also be of infinite use in the wine countries, as they might be kept to improve the wines of bad years. Stahl, De Concentr. Vin. Shaw's Chem. Edi.

**QUINT-EXACT**, in old *Low Books*, the last call of the defendant fused to an outlawry. If he appear not to it, the court, by the judgment of the coroners, returned outlawed, if a matter, waived.

**QUINT1, Bay of**, in *Geography*, a bay and harbour in the N.E. part of lake Ontario, at the mouth of the Trent; formed by a large peninsula, consisting of the townships of Ameliaburg, Sophiasburg, and Maryburg, extending cally from an isle, where is a portage at the head, or W. end of the bay, to Point Pleasant, the eastermmost extremity of the peninsula, opposite to Amherst island. The river Trent discharges itself into the head of the bay, wellward of the portage, and supplies it with the waters of the Rice lake. Wellward of the portage in lake Ontario, is the harbour of Prawle Isle de Quinte, now called Newburgh. The fertility of the soil about the bay of Quinte is generally allowed. The land is rich and easily wrought, and produces several crops without manure; 25 bushels of wheat being often
often produced from an acre. The timber, like that of the other parts of the province, consists of oak, elm, hickory, maple, &c. The bay is narrow throughout, and about 50 miles long, through which distance it is navigable for the small vessels that are used on the lakes. It abounds with wild fowl, and various kinds of fish. The river Trent affords a salmon fishery. In passing from the head of the bay of Quinte into lake Ontario, you cross a short portage, in front of the township of Murray, being the isthmus between it and the peninsula of Prince Edward. At the end of the portage, and before you enter lake Ontario, is a small but very beautiful lake, having very good land on its banks. To the northward of this portage it has been proposed to make a canal for connecting the waters of the bay with those of the lake. A little to the westward of the portage and proposed canal, is the harbour of Newcastle, a situation well suited for commerce and protection, and sheltered from all winds. A knoll on the peninsula affords a healthy site for the town.

QUINTILE, Quintii, in Astronomy, an aspect of the planets, when they are seventy-two degrees distant from one another, or a fifth part of the zodiac.

QUINTILIAN, Marcus Fabius, in Biography, a celebrated teacher of eloquence, was born about the year 42 of the Christian era, during the reign of the emperor Claudius. He is supposed to have descended from a family originally Spanish, but that his father, or grandfather, had settled in Rome. The place of his birth is not known, but it seems certain that he was educated in that capital, where he studied rhetoric under Domitius Afer, a celebrated orator. He opened a school at Rome, and was the first who obtained a salary from the state as a public teacher. After he had remained twenty years in this laborious employment, and obtained the applause of the most illustrious Romans, not merely as a preceptor, but as a pleader at the bar, Quintillian retired to enjoy the fruits of his labours and industry. In his retirement he assiduously devoted his time to the study of literature, and wrote a treatise on the "Causes of the Corruption of Eloquence." Some time after, he wrote his "Institutiones Oratoriae," the most perfect and complete sytem of oratory extant. It is, in truth, one of the most valuable remains of antiquity. It was composed for the use of his son, whose early death he had occasion to deplore, and is an institute for the education of an orator, whom he takes up from the cradle, and conducts through all the periods of instruction to the exercise of his proper art. It accordingly contains many excellent precepts with respect to education in general, especially the early parts of it, which are applicable in all times and countries, as being founded on the nature of the mind. The style of Quintilian is said, by critics, to exhibit tokens of the deterioration of the Latin tongue; but, on the other hand, it must be observed, that every deviation from the usage of the Augustan age has been too readily regarded as a depravation. Quintillian was appointed preceptor to the two young princes whom Domitian deified for his successeurs on the throne; but the celebrity which the rhetorician received from the favours and attention of the emperor, and from the successeurs which his writings met with in the world, were embellished by the los of his wife, and of his two sons, one of whom he describes as a prodigy of early excellence. It is said that Quintilian was poor in his retirement, and that his indigence was relieved by the liberality of his pupil, Pliny the younger. He is supposed to have died about the year 95. His "Institutiones" were discovered in the year 1415, in an old tower of a monastery at St. Gall, by Poggio Bracchiolini. The treatise on the "Causes and Corruption of Eloquence" has not come down to us. The name of Quintilian is affixed to certain "Declamations," of which there are 19 of moderate length; but as the style, method, and manner, are totally different from the rules laid down in the "Institutiones," no good judges attribute them to the name of Quintilian. Of the editions of Quintilian none of the most valuable are those of Gofner, 4to. Götting, 1738; of Lug. Batavorum, 8vo. cum notis variarum, 1665; of Gibson, 4to. Oxon. 1693; and that of Rollin, re-published in London in 1792. There is an English translation by Mr. Guthrie.

QUINTILIAN, Quintii, in Ecclesiastical History, a sect of ancient heretics, the same with the Pepuzians; thus called from their prophetess Quintilia.

In this sect, the women were admitted to perform the ecclesiastical and episcopal functions; grounding their practice on that passage of St. Paul to the Galatians, where he says, "That in Christ there is no distinction of males and females." In their assemblies, it was usual to see the virgins enter in white robes, perforating the prophetesses. The Quintilians bore some resemblance to the modern Quakers.

QUINTILIS, in Chronology. See July.

QUINTIN, or Quint, in Commerce. See Quentin.

QUINTIN, in Geography, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of St. Brieuc; nine miles S.W. of St. Brieuc. The place contains 3976, and the canton 12510 inhabitants, on a territory of 147½ kilometres, in eight communes.

QUINTINIE, John de la, in Biography, famous for his skill in horticulture, was born at Poitiers in 1666. He received a learned education, and was brought up to the profession of the law, in which he gained reputation as a pleader at the bar. A passion for agricultural knowledge led him to it, with great attention, all the authors, ancient and modern, upon that topic; and on a visit to Italy as tutor to a youth, he made great additions to his knowledge from actual observation. On his return he devoted himself almost entirely to experiments on the culture of trees and plants, and many discoveries which greatly improved the art of gardening. He was the first person who laid down the principles of the art of pruning fruit-trees. He also remarked that a transplanted tree grew only by the new roots which it threw out, and that the old fibres were useless, and ought to be cut off. It does not appear at what time he began to follow gardening as a profession, but he had certainly acquired a high degree of reputation in it when he was invited to England by Charles II, who offered him a considerable pension to engage him in his service. He twice visited London, and a paper of his was published in the Philosophical Transactios, on the culture of melons. He was made, by Lewis XIV., director-general of the gardens in all the royal palaces. In 1690 he published "Instructions pour les Jardins Fruitiers et Potagers," which obtained a high degree of popularity, was frequently reprinted, and was translated into several modern languages. The last edition was entitled "Parfait Jardinier," in two vols. 4to. The author died at Paris in the year 1700.

QUINTO, in Geography, a town of Spain, in Arragon; 20 miles S.E. of Saragossa.

QUINTUS CALABER, in Biography, a Greek poet, who wrote a supplement to Homer's Iliad, in 14 books, in which relation is given of the Trojan war from the death of Hector to the destruction of Troy. He is supposd, from the style of his work, to have lived in the fifth century, but nothing certain can be collected concerning his person and country. His poem was first made known by
cardinal Benefrion, who discovered it in St. Nicholas' church, near Otranto in Calabria; hence the author was named Quintus Calaber. It was published at Venice by Aldus, but there is no date attached to the title page.

Quintus Curtius. See Curtius.

Quintus Fenumius, in Anatomy, a name given by Fallopian and many others to one of the muscles of the thigh, now called the plos magnus.

Quintus Oculorum, a name given by Vefalius and some others to one of the muscles of the eyes, more expressively called by others obliquus superior oculi, and opifex circumgyrationis oculi.

Quinva, in Botany, a name by which some authors have called the amaranth, or cockcomb.

QuinZano, in Geography, a town of Italy; 13 miles S.W. of Brefcia.

Quinzieme, Fr. in Music, the double octave, above or below any found (see Fifteenth); which is the name of a stop in our organs, equidistant from the diapason.

Quiopela, in Zoology. See Viverra Mungo.

Quipos, in Literary History, a name given to knots on cords of different colours, in Peru, which imperfectly supplied the place of writing. This device was adopted, as it has been said, for rendering calculation more expeditious and accurate. The various colours denoted different objects, and each knot expressed a distinct number. Thus an account was taken, and a kind of register kept of the inhabitants in each province, or of the several productions collected there for public use. But as these knots, however varied or combined, no moral or abstract idea, no operation or quality of the mind could be represented, they contributed little towards preserving the memory of ancient events and institutions. The Mexican paintings and symbols, rude as they were, conveyed more knowledge of remote transactions than the Peruvians could derive from their boasted quipos. If, indeed, the latter had been of more extensive use, and better adapted to supply the place of written records, they perished so generally, together with other monuments of Peruvian ingenuity, in the wreck occasioned by the Spanish conquest, and the civil wars subsequent to it, that no accession of light or knowledge is derived from them. Robertson's Hist. Amer., vol. iii.

Quiqui, in Zoology, a species of Mustela; which see.

Quirazai, or Cura Patina, in Ornithology. See Crax Alector.

Quire of Paper, of the French cabier, the quantity of twenty-four or twenty-five sheets.

Quiricia, a name given by some to the stone called quiris by the generality of writers.

Quiricu, in Geography, a town of France, in the department of the Iere; 12 miles E. of Ballay.

Quirinacium Opium, in the Materia Medica, a name given by some to the gum we know by the name of afe fistida.

Quirinalia, in Antiquity, feasts celebrated, among the Romans, in honour of Romulus, who was called Quirinus. See Quirites.

The Quirinalia, called also flutorum serie, were held on the 13th of the calends of March, i.e. on our 17th of February.

Quirini, Angiolo-Maria, in Biography, a learned cardinal, by descent a Venetian, was born in the year 1680. While young he entered into the order of the Benedictines of Monte Cassino. At Florence he pursued a very extensive course of study under several of the most eminent men in science and literature of that age. Upon his entering a professorship in his convent, he delivered an oration "De Moxice Historie Frantia," which was printed. His studies were interrupted some time, by an imagination that he was afflicted with a stone in his bladder; but the death of his physician, who fell a victim to a false impression respecting his own cafe, freed him from his fancied complaint, and in the year 1710 he set out upon his literary travels. He visited Germany, Holland, England, and France, making in the latter country an abode of more than two years, during the greatest part of which time he resided in the Benedictine abbey of St. Germain des Pres. In the course of his travels he formed an acquaintance with almost all the literary characters in those countries, and visited every object of learned curiosity, at the same time everywhere where existing a general effeminacy of his talents, his industry, and his conduct. Upon his return to Italy he published a Dissertation containing a Plan for a History of Italy;—an Essay on the History of Farfa, in the Duchy of Spoletto;—and an edition of the Oifice for Divine Service according to the Ufage of the ancient Greek Church. He was soon after created bishop of Corfu, by pope Innocent XIII., a dignity which he filled in such a manner as to inflire the Greek separatists with veneration for his person. His residence in Corfu was the cause of his composing a learned Dissertation, entitled "Primordia Corcyre ex antiquissimis Monumentis illustrata," 4to. 1725.

In the year 1727, Benedict XIII. raised Quirini to the cardinalate, after having nominated him to the bishorip of Brefcia. His promotion to that see was followed by some publications relative to the literature of Brefcia. His attachment to the see of Rome was displayed by a life of pope Paul II. printed in 1740, the object of which was to defend the memory of that pontiff against the attacks of Platina. Soon after this he was appointed librarian to the Vatican; in this and other posts he continued to serve the cause of literature. It was through his means that a new edition of the works of St. Ephrem was given in 6 vols. fol. in the Greek, Syriac, and Latin languages. He likewise edited the letters of cardinal Pole, written against the principles of the reformers. This prelate died, greatly regretted, at his episcopal residence, in 1755, at the age of 75. Though a vigorous champion of the pappy, he wrote with a spirit of candour and moderation, which obtained the applause of the Protestants themselves. He was affiliated to several literary societies, among which were the academies of Peterburg, Berlin, and Vienna, and the Institute of Bologna. He enjoyed a large revenue, which he expended with munificence, on objects of charity and public splendour. At Rome he beautified the church of St. Mark, whence he derived his cardinal's title, and he contributed liberally to the fine Catholic church at Berlin. He laid the foundation, by a valuable gift of books, of a public library at Brefcia. His own select and valuable library he presented to the Vatican. His charities were numerous and extensive, and he was indefatigable in performing his pastoral duties, visiting the alpine parts of his diocese in the most inclement seasons. Besides the works already mentioned, he published an account of his own life, and a narrative of his travels.

Quiriquine, in Geography, an island on the coast of Chili, near the entrance into the bay of Conception. 8. lat. 36° 35'.

Quiris, Quirina later, a name given, by the writers of the middle ages, to a stone famous among them for its imaginary virtues, but of which they have left us no description.

Quirister, Chorister, or Charisla, a person appointed
pointed to sing in the quire, or choir, of a cathedral. See Anthem, Chantor, and Choir.

QUIRITES, in Antiquity, an appellation given to the people of Rome, chiefly the common citizens, as distinguished from the senators.

It took its rise from the Curetes, the inhabitants of the Sabine town Cures. On this occasion Romulus, and Tatius king of the Sabines, having united their two people, and their two flutes, into one; upon Romulus’s death and defilement, the Sabines, outdoing the Romans in number, became masters of the councils; and accordingly appointed, that Romulus should be denominated Quirinus, from Cures, a city of the Sabines; or rather from Quirinus, the name of a god worshipped in that city.

From the new Quirinus, all the people came afterwards to be called Quirites; unless we will suppose, that the same authority which denominated Romulus Quirinus, from Cures, did also denominate the people Quirites, immediately from the Curetes.

Some authors derive the word Quirinus from Curis; which, in the Sabine tongue, signified a pike, or halbert. Struvius adds, that Romulus was always painted with a pike in his hand.

Julius Caesar, as Tacitus informs us, (Annal. i. 43.) appealed a sedition by the use of this word Quirites, which opposed to foldiers, expressed contempt, and reduced the offenders to the left honorable condition of mere citizens. The emperor Alexander also applied it to the same purpose. See his biographical article.

QUIRK, in Building, a piece of ground taken out of any regular ground-plat, or floor.

Thus, if the ground-plat were square, or oblong, and a piece be taken out of a corner, to make a court, or yard, &c. the piece is called a quirk.

QUIROGA, in Geography, a town of Spain, in Galicia; 24 miles N.E. of Orense.

QUIROS, CAPE, lies on the E. coast of the island of Espiritu Santo, in the South Pacific ocean. S. lat. 14° 56' 8" E. long. 167° 20'.

QUIRPELE, in Zoology, the name of a small animal, called by some authors the Indian ferret, or viverra Indica, and by others quill. See Viverra Mungo.

Garcias and some others give very remarkable accounts of the enmity this creature has to herpers of all kinds. They tell us, that when this little creature intends an attack upon one of these animals, it first prepares against danger, by gnawing a quantity of the root of the lignum colubrum, or snake wood; and when it has thoroughly impregnated its fælva, it wets with it first its fore-feet, and with them daubs over its head and its whole body; and that thus prepared, it boldly attacks the snake, and never leaves off till it has killed it. Garcia affirms us, that many of the Portugueze have been eye-witnesses of these combats.

It is probable enough, that this creature may attack a snake when thoroughly hungry, knowing its flesh to be good food; but the story of the antidote is to be suspected.

See Ichneumon.

QUIRPN, in Geography, an island in the North Atlantic ocean, near the N. coast of Newfoundland. N. lat. 51° 40'. E. long. 52° 22'.

QUIRSKYCK, a town of Norway; 60 miles N.N.E. of Romdal.

QUIS, in Natural History, a kind of marcarite of iron or copper, from which vitriol is drawn. It is more frequently called pyrites.

QUISBRO, in Geography, a town of Sweden, in Nericia; 12 miles S.W. of Orebro.

QUISCALA, in Ornithology, a species of Gracula; which see.

QUISIBI, in Geography, a town of Arabia, in the province of Oman; 180 miles W. of Julfar.

QUISIL AUREN, a town of Asiatic Turkey, in Carnia; 15 miles W. of Cogni.

QUISONGALA ISLANDS, a cluster of small islands in the Indian sea, near the coast of Africa. S. lat. 10° 40'.

QUISPICANCHE, a jurisdiction in the diocese of Cusco in Peru, beginning at the fourth gates of Quito, and stretching from E. to W. about 20 leagues. The lands of this jurisdiction belong, in general, to the richer inhabitants of Cusco, and produce plenty of wheat, maize, and fruits.

Here are also manufactures of baihe and coarse woollen stuffs. Part of the jurisdiction borders on the forests inhabited by wild Indians, and produces great quantities of cocoa, or cacao, an herb greatly used by the Indians working in the mines, and forming one of the principal branches of its commerce; the town lies 12 miles S. of Cusco.

QUISQUALIS, in Botany, a name combined by Rumphius of quis, who, and quis, what kind or manner, by which he intended to express the singular variableness of the plant, as if nothing could be found like it.—Linne. Gen. 215. Schreb. 295. Willd. Sp. Pl. v. 2. 579. Mart. Mill. Dic. v. 4. Juff. 78. Lamarck Illust. t. 357.

Gen. Ch. Cal. Perianth inferior, tubular, thread-shaped, very long, deciduous, its border in five spreading segments. Cor. Petals five, inserted into the mouth of the tube, sellite, oblong, obtuse, spreading, much larger than the segments of the calyx. Stam. Filaments ten, bristle-shaped, inserted into the tube of the calyx, five of them below the rest; others oblong, in or above the mouth of the tube. Pist. Germe superior, ovate; style thread-shaped, longer than the stigmas; stigma obtuse, dilated. Peric. Drupa dry, with five unequal angles. Seed. Nut elliptic-oblong, pentagonal.

Eff. Ch. Calyx with a thread-shaped tube; five-cleft. Petals five. Drupa superior, with five angles.

1. Q. indica. Linn. Sp. Pl. 556. (Quiqualis.) Rumph. Amb. v. 5. 71. t. 48. Q. pubescens; Burm. Ind. 104. t. 35. f. 2, and Q. gladra; t. 28. f. 2.—Native of Java, and the Molucca isles; naturalized by Rumphius in Amboyana. The fles is shrubby, at first low and stumpy, but subseqently throwing out long trailing or twining shoots, which become as thick as a man’s arm. To this dexterity of habit, and the changeable hue of the flowers, the name alludes. The young branches are clothed with fine soft down. Leaves opposite, occasionally scattered, on shortish downy stalks, ovate, pointed, entire, two or three inches long; their ultimate veins finely reticulated; both surfaces more or less downy, rarely smooth. Flowers in axillary or terminal bracted spikes. Bractæ ovate, downy. Corolla two inches long, downy, white in the morning, turning pale red in the afternoon, rofe-coloured in the evening, and the next morning of a blood red. Fruit as big as one joint of the fingers. Nut edible when quite ripe, having the flavour of a quill. When unripe, Rumphius compares it taste to that of a radish. These nuts are a popular remedy, among the Malays, for worms in children. Two or three of the pungent unripe ones, or five of those that are arrived at maturity, are a dose. Some persons are attacked with a dangerous hiccup from eating two or three of the nuts in question, whilst others find no such effect from a considerable number. The integuments are carefully removed. They probably partake of the p p 2 poisonous
poisonous qualities of the Mezereon tribe; though in a mild degree, as Rumphius speaks of the flavour of several parts of the plant, without mention of any very hurtful properties. Even the kernels of our European Daphne are highly acrimonious.

QUIQUISANA, in Geography, a town of Peru, in the diocese of Cusco; 32 miles S.E. of Cusco.

QUISSAC, a town of France, in the department of the Gard, and chief place of a canton, in the district of Le Vigan, having a mineral spring; 20 miles N. of Montpellier. The place contains 1310, and the canton 3884 inhabitants, on a territory of 1600 kilometres, in 12 communes.

QUISTELLO, a town of Italy, in the department of the Vicenza; 15 miles S.E. of Mantua.

QUISTORP, John, in Biography, a German Lutheran divine and professor, was born at Rostock in the year 1584. He pursued his academical studies at his native city, at Berlin, and at Franckfort on the Oder; and afterwards travelled through Holland, Brabant, and Flanders, in the capacity of governor to the son of a patrician of Louvain. In 1614, his learning and abilities pointed him out as a fit person to fill the divinity chair at Rostock; but before he entered upon the duties of his office, he was created Doctor of divinity. He obtained other preferments in the church, particularly the archdeaconry of St. Mary's at Rostock. In 1645 he was appointed pastor of the same church, and superintendent of the preachers in the district of that city. He had the felicity of rendering important services to the celebrated Hugo Grotius, during his last fatal illness at Rostock. Upon the death of that great man, he wrote a Latin letter to Calovius, containing an account of his sickness and last sentiments, which is inserted in the "Bibliotheca Choitei" of Colomes; and in the "Vindiciae Grotianae," under the title of "Grotii Manes." Quistorp died in 1648, at the age of 64. He was the author of "Annotations in omnes Libros Biblicos," "Commentarius in Epistolam Sanet Philii," and several other works. He left a son of the same name, who was born at Rostock in 1624, and died in 1669. He became pastor, professor of divinity, and rector of the university in that city.

QUISTRUM, in Geography, a town of Sweden, in the province of Väst Gothland; 9 miles N.W. of Uddevalla.

QUITANGONE, a river of Africa, which runs into the Indian sea, 15 miles N. of Mozambique. S. lat. 14° 40' N. long. 30° 30' E.

QUITAPABILLA, a river of America, being a branch of the Wetara, which falls into the Sulquehamah at Middleton.

QUITAFORA, a town of the state of Georgia. N. lat. 33° 25'. W. long. 80° 48'.

QUITCHE, in Agriculture, a name frequently applied, in many districts, to a very troublesome foot of plants of the weed kind; for though it properly belongs to the couch-grasfs plant only, it is much used to signify others of the creeping perennial rooted sort, as the bent, creeping, soft, and tall oat-grasfs, as well as some others, which are only capable of being destroyed by repeated summer ploughings, or forking them out and burning them on the ground. See Couch.

QUITCHE-GRASFS, the common name given in some places to a very troublesome foot of weed, found in many districts, and which requires great exertion to eradicate it out of the land. See Couch.

QUITCHE-Drag, that sort of useful tool of the drag-kind, which is employed in the dragging out and removing this foot of weed from ploughed kinds. It is made in several different methods, according to circumstances; but has molly something of the long triangular form in the beam part, into which the teeth or tines are fixed. These are seldom made so large in this as in the heavy sorts of drags; but they are molly a little hooked, or bent forward, towards the points or lower ends. The frame-part is sometimes fet with two rows of tines, or more.

It is a sort of tool which is frequently made use of for rendering arable ground perfectly clear of root weeds, being had recourse to before the last ploughings. Where the land has been crofs-ploughed, this kind of drag may be employed with great advantage in bringing it into proper order. It has some other names in different counties. See COUCH-Drag, and Drag.

QUITCHE-RAKE, a name given in many districts to the rake employed in collecting the weed called couch, from the surface of ploughed ground, as well as some other sorts in particular cases. The head of this tool, into which the teeth or tines are fastened, is usually about five feet in length; the tines are made in a round form, having a projection of about eighteen inches below the head, each being gradually turned or crooked forward about two inches; the distance from each other also about two inches. There is commonly a small beam made to fall in the middle with two pieces of wood, which come from each corner of the rake-head, into which the tines are fastened by means of a pin that goes through the beam, and keeps the rake-head steady. In working, this implement may be put on the carriage-part of a two-wheeled plough, to be drawn by one horse; a man going behind to occasionally lift up the rake when full, in order to leave the couch and other weeds in rows, for the purpose of burning them. In this manner, a great deal of weeds and trumpery may be collected together in the course of a day. See COUCH-GRASFS RAKE.

QUIT-CLAIM, a release, or quitting one's claim or pretensions to a thing.

QUITerva, in Geography. See SOPALA.

QUITeva, or RIFEA, a town of Africa, in the country of Darah, defended by a castle; 75 miles S.E. of Morocco. N. lat. 28° 6'. W. long. 5° 26'.

QUITO, an extensive province of South America, which was subjected to the Peruvian empire, by Huana Capac about the year 1526, at the time when the Spaniards first visited the coast of Peru. Huana prevailed on his legitimate and eldest son Huncaur to allow one of his natural children, Atahualpa, by the daughter of the last king of Quito, to hold the kingdom as a feud of the empire. Atahualpa, however, rebelled, seized the empire, imprisoned his brother, and soon after put him to a violent death. His prosperity was of short duration; for in the year 1533 he suffered the same fate, by order of Don Francisco Pizarro, who had deputed Sebastian de Benalcazar to conquer the kingdom of Quito. Having by a series of victories made himself master of the kingdom, he proceeded in the year 1534 to rebuild the capital, which had suffered much from internal commotions, and called it "San Francisco de Quito," a name which it still retains, though it was not till seven years after this date that it obtained the title of city. The province, which the Spaniards found annexed to the kingdom of Peru, continued in that state till the year 1718, when it was dismembered from Peru, and attached to the vicerealty of New Granada. At the same time the province of Quito was suppressed, together with that of Panama, in the kingdom of Terra Firme; though the latter continued dependent on the vicerealty of Lima. See NEW GRANADA and PERU. This province is bounded on the north by that of Santa Fe de Bogota, and includes part of the government of Popayan; on the south it is limited by the governments of Peru.
towards the east it extends over the whole government of Maynas, and the river of the Amazon, to the meridian of demarcation, or that which divides the dominions of Spain and Portugal. Its boundary on the west is the sea, from the coast of Machala, in the gulf of Piura, to the coast of the government of Atacames, and the jurisdiction of Barbacoas, in the bay of Gorgona. Its greatest breadth from north to south is about 200 leagues; and its length from east to west, the whole extent from Cape de Santa Elena, in the South sea, to the above-mentioned meridian, which, by the most accurate computation, is 600 leagues. All the parts, however, that can properly be said to be peopled, and actually subject to the Spanish government, are those intercepted by the two Cordilleras of the Andes, which, compared with the whole extent of the country, may be termed a street or lane, extending from the jurisdiction of the town of St. Miguel de Ibarra to that of Loja; the country from hence to the government of Popayan, and also that comprehended between the western Cordillera and the sea. With this limitation, the extent of the jurisdiction from east to west will be 15 leagues, or somewhat more, being the distance intercepted between the two Cordilleras. But to this must be added the countries comprehended in the governments of Jaen de Bracamoros, which borders on the jurisdiction of Loja, and the extremity of the whole province, and situated on the east side of the eastern Cordillera; and to the northward, the government of Quixas, and that of Maynas to the easternd side of it, but separated by large tracts of land inhabited by wild Indians; and on the north side of the province from that of Popayan; though the latter is properly a distinct province from that of Quito. Thus, on the west side of that interval between the two Cordilleras lies the government of Atacames, and the jurisdiction of Guayaquil; on the east side, the three governments above mentioned; and on the north, that of Popayan.

This province, exclusive of these five governments, consists of nine jurisdictions, called in that country provinces, that of Quito being subdivided into as many others as there are governments and jurisdictions. Thefe in the province of Quito, beginning with the most northerly, are the following: viz., the town of San Miguel de Ibarra, the village of Otabalo, the city of Quito, the afliento of Latacunga, the town of Riobamba, the afliento of Chimbo, or Guaranda, the city of Guayaquil, the city of Cuenca, and the city of Loja.

The jurisdiction of Quito, the third of these above enumerated, consists of 25 parishes, besides those in the city, and extends more than five leagues, comprehending lands covered with plantations, producing a variety of plants and fruits, according to the quality, situation, and exposure of the ground. Thofe in the temperate parts yield plentiful harvests of maize; and thofe at the bottoms of deep cavities, being in a hot temperature, are planted with sugar-canes, from which are extracted great quantities of sugar and rum. The plantations near the summits of the mountains, having a variety of temperatures, produce wheat, barley, pot-herbs of all kinds, and potatoes. Above these plantations are fed numerous flocks of sheep, producing wool which affords employment to a great multitude of people. Some farmers breed cows, with the view to the advantage derived from their milk in making cheese and butter. In other farm-houses, various occupations are observed, such as breeding of cattle, agriculture, and manufactures, particularly of cloth, bays, and ferges. The degree of cold and heat in this jurisdiction is subject to sudden variations, according to the situation of different places; but in the fame place vicissitudes seldom occur. The villages in this jurisdiction are constructed with little regularity. They consist principally of a church and parsonage, called the convent, the priests being formerly all religious; the other parts present a number of huts with mud-walls, scattered all over the country, where every one has his appropriate piece of ground, which he tills for his subsistence. A great part, and in some villages the whole, of the inhabitants are Indians, who live there when out of place; though in some parts the inhabitants are Mefilzos, and here and there a Spanish family; but these are extremely poor.
of Bethlehem. Among the courts whose felons are held at Quito, the principal is that of the Royal Audience, established there in 1563; the exchequer or chamber of finances, a treasury for the effects of persons deceased, &c. The corporation consists of a corregidor, two ordinary alcaides chosen annually, and regidores. The cathedral chapter consists of the bishop, dean, archdeacon, chanter, treasurer, a doctor, a penitentiary, a magister, three canons by presentation, four prebends, and two demi-prebends, with the following salaries; that of the bishop 24,000 dollars, the dean 2500, the four succeeding dignities 2000 each, the canons 1500 each, the prebends 600, and the demi-prebends 420. This chapter was created into a cathedral in 1545, and among other festivals celebrated in it, the most magnificent are those of Corpus Christi, and the Conception of our Lady, when all the courts, offices, and persons of eminence assist. In the former there is a singular pomp of the procession of the host, and here are also dances of a peculiar nature, which were performed before their conversion to Christianity. The corporation and cathedral chapter keep, by vow, two annual festivals in honour of two images of the Virgin, which are placed in the villages of Guapulo and Quinchau, belonging to this jurisdiction. These images or statues are brought with great solemnity to Quito, and each festival is succeeded by nine days' devotion, the audience and other courts affiling on the occasion. These festivals are held in commemoration of the affilience vouchsafed by the holy Virgin, at the time of an earthquake and terrible ejection from Pichincha, by which Latacunga, Hambato, and a great part of Riobamba, were utterly destroyed; whereas by the suppos'd interpolation of the Virgin, the city escaped even the slightest damage.

The celebrated city of Quito is said by Alcedo to contain 58,000 persons, some of whom are distinguished by their rank. These are the descendants either of the original conquerors, or of other persons who in succeeding times came over from Spain invested with some lucrative office, and who have preferred the indulgence, both of their decent and wealth, by intermarriages, without mixing with meaner families though famous for their riches. The lower orders of people consist of four classes, Spaniards or whites, Mellizos, Indians or natives, and Negros, with their progeny. The former, according to the statement of Ulloa, compose about a fifth part of the population; the Mellizos, or descendants of Spaniards and Indians, amount to about a third part; the Indians form about another third; and the others, who are about one-sixth, are the Carts. The Spaniards are prevented by their pride from applying to any kind of labour, and therefore many of them are poor and wretched. The Mellizos occupy themselves in arts and trades, but principally in those of the highest repute, such as painting and sculpture, in which they excel. These men of talent, however, are indolent and slothful, so that they loiter about the streets during the whole day. The Indians, who are generally shoemakers, bricklayers, weavers, or engaged in similar occupations, are not more industrious. Persons of fortune among the Spaniards affect great magnificence in their dress, wearing the finest gold and silver tinctures; but that of the middling and lower class is a black cloak, and under it a long coat, reaching down to their knees, with a close sleeve, open at the sides, without folds, and ornamented with rows of buttons. The Mellizos generally wear blue cloth, manufactured in this country. The dress of the Indians consists only of white cotton drawers, made either from the fluffs of the country, or from others brought from Europe, reaching down to the calf of the leg, and edged with lace suitable to the stuff. The use of a shirt is supplied by a black cotton frock, worn by the natives; and over this is a kind of ferge cloak, through which the head paffles, and a hat made by the natives. The men, both Creoles and Spaniards, are well made, of a proper stature, and of a lively agreeable countenance. The Mellizos in general are also well made, often taller than the ordinary size, very robust, and have an agreeable air. The Indians, both men and women, are generally low, but well proportioned and very strong. The Indians have no beard, nor have either males or females any indications of the age of puberty. The youths of family are instructed in philosophy and divinity, and some, with reluctance, proceed to the study of the civil law. The country is observed to abound more in women than men; and it is observed, that nature begins to decay at the age of thirty in the male sex, especially among those who have been tenderly brought up; whereas the females enjoy a more confirmed state of health and vigour. This difference is ascribed partly to the climate and partly to the food, but principally to early intemperance and voluptuousness, and also the want of proper employments. The liquors that are used here are rum and brandy, in which they freely indulge, and also the infusion of the Paraguay herb, which serves for tea. The vices prevalent here are idleness, drunkenness, and gaming. The common people and Indians are much addicted to theft, in which they are very artful and dextrous. In Quito, and in all the towns and villages of its province different dialects are spoken, Spanish being no less common than the Inga.

Quito is so happily situated, that neither the heat nor cold is troublesome; though the extremes of both may be felt in its neighbourhood. An equality of temperature takes place throughout the whole year, the difference between the feasons being scarcely perceptible. The winds are salubrious, and blow continually, but never with any violence. The rain occasionally descends in impetuous torrents. Earthquakes are not uncommon, and when they occur very violent; that of 1775 was very destructive. The great earthquake on the 4th of February 1797, which changed the face of the whole province, and in one instant destroyed thirty-five or forty thousand persons, has so altered the temperature of the air, that the thermometer is now commonly 41° to 54°, and seldom rises to 68° or 70°; whereas Bouguer observed it constantly at 66° or 68°. Since this catastrophe earthquakes are continually recurring; and such shocks, it is probable, that all the higher ground is one vast volcano. Von Humboldt adds, that what are called the mountains of Cotopaxi and Pichincha are but little summits, the craters of which form distinct conduits terminating in the fame cavity. The earthquake of 1797 afforded a melancholy proof of this; for the ground then opened every where, and vomited forth sulphur, water, &c. Notwithstanding the dangers and horrors that suround them, the people of Quito are gay, lively, and variable, and very much addicted to pleasure, luxury, and amusement. Humboldt informs us, that the volcanoes of Quito eject pumice, bafalt, and porphyry flocurated; with enormous quantities of water and liquid clay, which diffuse fertility eight or ten leagues round. The fertility of this country is such, that, as we are informed, a full description of it would appear incredible. The equality of the climate, as well as the fertility of the soil, occasion a regular succession of the productions of the earth; when the fruits have obtained their maturity, and the leaves begin to change their colour, fresh leaves, blossoms, and fruits, are seen in their proper gradations on the same tree. The fame incessant fertility is conspicuous in the corn, reaping and fowing being both carried on at the same time. This remarkable fecundity of the soil is naturally productive of excellent
excellent fruits and corn of every kind, as is evident from the delicacy of the beef, veal, mutton, pork, and poultry of Quito. One of the principal foods used by the inhabitants is cheese, of which it is computed that the quantity annually consumed amounts to between seventy and eighty thousand dollars of the money of that country. The vicinity also affords excellent butter. The manufactures of this province are cottons, some white, called tucuyos, and others striped bays and cloths, which meet with a good market at Lima, for supplying all the inward provinces of Peru; and the returns are made partly in silver, and partly in gold and silver fringes made in that city, wine, brandy, oil, copper, tin, lead, and quicksilver. The products of the earth are chiefly confined within the province; except the wheat, part of which is sent to Guayaquil. But this trade is carried on by Metzizos and poor people. Goods, manufactured by the public, or woen by private Indians, are sent, together with some kinds of provisions, to the jurisdiction of Barbacoas. These provisions are exchanged for gold, found in that country, and which is afterwards sent to Lima, and disposed of at a greater price. Their stuffs find a vent in the governments of Popayan and Santa Fé. The coal of New Spain supplies this province with indigo, of which a great quantity is consumed; blue being universally the colour which these people affect in their apparel. They also import, by way of Guayaquil, iron and steel, both from Europe and the coast of Guatemala. S. lat. 0° 13' 27". W. long. 78° 10' 15". Ulloa's Voyage, vol. i.

QUIT-RENT, q. d. quiet rent, a certain small rent, payable yearly, by the tenants of mofl manors, in token of subjection; upon the payment of which, they are quiet, and free. It includes both rents of alhe and chief rents. These rents differ very greatly in different manors, being in some a mere trifle, while in others they are very heavy and oppressive to the tenants. This part of the feudal system is now considerably on the decline.

In some ancient records it is written white rent, because paid in silver, to distinguish it from rent-corn, rent-pepper, &c.

QUITTA, in Geography, a town of Africa, on the Slave coast. N. lat. 6°. E. long. 0° 8'.

QUITTANCE. See Acquittance.

QUITTER, or Quitior, in horfes, is an ulcer formed between the hair and hoof, usually on the inside quarter of a horse's foot; it often arises from treads and bruises, sometimes from gravel, which, by working its way upwards, lodges about the coronary; if it is only superficial, it may be cured with cleansingdressings, bathing the coronary every day with spirits of wine, and dressing the sole with lime-water, or a detergent application, such as red precipitate. But where the matter forms itself a lodgment under the hoof, there is then no way to come at the ulcer but by taking off part of the hoof; and if this be done well, the cure may be effected without danger.

When the matter happens to be lodged near the quarter, the farrier is sometimes obliged to take off the quarter of the hoof, and the cure is then for the most part palliative; for when the quarter grows up, it leaves a pretty large seam, which weakens the foot; this is what is called a false quarter, and a horse with this defect seldom gets quite found.

If the matter, by its confinement, has injured or destroyed the coffin-bone, which is of so soft and spongy a nature that it soon becomes curios, it will be necessary to enlarge the opening, cut away the spongy flesh, and apply the actual cautery, or hot iron, pointed pyramiddally, dressing the bone with doffs of lint dipped in tincture of myrrh, and the wound with the green or precipitate ointment. When the fore is not enlarged by the knife, which is the best and least painful method, sublimation is generally applied; or blue vitriol powdered, and embued with a few drops of oil, is also used for this purpose, and is said to act as effectually, and with less pain to the animal.

In the time of the action of these caustic remedies, the foot should be kept in a poultice. And where sinuses form they should be laid open by a knife, and be afterwards stimulated by the application of some detergent remedy. The following has been advised by a late writer: Take of corrosive sublimated, red precipitate in fine powder, of each equal parts; honey sufficient to form a paste. The wound is advised to be afterwards dressed with common digestive ointment, prefure being given by means of a bandage. It is sometimes written quitter.

QUITTER-BONE, another term applied to the same difeafe by farriers and perffons engaged in husbandry.

QUITY, in Botany, a Brazilian name used by some authors for the sapindus, or soap-berry tree of the West Indies.

QUIVER, seemingly corrupted from the Fr. couvrir, to cover, a cafe or sheath for arrows.

QUIVISA, in Geography, a town of Hindoostan, in Bahar; 25 miles S.W. of Bettyah.

QUIVISIA, in Botany, from the vulgar name of this tree or shrub in the isles of Bourbon and the Mauritius, bois de guiui. Juff. Gen. 264. Cavan. Diff. 367. (See Gil-lerbitia.) One cannot but wonder how a writer of Ju"fieuc's learning could, for a moment, tolerate so faulty a name; especially as his authority leads needfels persons into the adoption of such, for want of reading his preface; and, in a note to p. 24, he declares these rude and barbarous names to be merely borrowed for a time, till the genera to which they belong are better determined.

QUIXOS, in Geography, a jurisdiction of South America, attached to the province of Quito, on the east side of the Cordillera of the Andes. Quixos on the north side borders on the jurisdiction of Popayan; reaching eastward to the river Aquiraco, and towards the west separated from the jurisdictions of Quito, Latacunga, and the town of San Miguel de Ibarra, by the Cordilleras of Cotopaxi and Cayambe. This country was first discovered in 1536, by Gonzalo de Pineda, one of the officers sent from Popayan by Sebastian de Belalcazar (or Benalcazar;) to trace the course of the river Magdalena; and in consequence of his report, Gonzalo Pizarro, in 1539, reconnoitred its whole extent, and established settlements in the country. But upon the failure of his expedition, the conquest of this country was suspended till the year 1549, when the marquis de Canete, viceroy of Peru, gave a commision to Gil Remirez Davalos, a man of unadauated courage, for reducing the Indians, and making settlements in the country. This object he accomplished, and founded the town of Baêza, the capital of the government, in the year 1559; and this was soon followed by other towns and villages, the principal of which are Archidona and Avila. The temperature of this country is hot and moist, the rains being almost continual. It is covered with thick woods, some trees being of a prodigious magnitude. In the S.W. part of the jurisdiction of Quixos is the canela or cinnamon tree, which led Gonzalo de Pineda to call the country Canelos, a name which it still retains. The other products of Quixos are the fame with those in all the other lands under the same climate as this government. Adjoining to this is the district of Macas and Maynas, and the Quixos, in Ancient Geography, a town of Africa, in Mauritanian Casariensis. This was a fortress, according to Pomponius Mela and Pliny. Antonine makes it a municipium, and places it between Porfus Magnus and Arfearia.

QUIZAMA,
QUO

QUIZAMA, in Geography, a province of Africa, in the southern part of Angola; the country is extensive, mountainous, and badly cultivated; but it produces abundance of honey, wax, and salt. The inhabitants are warlike, and have not submitted to the Portuguese.

QUIZIBA, a small island in the Indian sea, near the coast of Africa. S. lat. 12° 30'.

QUIZIMALUGO, a river of Africa, which discharges itself into the Indian sea, S. lat. 8° 30'.

QUIZINAJ or Teusin, a chain of mountains in Fez, 90 miles in extent.

QUIZUMGO, a river of Africa, which runs into the straits of Mozambique, S. lat. 17° 30'.

QUO JURE, in Last, a writ that lies for him who has land, wherein another challengeth common of pasture time out of mind: its design is to compel the party to fly by what right or title he challengeth it. This is now out of use, as, on the claimant's putting his cattle in, the owner may bring trespass, when the claimant must plead and prove his title.

Quo Minus is also a writ which lies for the king's farmer or debtor in the court of exchequer, against him to whom he selleth any thing by way of bargain, touching his farm, or against whom he hath any cause of personal action; because by the vendee's retaining any due from him, the farmer is lesse able to pay the king's rent. This was formerly allowed only to such persons as were tenants or debtors to the king: at this day the practice is become general for the plaintiff to furnish, that, for the wrong which the defendant doth him, he is lesse able to satisfy his debt to his majesty; which furniss gives jurisdiction to the court of exchequer to hear and determine the cause. Finch. 66. 66. New N. B. 148.

Quo minus is also a writ that lies for him who has a grant of housebote and haybote in another man's woods, against the grantor making such waife, as that the grantee cannot enjoy his grant.

Quo Warranto, a writ that lies against any person or corporation (which feo) who usurps any franchise, or liberty, against the king; as to have waife, lray, fair, market, court baron, leet, or such like, without good title; to inquire by what authority he supports his claim, in order to determine the right. Finch. L. 322. 2 Inst. 282.

It also lies for mis-use or non-use of privileges granted; and even, according to Bracton, against him that intruded himself as heir into land. See Intrusion.

This writ was originally returnable before the king's justices at Westminster; but afterwards only before the justices in eyre, by virtue of the statutes of " quo warranto," 6 Edw. 1. c. 1. and 18 Edw. 1. b. 2. (2 Inst. 498. Ralf. Entr. 540.) but since those statutes have given place to the king's temporary commissioners of affize, the judges on the several circuits, this branch of the statutes hath lost its effect: and writs of "quo warranto" (if brought at all) must now be prosecuted and determined before the king's justices at Westminster. And in case of judgment for the defendant, he shall have an allowance of his franchise; but in case of judgment for the king, for that the party is entitled to no such franchise, or hath diffused or abused it, the franchise is either forfeited into the king's hands, to be granted out again to whomever he shall please; or, if it be not such a franchise as may subsist in the hands of the crown, there is merely judgment of "ouster," to turn out the party who usurped it. Cro. Jac. 259. 1 Show. 280.

The judgment on a writ of quo warranto (being in the nature of a writ of right) is final and conclusive even against the crown. (1 Sidd. 86. 2 Show. 47. 12 Mod. 225.) This circumstance, together with the length of its process, probablyoccasioned that difuse into which it is now fallen, and introduced a more modern method of prosecution, by information filed in the court of king's bench by the attorney general, in the nature of a writ of "quo warranto," in which the process is speedier, and the judgment not quite so decisive. This is properly a criminal method of prosecution, as well to punish the usurper by a fine for the usurration of the franchise, as to oult him, or feize it for the crown; but hath long been applied to the mere purposes of trying the actual right, feizing the franchise, or outling the wrongful possessor; the fine being nominal only. Blackits. Com. b. iii. See Information.

Quod hoc, a term often used in law reports to signify, "as to the thing named" the law is fo, &c.

Quocolos, the name of a stone found in Tuscany, as hard as a flint, somewhat transparent, and, in some measure, resembling marble. In the fire it loses its transparency, and becomes lefs ponderous, and white; and a strong fire readily converts it into glass. It has no medicinal virtues, but is used at some glass-houses.

Quod, Cape, or Quada, a cape on the coast of Patagonia, in the straits of Magellan. S. lat. 53° 33'. W. long. 74° 6'.

Quod clerici beneficiati de cancellaria, in Law, a writ to exempt a clerk of the chancery from the contribution towards the proctors of the clergy in parliament. Rep. Orig. 261.

Quod clerici non elegantur in officio balliari, &c. is a writ that lies for a clerk, who, by reason of some land he hath, is made, or like to be made, a bailiff, beadle, reeve, or such like officer.

Quod cum, that whereas, being by way of recital, and not positively, is not good in indictments. 3 Salk. 188. See Indictment.

Quod ei defercreat, a writ for tenant in tail, tenant in dower, by the courteys, or for term of life, having left their lands by default, against him that recovers, or his heir. Rep. Orig. 171. Stat. Welfm. 2. cap. 4.

This, though not strictly a writ of right, so far partakes of the nature of one, as that it will restore the right to him who has been thus unwarily deforced by his own default. (F.N.B. 155.) But in case the recovery were not had by his own default, and upon defence in the inferior process without action, this ill remains final with regard to those particular elates, as at common law; and hence it is, that a common recovery (on a writ of entry in the poyl) had, not by default of the tenant himself, but (after his defence made, and voucher of a third person to warranty) by default of such voucher, is now the usual bar to cut off an elate-tail.

This writ may be brought against a stranger to the recovery; as if a man recover by default, and maketh a feoffment, this writ may be had against the feoffee.

Quod medium. See Medium.

Quod permetat, in Law, a writ that lies where a man is deforced of his common of pasture, and the defierors aliens or dies seized, and his heir enters; then if the defierors die, his heir shall have this writ. See Disturbance of Common.

Quod permetat proferenir. See Affirm of Nusance.

Quod perpensa nec prelaturis, &c. a writ that lies for spiritual persons, when distrained in their spiritual possessions, for the payment of a fifteenth, with the rest of the parih. F.N.B. 176.

Quodlibetical Question, Quello quodlibetica, a college term for a thesis, or problem, anciently proposed to be debated in the schools, out of curiosity and entertainment, rather than for the settling of any useful point. 6
QUO

The term is formed from the Latin quadrilater, any thing, what you please: and so well satisfied were the public of the impertinences of these questions, that the term quadrilater has been since retained, to signify any little ridiculous quibble.

QUOTA, in Geography, a country of Africa, situated above 100 miles from the coast of the Atlantic, between the 8th and 16th degrees of W. longitude, and between the 17th and 9th degrees of N. latitude.

QUOTIF, in Ship-Building, a piece of oak thickslant on the deck, to which the deck water-way on each side is butted, otherwise the butt would come in the middle, and could not be caulked.

QUOIL, QUOIL, or COIL, in the Sea Language. A cable is said to be quoted, when it is laid round in a ring, one turn over another, on the deck of a ship.

The middle of such ring, or quil, is a good place to lay shot in: they are more safe there than in lockers along the side, where the enemy's shot may fall into them.

QUOL, Weather. See Weather Quoil.

QUOIN, or COIN, formed from the French coin, of the Latin cuneus, wedge, aboard a ship, is a wedge fastened on the deck, close to the breech of the carriage of a gun, to keep it firm up to the ship's side, and prevent its rolling; and also to raile or depres it.

QUOINS, Cantie, are short three-legged ouins, put between cales to keep them steady. See Coix.

QUOINS, in Architecture, denote the corners of brick or stone walls.

The word is particularly used for the stones in the corners of brick buildings. When these stand out beyond the brick-work (their edges being chamfered off) they are called rustic quoins.

QUOIN, in Geography, a small island in the Indian sea, near the W. coast of Madagascar. S. lat. 14°. E. long. 48° 14'. Also, an island in the East Indian sea, N. of the Nicobar islands. N. lat. 9° 56'. E. long. 93° 20'.

QUOITS, a kind of exercise or game, known among the ancients under the name of the difins. See Disc.

QUOLL, in Zoology, a name given by the natives of New Holland to an animal resembling a pole-cat, with a brown back, spotted with white, and the belly of a pure white, in which it differs from others of these fied animals.

QUONDANGA, in Geography, a town of the Burman empire; 32 miles N. of Prome.

QUORUM, a term frequently mentioned in our statutes, and often used in commissions, both of peace, and others. A justice of the quorum is thus called from the words in the commissio, Quorum C. D. or A. B. aliquem vestrum unum effe volumus.

For an example: where a commissio is directed to seven persons, or to any three of them, of which A. B. and C. D. are to be two; there A. B. and C. D. are said to be of the quorum, because the rest cannot proceed without them.

So a justice of the peace and quorum is one without whom the rest of the justices, in some cafes, cannot proceed. See Justices of the Peace.

Quorum Nomina. In the reign of king Henry VI. the king's colonists, and other accomptants, were much perplexed in pasing their accounts, by new extorted fees, and forced to procure a then late-invented writ of quorum nomina, for the allowance and suiting out their quietus, without the allowance of the king.

QUOTA, in Law, a tax to be levied in an equal manner.

Vol. XXIX.
the points placed under them, but according to others substituted in their stead; as is done by St. Peter, Acts iii. 23, by Stephen, Acts, vii. 43, and by Paul, 1 Cor. xv. 54., 2 Cor. viii. 15, &c. The second is by changing the letters; as is done by Paul, Rom. ix. 33, 1 Cor. xi. 6 Heb. viii. 9, and x. 5, and by Stephen, Acts, vii. 43. The third is by changing both letters and points; as is done by Paul, Acts, xiii. 41, and 2 Cor. viii. 15. The fourth is by adding some letters and taking away others. The fifth is by transposing words and letters. The sixth is by dividing one word into two. The seventh, adding other words to make the sense more clear. The eighth, changing the order of the words. The ninth, changing the order of the words and adding other words. Both of which are done by the apostles. And lastly, changing the order of words, adding words, and retaining words; which is a method often used by St. Paul.

Other authors, as bishop Kidder, M. le Clerc, Mr. Sykes, &c. solve the difficulty another way. That usual form of quotation among the evangelists, "That it might be fulfilled which was spoken by the prophets," according to these authors, means no more than an accommodation of the prophet's words to the case in hand.

The word προηγομένου, fulfilled, does not necessarily determine us to such a sense, as if the evangelists designed to speak of a prediction of future events accomplished; but may barely express an accommodation of borrowed words. In effect, says bishop Kidder, a scripture may be said to be fulfilled in two ways: properly, as when that which was foretold comes to pass; and improperly, by way of accommodation, as when an event happens to any place or person like to what fell out some time before. And thus it is that St. Matthew says, on occasion of the murder of the innocents, that "then was fulfilled what was spoken by the prophet Jeremiah, In Rama was a voice heard," &c.

This interpretation is confirmed by M. le Clerc, who observes that the Jews, in their language, used to say, that a passage of scripture was fulfilled, as often as any thing happened to which it might be applied; so that the evangelist Matthew, who was a Hebrew, and wrote, as is commonly supposed, in that language, intended no more in the passage just cited, but that a thing happened, to which one might apply what Jeremiah had formerly said on another occasion.

Accordingly, says Mr. Sykes, the evangelists, in citing that passage of Isaiah, Behold a virgin shall be with child, &c. only use it as words of that prophet remarkably agreeing to the miraculous birth of Jesus, and not as a prophecy of his birth.

It may be added that this way of speaking was not unknown among the heathen writers. Thus in Zélan, Diogenes Laërtius used continually to say of himself, that he fulfilled and underwent all the curses of tragedy.

The difficulty stated in this article has been already the subject of discussion under the terms Accommodation and Priority. Whilst it is allowed, that new; passages in the New Testament, and also in the writers to the Christian fathers, are very different from the correspondent passages as they now stand in the Hebrew text; and that some words are introduced as quotations which are no where to be found; those who urge the objection should be disposed to pay due attention to the various modes of replying to it, which biblical critics have proposed. Some have supposed, with Whitson, that those early Christian writers quoted from the LXX.; others have alleged that they sometimes quoted from their memory; and this, it is said, is the more probable, because the same passage is quoted in some cases by different authors in very different words, even where the sense agrees. It is moreover alleged, that the sense of the passages supposed to be lost is still to be found in the Old Testament, though the words be not; such especially are Matt. ii. 16, and John, vii. 38. But if it were granted, that some of the verses originally belonging to the Old Testament are lost, or materially corrupted, no objection could be justly alleged against the authority and divine authority of the sacred writings in general. As for the quotations that occur in the New Testament, the most probable opinion is, that some of them are made from the Greek version and some from the Hebrew text. To those who affirm, that though such quotations are made from the Greek version, where that differs from the Hebrew, yet both the text and the version are in such places always the same in sense, we reply with Dr. Kennicott, that this is not the case: and he thinks, that the only way of doing justice to our Saviour and his apostles in their references to the Old Testament, is to say, that for whatever purport such quotations were made (whether by way of express prophecy, or only of allusion and accommodation) they were always conformant to the true sense of the Hebrew text. If the former be regarded as possible, to determine, how any speaker or writer can quote juxta fuff used, &c. from Mofes or from Isaiah, when the words quoted are not the words of Mofes or Isaiah, and do not express even the sense of Mofes or Isaiah; but are only taken from some version, which (upon the present supposition) was no version at all in these infallences, because it did not agree here in sense with its original. The foundation of this mistake, as this learned writer adds, is the notion that has prevailed of the integrity of the modern Hebrew text; for the writers who have held this to be perfect, have never been able and never will be able to vindicate the prophetical quotations. Passages quoted from the several Jewish writers by inspired men must (he thinks) have been quoted agreeably to the sense of the Hebrew text; but such quotations do not agree in sense with the printed Hebrew text. Therefore some alterations have happened, either in the Greek text of the New Testament, or the Hebrew text of the Old. Collins says that the Hebrew text has been delivered down perfect; and therefore that the quotations are either forged or falsified in the New Testament. To this it is replied, that as it appears from a collation of the Greek MSS. of the New Testament, that the words of the quotations are not corrupted in the Greek text, so it appears from a collation of the Hebrew MSS. that the words have been corrupted in the Hebrew. And this is an answer which should appertain itself to all Christians. See Kennicott's State of the Hebrew Text, vol. ii. p. 345—347. &c.

Upon the whole we observe, that the writers of the New Testament did not make it a constant rule to quote from the Greek version, because there are many places where their quotations differ from that version, and agree with the Hebrew. And as the quotations now agree with the Hebrew, frequently in the express words, generally in the sense; so it is not improbable, that they always agreed at first, and that where the Hebrew was expressed properly in the Greek version, they used the words of that version; and where the version was not proper, they translated for themselves.

With regard to Matt. ii. 16, the first of the passages above cited, Dr. Doddridge (Fam. Expof. in loc.) observes, that Nazareth was a little city on the confines of Zabulon and Naphar; so contemptible among the Jews, that it was a proverb among them, No good thing can be expected from thence. Thus was fulfilled what was spoken in effect by many of the prophets, "he shall be called a Nazarene;" i.e. he shall
QUO

shall appear in mean and dispicable circumstances, and be
accepted as the mark of public contempt and reproach. If this
sentence be not approved, Dr. Doddridge professes to acquiesce
in Chryfotom's opinion, that the passage referred to is lost,
avouching his dissatisfaction with other interpretations of
this passage. The second passage, viz. John, vii. 38, our
learned expofitor thus explains, "He that believeth in
me, as the scripture hath said, out of his belly shall flow
rivers of living water, i.e. as the scripture has in many
places said and promised, he shall receive those supplies in
too great an abundance, that he shall not only be refreshed
himself, but out of his belly, or from within him shall flow
vital streams, and as it were rivers of living water for the
refreshment and comfort of others." Chryfotom, and after
him many other eminent writers, Callistus, Zegerus, and
I. Capellus, refer the words "as the scripture hath said,"
to the former clause, and understand them, as if our Lord
had said, "He that believeth in me," which the scripture
requires, and thus they avoid the difficulty, which arises
from our not finding the following words in scripture. But
Grotius, with whom Dr. Doddridge agrees, supposes, that
here is a general reference to the several prophecies which
refer to the effusion of the spirit by the Messiah, under the
numbness of pouring out water. See Isaiah, lii. 15, xlv. 3.
liv. 11. Joel, ii. 28.

QUOTIDIAN, in Medicine, signifying literally daily,
is applied to all intermittents diseases, which return once in
twenty-four hours. As the most remarkable of these is the
ague, or intermittent fever of marblecountries; so the term
quotidiano signifies emphatically a quotidian age. The pa-
atory in the morning. See Ague.

QUOTIDIAN, Double, returns twice in twenty-four hours.
QUOTIENT, QUOTIONS, formed from the Latin quoties,
q.d. how often is such a number contained in such another, in
Arithmetick, the number resulting from the division of a greater
number by a smaller; and which shews how often the smaller
is contained in the greater; or how oft the divisor is contained
in the dividend.

In division, as the divisor is to the dividend, so is unity
in the quotient. Thus the quotient of 12 divided by 3 is 4;
which is thus difpofed, 12 (4 quotient.

VOUVEDO, in Geography, a town of Ilitria; six miles
E. of Capo d'Ilitria.

QUOUSQUE. Execution with a Quousque. See Ex-
ecution.

QUOYI. See Quoll.

R.

A liquid confonant, and the seventeenth letter of the
alphabet.

The grammarians hold it a semi-vowel; especially in the
Greek, where, in common with the other vowels, it admits
an aspirate, &c. though whether the aspirate should be
found before or after it, is some doubt. We find influences
of each.

Thus in our Latin, rhaude; and in our the Aetolians
wrote ῥῆδαι; and in English words derived from the Greek
it is followed by an h, as rhaphody. The ancient Goths,
and Teutones, Littleton observes, always prefixed b to r.
See H.

The sound is formed by a guttural extraction of the breath,
vibrated through the mouth, with a fort of quivering motion
of the tongue drawn from the teeth, with the tip a little
elevated towards the palate.

In some words, as Rome, rape, and river, it has a rough
sound; in others, as bard, card, regard, its sound is smooth.
R at the end of many words is pronounced like a mute or,
as in theatre, sipalche, andまして. Rh is used in words
derived from the Greek, as myrrh, rheum, and rhyme.

The Hebrews allow the r, or r, the privilege of a guttural;
that is, they never double it, which yet is done by the
Arabs, Greeks, and Latins, &c.

Periplus calls the r, litera canina, because the dogs feem to
pronounce it in snarling; yet it should feem to have had a
fother found among the Romans than among us, by its being
frequently interpofted to prevent the clafhing of vowels; as
in rarus, æquus, nurus from r, tures from pars, mus murs
from μῦς; and this softness was fuch as frequently oc-
casioned its being dropt as uselefs in writing. Thus for
Hetrifu they frequently wrote Thufi, and even Tufi; and
for fiafu, rufus, proful; fiafu, rufus, proful.

In effect, there was that agreement between the found of
the s and r, that as the Romans avoided the doubling of
their confonants, it was no wonder they here dropped the
r in fuch words; the s supplying the place of both. Hence
too it came to paft, that what they at firft pronounced sfa,
aefia, caefia, was afterwards ara, area, cæfia; and thofe
tierk named Pufi and Valsi, were afterwards called Furii
and Valerii. Cicero tells us, the Papirii were firft called
Paphii; and even fixes the time when the change was made,
ann. in the year of Rome 345. Festus adds, that olia, pig-
nora, plurina, were ancienly written olfa, pingafa, plafa.
From the fame oofines of the found of the r, it came to
be used indifferently with the b, in many words; e.g. Lati-
arius and Latialis, Pallia and Parilia, &c.

Though the r more frequently degenerated into l; thus
remures became changed into lemures; interlógo, into
intellógo, and pollices; frater into fratellías, &c.; and the fame
is sometimes done between n and r, as ar ens, and an ens, &c.

In the notes of the ancients, R. or RO. signified Roma;
R. C. Romana civitas; R. G. C. regendor causa; R. F.
E. D. rēctō sactum et diārum; R. G. F. regis filius; R. P.
res publica, or Romani principe; and R. R. R. F. F. res
Romana rust ferro, fænum, flamma. R was ancienly a numeral letter, signifying 80; accord-
ing to the verie,

"Oecoginta datib tibi R, figius numerabit."
When a dash was added at top, as  $\bar{R}$, it signifies eighty thousand.
The Greek $\tilde{r}$, with a small mark over it, signifies a hundred; with the same mark under it, it denoted $1000 \times 100$; thus $\tilde{r}$ signifies $100,000$.

In the Hebrew numeration, $\gamma$ denoted 200; and with two horizontal points over it, $1000 \times 200$; thus $\gamma = 200,000$.

R on the French coins, denotes their being struck at Orleans.
$R$, or $\mathbf{R}$, in Medicinal Prescriptions, stands for recipes taken.
\textit{RAA}, in Geography, a town of Norway, 10 miles N.E. of Frederikshald.

**RAAB, Gym, or Julavriti, a town and fortress of Hungary, situated in a pleasant level country, at the confluence of the Danube, the Raab, and Rabnitz, which surround it. Its houses are constructed of stone, and its streets are large and straight. It is the seat of a bishop. Its fortifications consist of seven bastions, and it has always a strong garrison, provided with military stores. The fortifications of the city and castle are chiefly the works of the emperors Ferdinand I. and Maximilian II. In this place are seen some Roman antiquities; 56 miles S.E. of Vienna. N. lat. $47^\circ 42'$ E. long. $18^\circ 45'$.

**RAAB, a river of Stiria, which rises near mount Rettilein, and runs into the Danube, near Raab in Hungary.

**RAAF, or \textit{RAF}, Anthony, in Biography, the most exquisite and celebrated tenor singer of the last century, was born at Bonn in 1710. He was a scholar of Bernacchi, and equally admired for his taste, expression, and style of singing, by the Italians and Germans. In 1720 his voice was fitted from a high treble to a sweet and firm tenor, sufficiently for him to perform a capital part in an opera at Naples. After singing in all the great cities of Italy, he returned to Germany, where he was courted and cared for by all the princes of the empire. He was knighted by the Elector of Bavaria, and appointed his chamber musician. In 1731 he performed again at Naples in Metastasio's "Attilio Rigido," with the Mingotti, and in the letters of Metastasio of that period, we have the poet's opinion of his performance. (Mem. of the Life and Writings of Metastasio, vol. i. p. 403.) He performed in an opera composed by Christian Bach at Manheim in 1770, when the celebrated air "Non fo dono d'ève" was in its part, and which was afterwards sung on our opera stage with such effect by Corradi. Raff was at Paris more than once; for in 1780, his 70th year, Labore speaks of him with great respect. "This celebrated tenor has acquired great reputation, and, though at present d'un certain age, he obliges us still to admire his taste, and regret all that he has lost." According to Gerber, Musical Lexicon, vol. ii. he sung at Manheim in 1783, and was living in 1792.

**RAAGOE, in Geography, a small island of Denmark, near the N. coast of the island of Lolland. N. lat. $54^\circ 58'$. E. long. $11^\circ 10'$. **

**RAAJAGUR, a town of Hindoostan, in the country of Malwa, near the river Nenmoudge; 74 miles N.E. of Ougcine. N. lat. $24^\circ 21'$. E. long. $76^\circ 56'$. **

**RAALBRANN, a town of Autfria; seven miles S.E. of Meiffau. **

**RAAN, a town of Autfria; four miles E.S.E. of Hooren. **

**RAASAY, an island of the Hebrides, or Western Islands, Scotland, is situated between the main land and the Ille of Skylo; and is included within the parifh of Portree and shire of Inverness. It is about fifteen miles in length, and from two to five in breadth. On all sides the coast rises to a great height above the level of the sea; and on the east side its aspect is peculiarly bold, and almost perpendicular. The interior is throughout its whole extent mountainous; and hence is better adapted for pasturage than for tillage, but there are nevertheless several spots of very fertile and well cultivated land. The supply of free-flone is almost inexhaustible, and there is likewise plenty of lime-flone. Formerly there were in Raafay several ancient chapels, but these are now ruined and only used as places of burial. Here are likewise remains of two forts, the highest of which was situated at the southern extremity of the island, and is called Dunn-Cann, as tradition records, from Came, cousin to one of the ancient kings of Denmark. The other fort, called Caille-Broichin, is a well-known landmark among sailors. The rock on which it is situated is nearly round, covering an area of little more than seventy feet square; is forty feet high, except at the spot where the floor leads up to it; and is thirty feet above the level of the sea at its base. The castle is built of stone and lime, and seems to have been no less strongly fortified by art than by nature. It was anciently the chief seat of the lords of Raafay. Now, however, the family residence is at Clachan, or Kirk-town, near the opposite extremity of the island. One of the old Highland alliances has continued for more than two hundred years, and is still subsisting between MacLeod of Raafay, and Maconald of Skye, in consequence of which the survivor always inherits the arms of the deceased; a natural memorial of military friendship. At the death of the late Sir James Macconald, his sword was delivered to James Macleod, esq. the present laird of Raafay. Dr. Johnfon, in his Tour to the Hebrides, speaks in warm terms of the elegance and hospitality with which he was entertained by this truly respectable family. Carlile's Topographical Dictionary of Scotland, 2 vols. 4to. 1813. Pennant's Tour through Scotland, vol. ii.

**RAASS, a town of the duchy of Stiria; five miles W. of Marburg. **

**RAASTORF, a town of Austria; four miles N. of Entzertofen. **

**RAAT, a town of Hindoostan, in the country of Agra; 128 miles S.S.E. of Agra. N. lat. $25^\circ 37'$. E. long. $79^\circ 58'$. **

**RABAICAL, a town of Portugal, in the province of Beira; 12 miles S. of Coimbra. **

**RABANUS, philus Magnentius, in Biography, a celebrated German prelate in the ninth century, was born at Fulida in the year 785. He was educated partly at Fulida, and partly at Tours, under the famous Alcuin. In the latter situation he distinguished himself by an unexampled application to his studies, and his almost unequalled proficiency in all the learning of the times, both profane and sacred. Not long before the death of Alcuin he returned to Fulida, and embraced the religious profession in its abbey. In the year 810 he was placed at the head of a school belonging to the abbot Ratgarius, and the fame of his superior learning soon raised the seminary into great reputation, and filled it with pupils, many of whom were afterwards promoted to the highest ecclesiastical dignities, and proved the brightest ornaments of the age. In 815 he was ordained priest, and in 822 he was elected abbot of Fulida. About 830 he was, by his prudence and good conduct, the means of effecting a reconciliation between the emperor Lewis le Debonnaire and his foes. Shortly after this, Erbo, archbishop of Rheims, who had been condemned for high treason, was committed to his custody. In 838, at the request of
of count Erldrid, he sent a colony of monks from Fulda, to occupy a monastery lately founded by him at Hirfchau; and at the same time, in order that he might be enabled to pursue his studies with less interruption, he devoted upon another person the care of governing the abbey. In the following year the monks expelled him from his cell, complaining, that in consequence of his devoting himself to his studies, the necessary affairs of the monastery were neglected, and its estates suffered to be much dilapidated. He now retired either to St. Peter's Mount, or, as others report, to an humble apartment in the outer court of the abbey, where, he spent his time in devotion, the study of sacred literature, and the composition of his various writings, deaf to the repeated entreaties of the monks who exhorted him to resume his authority. In 847 he was elected to the archbishopric of Mentz, and in the following year he summoned a council, in which he procured the condemnation of Godoframe, for maintaining the doctrine of St. Auguistine respecting predetermination and grace. Rabanus died in 856, at the age of 71. He is described by Dupin as "having excelled all his contemporaries in the learning of those times, in explaining the principles of the liberal arts and sciences, and the rules of grammar and rhetoric; in a readiness in collecting from the fathers of the church common places upon the sacred scriptures; in allegorizing the historical parts of the bible; in an exposition of the mythical reasons of the ceremonies; in a facility at turning prole into verse, and in the manner of reducing all common places in precepts and instructions." And Molheim says "he is deservedly placed at the head of the Latin writers of this age; the force of his genius, the extent of his knowledge, and the multitude of productions that flowed from his pen, entitle him to this distinguished rank, and render improper all comparison between him and his contemporaries." He was denominated the great light of Germany and France, because from his fund of knowledge those nations derived principally their religious instructions. His writings were everywhere in the hands of the learned, and were held in so much estimation, that during four centuries, the most eminent Latin divines appealed to them for authority in religious matters. His writings consist of Commentaries on the Scriptures; Homilies on the Epistles and Gospels; Scripture Allegories; and a great many theological and literary pieces. Of which the most considerable number were collected and published at Cologne in 1627, in six vol. folio. Some other pieces of this author, not to be found in that collection, may be found in Baluze's "Miscellanies," among Father Sirmond's publications, and in the eighth vol. of the Collect. Concil. Molheim. Dupin.

RABASTENS, in Geography, a town of France, in the department of the Upper Pyrenees, and chief place of a canton, in the district of Tarbes; 10 miles N.W.E. of Tarbes. The place contains 750, and the canton 7422 inhabitants, on a territory of 150 kilometres, in 25 communes.

RABASTENS, or Rabastins, a town of France, in the department of the Tarra, and chief place of a canton, in the district of Gaillac; 21 miles S.S.W. of Alby. The place contains 6076, and the canton 812 inhabitants, on a territory of 152½ kilometres, in five communes. The principal article of its trade is wine.

RABAT, a town of Africa, in the empire of Morocco, situated on the S. side of the river Salle. Rabat had formerly, at intervals, a number of European factories; but the difficulty of navigating the river, the obstacles arising from the arbitrary power of the sovereign, and the disposition and prejudices of the Moors, have digusted the European. Nevertheless, Rabat is the most proper place for trade of any upon this coast, both for its vicinity to Europe, and the quantity of wool, leather, and wax, which it is capable of furnishing. From its central situation in the empire, it is also better adapted for the conveying of the commodities imported to every part of the country; but a despotic government acknowledges no principle but the convenience of the moment; it commands, judges, and executes, without considering either cause or consequence. At Rabat, near the mouth of the river, are the ruins of a castle, built in the twelfth century by Jacob Almanior, but entirely destroyed by the late emperor. The walls, which still remain, are near two miles round, and fortified by square towers. They enrole the castle, the town of Rabat, and a large space of ground where J. Almanior built beautiful palaces, and laid out delightful gardens, watered by plentiful streams, which he brought from the neighbouring springs. These walls, as well as the palace and the town, were built by Spanish slaves, whom he took prisoners in his first campaign. Within the same inclosure he also built a very large mosque, of which the ruins still remain. The roof was supported by 360 columns of rough marble. Near it was a handsome square tower, strongly built with stone, near 200 feet high, and called the tower of Hassan. From this tower may be had an extensive view over the sea, and ships may be discovered at a prodigious distance. This monument is in almost perfect preservation. There are some docks for building ships both at Sallee and Rabat; but the difficulty of navigating the channel, and the probability that the sand will continue to accumulate, give ground for apprehending, that very soon, only vessels with ears will be able to enter the river. Cherrier's "Morocco," vol. ii.

RABAT Affirmatian, a town of Persia, in Faristan; 120 miles E. of Schiras.

RABAT Arabia, a town of Persia, in the province of Kerman; 80 miles E. of Kervan.

RABAT el Cadia, a town of Persia, in the province of Kerman; 40 miles E. of Malatla.

RABAT Maaslud, a town of Persia, in the province of Kerman; 60 miles N. of Kabis.

RABAT el Nijfa, a town of Persia, in the province of Kerman; 60 miles N.E. of Malatla.

RABAT Shebariflan, a town of Persia, in the province of Chorafan; 260 miles N.E. of Isphahan.

RABATE, in Falconry. A hawk is sometimes said to rake, when, by the motion of the band of the bearer, the lure, call, &c. she leaves pursuing her prey, or quarry, and recovers the fit.

RABAT, in Commerce. See Rabat.

RABBIA, in Ancient Geography, a town of Judea, which belonged to the tribe of Gad; situated upon the torrent of Jaba; it was besieged by Josab, after he had defeated the Ammonites. Here was seen the head of Go, king of Bashan, who alone remained of the race of giants.—Alfo, a town of Palatine, in the tribe of Judah. See Rababah.

RABBATH-AMMON, or Philadelph, a town of Asia, situated in the mountains of the southern part of Palatine: S.E. of Tiberias, and S. of Botra.

RABBATH-MOAB, or Arcopolis, a town of Asia, situated at some distance to the east of the lake into which the river Jordan discharges itself.

RABBEN, in Geography, a small island in the gulf of Bothnia, N. lat. 63° 14'. E. long. 22° 14'.

RABBET, in Carpentry, is a deep groove or channel, cut in a piece of timber longitudinally, to receive the edge of a plank, or the ends of a number of planks, which are to be securely fastened in it. The depth of this channel
is equal to the thickness of the plank, so that when the end of the latter is let into the rabbet, it will be level with the outside of the piece. Thus, in ship-carpentry, the ends of the lower planks of a ship's bottom terminate upon the stem-fore, and the stern-fore abaft, with whose sides their surfaces are even. The surface of the garboard freek, whose edge is let into the keel, is, in the fame manner, with the fide of the keel at the extremities of the veffel.

RABBET-PLANE. See PLANE.

RABBETING, the planing or cutting of channels, or grooves, in boards.

RABBI, or RABBHIN, a doctor or the Jewifh law.

The word in its original, Ῥαββίς, signifies master.
The words rabbi and rabbin have the fame fignification; yet is there fome difference in their use. When we speak absolutely, and without applying the term to any proper name, we fay rabbin, not rabbi. Thus we fay, it would be unjust to attribute to the ancient rabbins all the notions of the modern ones.

On the other hand, when we prefix the term to the proper name of fome Jewifh doctor, we fay rabbi, not rabbin; rabbi Salomon Jacob is of this opinion.

Yet rabbi having no plural, we fay, the rabbins Juda Chiug, and Juda ben Chabin, are the authors of two ancient Hebrew grammars.
The title rabbi is faid to have been firft allowed, as a diftinguifhing title of honour, by men of education, about the time of the birth of Christ; though perhaps it has been anciently given to fome magiftrates and officers of fale, and to fome who were of fuperior rank and condition in life. See Esther, i. 8. Jer. xli. 1. Job, xxxii. 9.

The firft Jewifh rabbi faid to have been diftinguifhed with any title of honour, was Simeon, the fon of Hillel, who fucceeded his father as president of the fanhedrin; and his title was that of rabban. The later rabbins tell us, that this title was conferred with much ceremony. When a perfon had gone through the fchools, and was thought worthy of this degree, he was placed in a chair raised above the company; and then were delivered to him a key and a table-book; the key as a fymbol of the authority conferred on him to communicate the knowledge he had acquired, which key he wore as a badge of honour, and when he died, it was buried with him; and the table-book was a fymbol of his diftinction in his studies, and defire of farther improvement. To these ceremonies were added the imposition of hands by the delegates of the fanhedrin, and the proclamation of his title. It has been difputed, chiefly between Vitringa and Selden, whether our Lord had taken the degree and title of rabbi in the Jewifh fchools; Vitringa maintains the affirmative, and Selden the negative. See Jennings's Jewifh Ant. vol. i. p. 400. 3 &c.

The Jewifh writers diftinguifh betwixt the titles rab, rabbi, and rabban.

In the Old Testament we find the term רב, rab, in com- pofition with fome other words, employed as a name of office and dignity, but not till the people became acquainted with the Chaldeans, concerning whom only it is used. The word, both in Hebrew and in Chaldean, signifies fometimes great, fometimes many, and when used fubfiantively, denotes one who is at the head of any bufinefs, of whatever kind it be. Thus רב בּוֹקֶב, rab bukeb, is, in the L.XX., τιμωροις, and מנהגין, rab lechaim, τιμωροις, and מנהגין, chief cook. (Jonah, i. 6. Jer. xxxix. 11, see also Dan. i. 3.) It is used in the plural also for chief men in general, superintendents, or thofe at the head of affairs. Thus רב שׁים, rab shem, rab hamnachal, are the chief men employed by the king over the different departments of the flate. (Jer. xxxix. 13.) The original term fignifies entirely the import of the Latin word princeps, but not of the English word prince, at reft in its fmall common acception; for they are not the king's fans, or nobles of any order, who are fo denominated among the Chaldeans. The word evidently appears to have been equivalent to the term רבע, zbar, among the Hebrews. Accordingly, he who is called Daniel, in the above cited paffage, רבע fer ū, is, four times, in the fame chapter, called דוד יב, zbar baferū, (Dan. i. 7, 9, 18.) And this name of the name rab seems to have continued long in Syria, as well as in Chaldea. Thus in the Syrac New Testament, it is found in the fame manner, united with the common appellation of any fome of office, in order to denote the principal perfon in that office; thus, דוד-רכה, (Matt. xxxvi. 51.) is the high prieff, דוד--orders (Luke, xix. 2.) is chief of the publicans, and דוד- TestBeda (1 Pet. v. 4.) is chief fhepherd. Rab, contrived in this manner, is equivalent to the Greek ραββις, as used in condemnation. The preceeding titles are accordingly thus exprefled in Greek, ραββις τιμωροις, and ραββις καθήμενοι.

Again, the word rab is sometimes found in that version, combined not with the title of any of officer, but with a term denoting the office or charge itself; in which case it always means the perfon who is principally entiftled with the bufinefs. Thus, rabba (Matt. xx. 8.) is the fcholar, תור ראב, he who is over the household; and נביב (Mark, v. 35.) is the ruler of the fynagogue, נביב. It is not unlike, though no example occurs in fpitrite, that the term has at firft been fimilarly compounded with fome word fignifying a fchool, or, perhaps, with the name of the art or science taught, in order to denote the overfeer of fuch a fcherny, or the teacher of fuch an art. When the term rab came to be properly applied, as an honourable confellation of the learned, the word with which it was, at firft, for distinction's fake, compounded, would be superfeffed as unneceffary. It is, at leat, certain, that the Jewifh doctors, who refided at Babylon about the time of our Saviour, were called simply rab. But in the Old Testament there is no trace of fuch a title as rab, rabbi, or rabban, given to a man of letters; nor is any one of the old prophets, or fcribes, or indeed any other perfon, diftinguifhed by this mark of respect prefixed to his name. Although the introduction of titles is always occafioned by the erection of fificial important offices, it is commonly in the decline of merit that fonorous titles are most adopted. At firft, without doubt, vain-glory has led many to afume them, to whom they did not belong, in right of office, and an interefled adulation has induced others to give them. Some of them, however, came from, among the Jews, to be converted into a kind of academical distinctions, which, in order to give them more weight, are faid to have been conferred folemnly in their fchools or colleges, accompanied with certain religious ceremonies. From this practice of giving literary degrees in Christian universities, to which there is nothing fimilar in all Pagan antiquity, either Greek or Roman, but to which the Jewifh efuun above-mentioned bears an evident and clofe analogy.

As for rab and rabbi, the only difference, it hath been faid, betwixt them is, that rab was the title of fuch as had had their education, and taken their degree in fome foreign fchool; e. g. at Babylon; whereas rabbi was the title of fuch as were educated in the land of Judea, and more honourable than the other. But the higheft and most honourable title was rabban; which, they fay, was never conferred on more than feven perfons; viz. on R. Simeon, live of
his descendants, and R. Jochanan, who was of a different family.

Those who belonged to the Jewish schools were divided into three classes or orders. The lowest was that of the disciples or learners; the second, that of the fellows, or companions, who, having made considerable progress in learning, were occasionally employed by the masters in teaching the young students; and the highest was that of the preceptors, or teachers, to whom they appropriated the respectful title of doctor, or rabbi, differing, as some have said, from rabbi only by the addition of the prefix pronoun of the first person. This title rabbi was the highest academical honour. In the gospels, ἱεροσολύμων is given as the Greek translation of the Syriac rabbi. (John, i. 38.) Yet this word does not, as the Greek, literally signify teacher; but, having been conferred at first, as a mark of respect on actual teachers, and afterwards on other learned men, was justly accounted as apposite a version as the Greek language afforded.
